GARDEN.

VOLUME V., NEW SERIES.

VOL. XXX., OLD SERIES.

LONDON:
PUBLISHED FOR THE PROPRIETORS, 162, FLEET STREET.

1863.

LONDON :

PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,

17, JOHNSON'S COURT, FLEET STREET.

TO OUR READERS.

At the close of another Volume, and, in this instance, at the close of another year, the Editors have again to give expression to their gratitude and their hopes. On no one of the twenty-nine occasions on which they have thus addressed you have they in any degree exaggerated the similar feelings which influenced them; and the successes and the onward prospects which on those occasions justified their words are still more justifying now.

They turn over the pages of the Volume just concluded, and to which this Address is to be introductory, and they fear no contradiction to the dictate of their judgment that—it is more than equal to any one of its predecessors in the useful information it contains.

Then as to the future. The portrait within this Volume reminds them—were a reminder needed—that one of the most able of the contributors to this Journal will enrich its pages no more; yet, as statesmen have observed in far more momentous transactions, the Editors have found that when a need for aid is acknowledged, efficient volunteers always step forth and render that need but transient.

Those who are insensible to the approbation bestowed upon them by competent judges are devoid of one of the most efficient promptings to efforts for the attainment of excellence. The Editors do not pretend, therefore, to any such insensibility, but acknowledge the high gratification they felt on hearing recently from one who is now the oldest member of their staff, that a gentleman of no small note concluded his observations on these pages by saying—“That Journal is independent, and I have never found a sentence in it unworthy of a gentleman.”

Those are characteristics the Editors have always coveted, and never more so than for the two Volumes which will comprise the Journals of 1864; for the Editors foresee that during its days events and topics appropriate to their pages are likely to occur which will require even more than the usually-needed firmness and good temper.

INDEX.

- ABERDEENSHIRE, GARDENS IN, 168
Abergavenny Poultry Show, 301
Acacia grandis not flowering, 360
Acclimatisation in the antipodes, 524
Adelmenes, wintering, 338
Adelaster albivensis culture, 439
Adenium obesum, 471
Aechmea culture, 291
Agaricus fertilis, poisonous, 395
Agave lurida, 191
Agricultural Hall Flower and Fruit Show, 162, 185; Poultry Show, 176
Aldborough and Boroughbridge Poultry Show, 157
Alexandra Park Exhibition, 66, 82
Alismas, 249
Allamanda nerifolia, treatment of, 518
Allium fragrans, 259
Alocasia—metallica from eyes, 9; metallica culture, 214; Lowii culture, 319; macrorrhiza variegata, propagating, &c., 419
Aloe, of Vera Cruz, 191; American, blooming, 208
Alyssum saxatile variegatum to propagate, 154
Amaranthus melancholicus ruber, culture, 30, 108, 110, 141, 145, 151; wintering, 128; as a bedder, 205; bicolor and tricolor, 251
Amaryllis—longiflora rosea falling, 37; Regina spectabilis, 113; belladonna culture, 134; neglected, 307; failures, 329; culture, 518
American—kitchen gardening, 230, blight, 498
Ammonia—in the atmosphere of hot-houses, 326, 329, 330; in air of plant-houses, 333; for grass land, 411
Ammoniated oxide of iron as a manure, 490
Anchomeres Hookeri pallida, 113
Androsace lanuginosa, 367
Annals, list of early, 400
Anomala cruenta sowing, 319
Ants invading wall-fruit, 338
Aphelandra Leopoldi culture, 298, 478
Aphides and two of their enemies, 53
Aparian notes, 243, 302

From observations taken near London during the last thirty-six years, the average day temperature of the week is 74.5°, and its night temperature 51.0°. The greatest heat was 92°, on the 12th, 1859; and the lowest cold, 35°, on the 7th, 1860. The greatest fall of rain was 1.10 inch.

PLANTS SUITABLE FOR A GRAVE.

UNTIL public taste submits to well-chastened rules, it is difficult to say how far it may go astray in its anxiety after novelty even in this, the most solemn of all the instances in which it exercises its avocation—the decoration of the resting-place of the departed. It affords little surprise, therefore, that now and then an authority, armed with the necessary powers, enforces views differing considerably from the wishes of those who would like to do as they pleased with the surface earth above a departed relative. Certainly no assemblage of objects presents so much diversity of ornament as the fashionable cemetery of the present day. A company of well-dressed people, conforming as they invariably do to certain conventional rules,

have so many things in common, that in point of diversity they are tame compared with the fancy tomb and its accompaniments.

This growth of fancy is of recent date, for our old churchyards present but little variety. Certainly the local custom of one neighbourhood differs from that of another a hundred miles or more away; but in each the changing events of a couple of centuries have made but little change in the manner in which the graves of the dead have been honoured by the living. But it is not our province to give any opinion thus upon the stone, marble, and metallic enormities.

Another feature has been added which, perhaps, has given rise to as much angry feeling as that of the sculpture amongst those who assume to have the direction of matters of that kind—the planting of flowers upon and around a grave; and it is in answer to a query from a correspondent, "What kind of flowers ought to be planted there?" that I with some unwillingness address myself to the task of giving my opinion on the subject.

Although the decoration of the graves of departed friends with flowers is of great antiquity, and has been kept alive by the stirring appeals of the poet as well as the writer of romance; yet in many parts of England it has either fallen into disuse or has never been practised at all, and it is questionable whether it has ever been so popular in any part of England as it is in The Principality. The impetus, however, given to it by the customs of many of the well-to-do in the example they set in decorating the tombs of their friends in our public cemeteries

may, doubtless, find an echo in the other classes; and after some extraordinary attempts at novelty made by some of the more ambitious something like uniformity may, perhaps, be at length arrived at, and the extravagant idea too often displayed may receive such an amount of public censure as to make it a matter of wide exception.

Assuredly the simplicity of our primitive fathers never contemplated that the decorations of the graveyard should compete with the parterre, although the latter at that early period was of meagre extent as compared with its magnitude now; and most likely the system of planting flowers over a grave had its origin in the first instance in gathered flowers being scattered there. The sympathetic mind of the poet can easily suggest to itself the innocent gambols of young children, plucking the Violets, Primroses, and other wayside flowers that came in the way of their accompanying their only remaining parent to visit the grave of her much-loved partner. It is very easy to picture her seated on the grassy mound, the turf from its recent disturbance having a withered and uninviting appearance; and it requires no great flight of the imagination to conjecture the tiny lapfuls of Daisies, Buttercups, and Violets of the little flower-gatherers left as an offering on their father's grave; while on a second visit the mother's ears are saluted on the journey by the news that the eldest of the little party in plucking a Violet pulled up a plant also, and suggests it might perhaps grow on some naked place on "father's grave," where the turf did not meet. Transported there, it grows, is carefully watched, and at each visit its history and how it came there is brought to mind; and another naked place being perceived, a plant is this time sought for and brought to occupy the vacant spot. From such beginnings it is likely we owe our somewhat overstrained mode of ornamenting the grave with the gayest ornaments of the flower garden. Observe, I say "overstrained notion of ornament," for I by no means fall into the views of those who think such things suitable there, however much it may be desirable to do honour to the remains of those gone from us. Certainly the feelings which prompt such offerings are of more consequence than the offering itself; but society at large would speedily make unpleasant remarks if some mourner at a funeral attended that ceremony attired in the gayest colours that fashion commands in the ball-room. It would be held as a poor excuse for such an unusual departure from established customs to be told that "respect for the dead" prompted the bearer to array herself in that way.

Following out the sober idea of suiting the ornament to the purpose, let us see in what way the "little spot of ground"—the final earthly resting-place of each of us, or of such as may be so honoured, may be beautified without any departure from the feelings which ought to pervade such a place.

I by no means object to all floral decoration, but as far as possible I would advise its being with low-growing indigenous plants, and more especially such as flower early.

Of such, many reasons point out the Violet as one of the most suitable. Lowly and unassuming in its outward character, its beauties and its worth are ascertained by a closer acquaintance; besides which, there is something almost hallowed in the name, and I would in this instance go as far as to allow the cultivated variety to be substituted for the wild one.

Next to the Violet we have the Primrose, than which neither the flower garden nor the hothouse possesses a more lovely gem. If more variety than the wild one be wanted, the double one of the same colour, or the double or single white, might be admitted; but I would not advise the dark-coloured ones.

Primroses and Violets are unquestionably the most important of our graveyard plants; although closely following on them, and perhaps in some instances, as in that of beautifying the resting-place of a child, the Snowdrop becomes appropriate; and this early harbinger of returning spring may also be planted on every grave almost, where its unassuming flowers present to the pilgrim the first of Nature's gems of the season. Contrasting, therefore, so well with the herbage which afterwards succeeds it, the Snowdrop is by universal consent an acknowledged legal occupant of the grave.

I am far from acknowledging the same right to its neighbour in the garden—the Crocus. Its foreign origin and gaudy hue seem to point out a place for it elsewhere. If, however, the taste of the party interested decide on the Crocus, I would confine the colour used to white, or, in stretching a point, blue might be added; but I think yellow too glaring to harmonise with other sober objects around it.

I believe with these few and simple flowers my ambition in doing honour to the grave would be satisfied, as all might be planted on an unprotected mound, and all survive the rough ordeal of the scythe. It would, however, be as well to mention here plants adapted to certain localities which might with perfect propriety be included also in our category. In dry soils partaking of the sand the little Stonecrop (*Sedum acre*), might be advantageously used. In like manner on a chalky soil the wild Thyme might form a useful adjunct; there is something appropriate in the sound of the name of the latter.

On soils of an opposite character, shady and moist, some of the Mosses might form useful adjuncts; and here, again, the plant by its name speaks poetically to our feelings. And while we in all instances would allow the turf to a certain extent to occupy the prominent part of the "sod" which overlies the remains of a departed friend, a judicious admixture of the plants mentioned above may form an ornamental feature to an unenclosed grave better than the rough herbage which otherwise might occupy the place. The pretty little grass-like plant Thrift might, however, be admitted, and might form a useful feature on exposed places near the coast; and a neat-growing little herbaceous plant, an Everlasting, might be introduced as a fitting object here also.

Observe, I have advised the adoption of only low-growing plants as fitting memorials of such a place. The Wallflower which grows on some church walls and on some ascends to the summit of the tower, sowing itself abundantly below, is nevertheless in my opinion unsuited to the grave. In like manner Snapdragon, which I have seen take possession of a wall at a great elevation, as well as Valerian, are plants all too tall to meet the requirements of what I would lay down as a standard in such cases.

The herbaceous flower-border affords several more plants of great beauty and suitability; but I am unwilling to allow any but those of home origin a place among our British dead. Much has been said about the Rose, and it is almost sedition to say anything against this acknowledged queen of flowers; but I am far from certain that the graveyard is a fitting abode for her.

The time-honoured custom of associating the sombre Yew with our graveyards has in all likelihood led to the Cypress being a subordinate appendage to the same object, and small Cypresses are frequently studded around sculptural ornament. This, of course, is confined to the more affluent, and deserves a notice hereafter; but I would ask a very homely question of those who recommend such aspiring plants as Cypress and Juniper to ornament the graves of a crowded churchyard, what it would look like if every grave

in the place were similarly planted? It would be a perfect shrubbery lacking the variety observable elsewhere. Besides, a grave planted with shrubs or high-growing plants conceals from view the sight of several of the graves beyond it, thereby acquiring exclusive attention from passers-by. More might be said on this head, but I leave it and pass at once to another feature in graveyard or cemetery decoration—that of the enclosed plots called family graves.

Belonging as these objects do to the wealthier classes of society, we might reasonably expect in these tokens of a refined taste. It is much to be feared the spirit of competition has much to do with the pageantry to be found here. Of sculptural ornament it is not my province to speak; but can anything be more at variance with the quiet solitude by which the spot is invested than the glaring colours by which it is too often decked out? An enclosure containing white stone or marble sculpture is surrounded by ironwork often bronzed or gilded, and through the openings are seen the brightest scarlet Geraniums and yellow Calceolarias that the florist can furnish. It may be that my ideas lag behind the spirit of the times; but I nevertheless have no hesitation in putting them forth as opposed to this glitter.

The gayest part of the parterre cannot exceed what is seen sometimes around a grave. Assuredly there is a proper place for everything. Elsewhere the Verbena, Lobelia, and Petunia look well, but a grave is not the place for them. That plants are necessary there I admit; and those proper for such a small plot as is sometimes enclosed render it anything but easy to suggest what is best suited for it; and I hope some of your readers will impart their opinions on this matter. My own are as follow:—

If it were possible to retain the verdure of the turf, short, thick, and velvety in the uniform condition it is seen in when at its best, as in showery weather in May after it has been recently mown, I do not know of anything which could improve it; but the ever-changing features of vegetable life render a certain amount of labour necessary to keep turf in order. This is not always convenient to those who reside at a distance from the spot. Something, therefore, that would form a substitute for grass in small isolated spots is much wanted; and when *Spergula pilifera* was announced to the gardening world as an acquisition likely to supersede turf, not requiring any mowing, &c., I was in hopes we had a plant in many respects suitable to decorate the grave. Unfortunately, with me at least, the plant has been a complete failure; and we must select something else as a substitute for that sod which is destined to cover the remains of all that is left of mortality.

A plant that would look well at all times, and without the trouble which grass entails, would be a great acquisition. The compact habit and deep green foliage of *Saxifraga hypnoides* give it strong claims to our notice, and I am in hopes it will answer. There is, however, no reason why some of the flowers mentioned as applicable might not also be adopted here; and perhaps a dwarf Rose might be introduced, a miniature Cypress or two, or a small stunted Yew, which may have previously been kept in a flower-pot, and to keep it dwarf may still be kept plunged in that condition; but gay summer-flowering plants, such as are usually called bedding plants, ought not to be used.

Certainly some little order and appearance of cultivation may be shown. The plants may just touch each other, but need not crowd. Supposing a plot 6 feet square required planting, there might be one or two dwarf Cypresses, just as the number of graves required. These might stand near the head, and the remainder of the space dotted over with patches of Violets, Stonecrop, *Saxifraga hypnoides*, or *S. tri-dactylites*, which becomes an excellent and closely formed cushion of the deepest green; a patch or two of Primroses, which if removed when done flowering might give place to a dwarf Plox, of which *P. subulata* is very good; and I am not certain but that the deep green foliage of the *Saxifraga* might allow an *Auricula* by the side of it. Snowdrops, of course, must not be forgotten; and there is a dwarf Everlasting, the foliage of which, as well as its flower, looks well at all seasons. With these I should say be content; or if some of them were omitted it might perhaps be as well. It is, nevertheless, not unlikely but another set of plants might be adopted by some or else equally well adapted for the purpose.

Before concluding, I may add that I by no means disapprove of the culture of flowers in a public cemetery, although I cannot see in which way the undue preference given to bedding plants can be recommended on any plea excepting that of gaiety at one particular time, and that not of long endurance. Assuming, as is very often the case, that a circumferential border exists, shutting the interior from outward objects, evergreen shrubs ought to predominate on this border, so as to give it a clothed appearance in winter; while in the front of this border may be cultivated a great diversity of flowers. I will not say that it may be converted into a fashionable ribbon-border, but many of the plants so used may have a place here, planted amongst others of their height and character. This may be a feature in the exterior border, but the clumps or beds that diversify the centre ought to be more sober in their exhibition of floral gaiety, while evergreens must predominate still more extensively. Nevertheless, such plants as Pinks, Iberis, Arabis, &c., might be grown to advantage; and nothing looks better than the double white Rocket, for with so much turf and evergreen white or light-coloured flowers will tell to most advantage, and there are several of the hue—as, for instance, some Campanulas, white Phloxes, and I cannot see any objection to patches of Cerastium ornamenting the front; but beyond this most if not all the other bedding-out plants must keep outside.

It is needless for me to follow this subject further; but I hope others will favour us with their opinion, as it is a topic deserving the notice of those best qualified to take of it a just view, and a series of letters in *THE JOURNAL OF HORTICULTURE* would be of service. J. ROBSON.

CULTURE OF ROSES IN POTS.

THIS is a topic of general interest, although the following is a reply to "R. S., Bristol," who asks for information how to grow potted Roses in quantities.

Although you do not say so, we infer that your object is to get up a stock of Roses in pots, for blooming under glass in spring and early summer, and there is scarcely any other object in the whole round of gardening that is so likely to prove a source of pleasure to those who are fond of that which is sweet and beautiful. Supposing, then, that you desire to have Roses in bloom next spring, there are two ways by which your end can be attained. You can either procure plants that are already established in pots and in a fit condition to be gently forced into bloom, or you can get plants from the nursery-rows in autumn and pot them yourself. And as it is your object to grow extensively, the latter is the course that is to be recommended, as being not only the cheapest way of obtaining a large stock, but will, by following the directions which shall here be given, prove perfectly successful.

You should go to some good Rose-nursery early in autumn, and get the first pick of the number you require from the nursery-rows. Choose those that have broken from three or four buds, that have made half a dozen strong healthy shoots and have stocks only a few inches high, or, perhaps, better still, that are grown on their own roots. Let your selection be marked, and having secured them, leave them where they grow till the middle of October, about which time they have generally pretty well matured their growth and are shedding their bottom leaves. This is the proper time to lift and pot them with the view of getting them to form fresh roots before winter, and by gentle forcing to secure a crop of bloom the following spring.

The plants should be lifted with care, preserving every twiggy root, and shortening with the knife those that are strong and pithy. Pot them firmly in pots ranging in size from 6 to 8 inches. The soil most suitable for them is a rather heavy loam, with about a third of well-rotted hotbed manure or cowdung, with a slight addition of road grit or coarse sand. The pots should be well drained, and in potting the roots should be nicely distributed among the soil. When potted and watered plunge them at once in a pit or frame where there is a gentle bottom heat. Keep them rather close for ten days, and when the days are dry syringe them morning and afternoon, and keep them shaded from the sun. After the first fortnight the lights may be taken off

them for a few hours in the morning and evening, always putting the lights on for the night; but do not shut them down closely.

The gentle bottom heat and the close moist atmosphere will maintain the action of the roots and leaves, and by the end of November they will have made fresh roots to a considerable extent, and the buds on the last season's growths will be as firm and prominent as those which have not been disturbed at all. The leaves will be all shed, except a tuft at the top of each shoot. If by this time the bottom heat has not entirely gone, they should be removed to some cool place. Their removal from such quarters will in most cases be a matter of necessity, as few are the places where there is such accommodation to devote to wintering plants that can be otherwise protected. They can be plunged in some sheltered place where heavy rains and severe frosts can be guarded against. Sawdust or cinder ashes form excellent material for plunging in, as either of these is not so subject to the destructive inroads of worms, and forms a better protection to the roots than common garden soil.

The time to prune Roses thus treated must be regulated and determined by the time that they are required to bloom in spring. In our own practice we have several times had Roses in bloom, under similar circumstances, early in March; and when required so early they should be pruned by the middle of December. It gives the plants a much better chance the first year; and, looking at them as permanent objects, it is far the best way to keep them at rest till the middle of February. Let it, however, be supposed that you would desire a few of them to flower in March, that few must be pruned at the time named above. Cut them back to two or three eyes, according to the strength of the shoots, always cutting more closely in the case of the weaker growths.

By the first week of January they should be introduced into a temperature of 45° to 50° at night, and if they can be afforded a bottom heat of 60° it will be much to their advantage in causing them to break regularly and strongly. They should be kept near the glass, and be freely syringed with tepid water at least twice a-day—morning and afternoon.

As soon as the shoots attain about an inch in length increase the temperature by 5°, and on every favourable opportunity admit a good supply of fresh air. Keep them away from the heating apparatus, and shut up early in the afternoon with a moist atmosphere. There are few things more adverse to Roses than a dry parching atmosphere. Increase the temperature gradually to 60° by the time they show their bloom-buds.

Green fly is a great pest to forced Roses, and must never be allowed to gain a footing; but their most treacherous and destructive enemy is the small black maggot, with which all Rose-growers are familiar. It folds itself up in the leaves, from which retreat it sallies and eats into the centre of the Rose-bud when little larger than a pea. There is only one way, that I am aware of, that you can cope with this enemy, and that is to look over the plants every day; and wherever you see the leaves folded up, or sticking two together, there you will find a maggot which you will destroy with a hearty good will, and put an end to his gluttonous repast. When the buds show themselves above the foliage, be sure to give a free admission of air on all occasions when weather will permit, at the same time avoiding currents of cold air. If this is not attended to, the flowers and their stems will be weak and short-lived.

Immediately the flowers begin to show their colour the plants must be removed to a house where the temperature ranges about 55°, giving the plants plenty of room, light, and air. Here they will not only open their flowers with a higher colour and a greater perfume, but the stems and leaves will acquire a degree of stiffness and strength so desirable in Roses, and which cannot be attained in a higher temperature and a moister atmosphere. When in full bloom a temperature of 50° is sufficiently high. Under such circumstances they will remain in bloom a long time, more particularly if shaded from the sun, and carefully attended to with water at the root—that is, if the soil is preserved in that genial condition so commonly described by gardeners as "neither wet nor dry." Under such circumstances as these you can have the enjoyment of a display of this queen of flowers next March; but as already stated, it is the better

way for the plants to let them break the first season of their own accord, and let them be bloomed with less artificial heat.

When the plants have done flowering they should by all means be as carefully attended to as if they had yet to bloom. It is too often the case that forced plants are sadly neglected and mismanaged after having yielded their crops of bloom for the season. They should be gradually hardened off and not placed out of doors till all danger from frost is past. If then lifted in the autumn they were potted into six and eight-inch pots, the strongest of them should be shifted into pots two sizes, and the weakest into pots one size larger. When shifted it is of great advantage to them to be kept under glass for a week or two after. This is presuming that they are lifted before all danger from late frosts is over; but, when shifted later in the season, they may be plunged out-doors at once. Choose a sheltered situation where they can at the same time have all the sun possible; give them plenty of room, and see that the material in which they are plunged is sufficiently open, and the site well drained, so that no stagnant water can stand about their roots, otherwise they would rot, and as a consequence the foliage would become yellow and drop off, leaving you with unripe and diseased plants. Roses, and in fact all other plants intended to be forced, should never be, as is too often the case, plunged in damp shady situations. Throughout the summer endeavour to supply them with water sufficient to keep the soil at all times in a healthy growing condition; and should worms find their way into the pots, water with clean lime water.

If worked on briars keep them free from suckers, and remove all flower-buds as they make their appearance, except in cases where Roses may be required in November; then Hybrid Perpetuals may be allowed to bring forward the buds which they form after the middle of August; and by placing them in a cold pit or frame, and later in the season encouraging them with a little fire heat, they will expand and last in flower a long time. This practice is not, how ever, to be recommended, except you intend to grow a large stock of plants, as such treatment is not favorable to their successful forcing in spring; and I should think in your climate your Rose out-doors can be had in flower late in the season.

When the plants have mostly shed their foliage, and presuming that you intend to force a portion of your stock early, the best-ripened plants should be pruned. Then turn them carefully out of the pots, and examine the drainage, and get rid of any worms which may have intruded. When worked on the briar root it frequently happens that the stock gets green and mossy; whenever such is the case, let them be dusted over with quicklime, which will destroy the parasites. Remove the surface soil, and replace it with fresh rich soil, and when intended to be forced only they should be placed under glass at once. A cold pit or vinery will be a good place for them, if you desire a constant succession of flowering plants till Roses are in bloom in the open ground.

Continue throughout the winter to prune a convenient number, always putting them under glass as soon as they are pruned. It is always best not to put them into heat till after they have been under glass in a cool structure for a fortnight after they are pruned. Be reminded all the time that it is only recommended to have them out of doors in winter, in case of your not being able to afford them the protection of a pit or frame. It not infrequently happens that those pruned in February, and let out of doors, have their buds crippled with March frosts, for spare corners on long glass are very scarce now-a-days.

It frequently happens that those forced the second season after being lifted in eight and ten-inch pots, require nothing further at the root the third season than simply to see to the drainage, and to remove a portion of the soil from the surface of the ball, and replace it with rotten dung and loam in equal proportions. This, of course, entirely depends on circumstances. If the roots have made their way down to the bottom of the pots leaving a large portion of the top soil inert and unoccupied, they should be partially shaken out, have the strong roots pruned back, and in repotting a good portion of the soil be placed below the roots. My practice has been to shake them out and treat thus every

second year, and to root-prune them in a similar manner to that practised with the Geranium, only not so severely. It is not only possible to keep them healthy and in moderate-sized pots for many years by this process, but they seem to rejoice in the operation, starting off with increased vigour with every application of fresh soil.

In making a selection of Roses for forcing you should select the greater portion of your stock from the Hybrid Perpetual section. Most of the Teas are beautiful for pot-culture, but generally speaking do not bear early forcing so well as the Hybrid Perpetuals. Then there are Provence, Cabbage, and Moss Roses, so beautifully fragrant.—D. THOMSON.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION. — JULY 1.

THE horticultural campaign began early this year, and it has closed at that period of the season when Londoners begin to consult their "Bachelors," and when "Murray" is greatly in request. The rival claims of the south coast and its soft sea breezes and sunny sands, the picturesque scenery of the Chamberland lakes, and the heathery mountains and deep glens of the Highlands, are now becoming matters of anxious deliberation; those who have country seats to retire to are beginning to think of a change of quarters, and in another month London will have gone out of town. It was, therefore, we think, wisely determined that the last great horticultural display for the season should take place before this periodical migration commenced.

The Royal Horticultural Society is not remarkable for its good fortune as regards weather, and when it does have a wet day for one of its exhibitions the fact is sure to be expatiated upon, and not infrequently with some embellishments, and it is, therefore, only justice to say that no day could have been finer than Wednesday last; genial in temperature, with a bright but not overpowering sun, whilst a gentle breeze kept the air from stagnation, it was just the day that one would have chosen for out-door exercise.

As on former occasions the plants and cut flowers were arranged along each side of the nave of the International Exhibition building, the hot dry atmosphere of which, it may be remarked, caused many of them to give evident signs of flagging, whilst the Fruit was allocated in one of the refreshment-rooms, involving a voyage of discovery to find it out. Many must have failed in the attempt; for, contrary to all wont, the attendance of visitors to this part of the Exhibition was unusually thin, notwithstanding the high character of the productions which invited their inspection.

The absence of the grand specimen stove and greenhouse plants, as grown by Messrs. Whitebread, Green, Peed, and others, which constituted so important a feature in previous exhibitions, was also much to be regretted, as it deprived the Show of much of its effect; and this want the Roses, fine as they were, and forming as they did a principal, and, indeed, the most attractive portion of the Exhibition, did not fully compensate for.

FINE-FOLIAGED AND VARIEGATED PLANTS.—Many large and handsome specimens of this description of plants were exhibited, including Crotons, Alocasias, Caladiums, Latanias, Dracenas, Arancarias, and a variety of others. Amongst Nurserymen Messrs. J. & C. Lee took the first prize with a collection in which were a noble *Alocasia metallica*, a large and very fine *Cordyline indivisa*, *Cyathia Smithii* with its handsome lively green fronds, *Cibotium princeps*, *Rhopala magnifica*, and *Caladium Baraquini*. Messrs. A. Henderson and Co. had the second prize for *Alocasia macrorrhiza variegata* and *metallica*, the narrow-leaved *Croton angustifolium*, the elegant fern-like *Jacaranda filicifolia*, *Dracena ferrea* and *cannaefolia*, *Dieffenbachia maculata*, *Maranta variegata*, *Caladium Chartisti*, and other plants. Mr. Bull, of Chelsea, was third, and he had some magnificent plants; among which may be noticed a tall and very handsome *Rhopala coreoventensis*, *Dracena australis*, *Gleichenia flabellata* very large, *Pandanus utilis*, *Aracaria Bidwillii*, *Alsophila exelsa*, and *Latania borbonica*. In a collection from Messrs. Jackson and Sons, of Kingston, there were also several large specimens, including a noble *Alsophila australis*, *Corypha australis*, *Dracenas terminalis* and *ferrea*, and the variegated *Pandanus javanicus*.

Among Amateurs fine collections of ten came from Mr. Taylor, gardener to J. Yates, Esq., Highgate, and Mr. Smith, of Syon: the former taking the first and the latter the second prize. In Mr. Taylor's exhibition there were *Cycas revoluta* and *Dion edule*, both of them of great size, and a fine *Chamarops humilis*; and in that of Mr. Smith an immense *Latania borbonica*, *Croton pictum* of great height, *Calathea* or *Maranta zebra*, *Duranta Baumgardii*, and the *Wax Palm*, *Ceroxyloa andicola*. A third prize was awarded to Mr. Ross, of Newbury. *Phlebodium aureum* and *Coleus Verschaffeltii* in this collection were good specimens.

Prizes were offered for variegated Begonias, but we only noticed one collection, which came from Mr. Young, gardener to R. Barclay, Esq., of Highgate, and it received a second prize. It contained handsome plants of President Van den Hecke, Duchesse de Brabant, and grandis, also Charles Encke, Anna von Schonborn, and the better-known Rex, Marshalli, and Rollissoni.

Caladiums afforded a more extensive display, and from the diversity in the markings of their foliage were much more effective. Messrs. A. Henderson & Co. had the first prize for a fine collection, consisting of the pretty argyrifolius, Belleymei, Chantini, a handsome plant of bicolor magnifica, Troubetskoyi, a large plant of Wightii, picturatum, paele, and regale. Mr. Ingram, gardener to J. J. Blandy, Esq., Reading, had splendens, variegatum and others already named, and received the second prize; Mr. Young, Abern-man, coming in third.

FUCHSIAS.—These did not come up to our expectations, being exactly the same plants that were at the Royal Botanic Show the previous week, and much deteriorated from what they then were; exception must, however, be made in favour of Mr. Higgs, gardener to Mrs. Barchard, Putney Heath, who had a first prize for three fine standards, standing about 9 feet high, of Rose of Castille, Prince of Orange, and Venus de Medici, the heads being full of flower. For six plants Mr. Gardener, of Clapham Park, received the first prize for Fair Oriana, Senator, Wiltshire Lass, Madame Cornelissen, Rose of Castille, and Isa Craig, all of them handsome plants, and full of bloom. Next came Mr. Cannell, gardener to G. Jennings, Esq., of Clapham; and in the Nurserymen's class, Mr. Treen, of Rugby, had a third prize.

FERNS.—Several collections of these, both exotic and British, were exhibited, the latter proving to the majority of the visitors the more attractive of the two, and affording a relief to the eyes from the brilliant colours of the cut Roses. In the class for Exotic Ferns, by an oversight, apparently, on the part of the exhibitors, the requirement that the pots should not exceed 15 inches in diameter was not complied with. Such collections, consequently, were disqualified for receiving the amounts offered in the schedule; but extra prizes were awarded instead to Mr. Bull, Messrs. A. Henderson & Co. and Mr. Lavey, of Petcham, all of whom had excellent collections. That from Mr. Bull was the finest, all of the plants being large and handsome specimens. It contained two very large Cibotiums, Barometz and princeps, Alsophila excelsa and radens, Dicksonia antarctica, Blechnum brasiliensis, and Pteris natalensis. Messrs. A. Henderson and Co., whose plants were also very fine, had Cibotiums Barometz, Schiedei, Cyathea boconensis, Drynaria coronans, Brainea insignis, Phlebodium pulverulentum, a large Alsophila australis, Angiopteris erecta, and Drynaria mussefolia.

In British Ferns the finest came from Messrs. Ivey and Son, who had two collections. That which received the first prize consisted of *Athyrium Filix-femina* multiceps, corymbiferum, depauperatum, and plumosum; *Lastrea Filix-mas* cristata and Jervisii, *Lastrea decurrens*, *Onoclea sensibilis*, *Osmunda regalis* cristata, *Polystichum angulare* Elworthii and proliferum, and *Adiantum capillus-Veneris*. The other collection was also very select, containing, among others, the new forms of *Athyrium Filix-femina*, distinguished by the names of glomeratum, Iveryanum, and Applebyanum, and *Blechnum spicant* polydactylon. Mr. Salter also exhibited a fine collection, in which *Osmunda cinnamomea*, and spectabilis and *Struthiopteris pennsylvanica* were bearing panicles; and there were besides *Scolopendrium vulgare* polycarpus, a variety with the extremities of the fronds much branched, *Asplenium lanceolatum* microdon, and a handsome plant of *Lastrea Filix-mas* cristata. Mr. Lavey had likewise a second prize for an excellent collection, in which we noticed a

fine *Trichomanes radicans*, and some of the new forms of *Athyrium*.

NEW PLANTS.—These were sent in considerable numbers, some making their appearance for the first time, others having been already shown at previous exhibitions. Messrs. Veitch had two extensive collections containing many of their recent introductions from Japan, not the least important of which was the beautiful and sweet-scented *Lilium auratum*, already described in these columns, and of which a faithful representation is given in the *Florist and Pomologist* of September last. The specimen exhibited did not, however, give a fair idea of the great size to which the flowers attain—8 or 10 inches across—when produced from large bulbs. The hybrid *Cattleya* between *Acklandia* and *Lodigesi* was another beautiful and interesting object, and likely to prove but one of a number of other acquisitions in the same line; *Bomarea multiflora*, a greenhouse climber from Peru, with orange and scarlet flowers, is also a plant likely to prove an acquisition, more especially as it is very free-flowering. Among other plants from the same firm were *Abies Alcoquiana* from Fusi-Yama, or the Sacred Mountain of Japan; a hardy and beautiful *Gymnogramma*; *Acrophorus alpinus*, a very handsome species with shining light green fronds; *Asplenium consimile*, a new hardy Fern from Chili; *Drynaria Hillii*; *Alsophila Tenitis denticulata*, with handsome shining fronds; and *Ligularia Kamperii* argentea, with roundish leaves variegated with cream colour. Besides these there were *Spharogyne latifolia*, *Retinosporas*, *Sciadopitys*, *Miconia pulverulenta*, and others noticed in previous reports.

From Mr. Bull came *Phaseolus lilacinus* with ornamental lilac flowers, the fine *Araucaria Rulei* from New Caledonia, together with one of its cones measuring about 20 inches in length; *Latania Verschaffeltii*, a variegated *Broussonetia papyrifera*, *Euterpe edulis*, *Areca dealbata*, the fine golden *Gymnogramma Laucheana*, and, what was very remarkable, a fine plant of the Madagascar *Ouvirandra fenestralis* in flower.

Messrs. Backhouse, of York, had a collection of rare Hymenophyllums and Trichomanes, among which were included *Trichomanes scandens*, Zollingeri, and megahanacum; also *Hymenophyllum valvatum*, *Lindsaea stricta*, and other tropical Ferns.

Messrs. E. G. Henderson & Son brought *Isantophyllum cyrtanthæiflorum*, with ornamental red flowers, not, however, nearly approaching those of miniatum in size; Mr. Watson, gardener to C. Leach, Esq., Clapham Park, contributed *Disa grandiflora superba*, with flowers in which a bright scarlet was the prevailing colour; and the Rev. J. G. Russell, of Frome, a fine seedling *Gymnogramma* with the fronds densely covered with rich yellow dust.

Mr. Standish had *Asplenium elegantulum*, a handsome Lycopod from Japan, and two Oaks from the same country, in one of which the foliage was very curious, appearing as if it had been in great measure gnawed away by some insect; this characteristic, however, being natural to the variety. A large and very interesting collection of *Faryas*, *Osmathus*, *Retinosporas*, *Aucubas*, and other Japanese plants was likewise shown by the same exhibitor.

MISCELLANEOUS.—An exceedingly interesting exhibition was contributed in this class by Lady Dorothy Nevill, to whom we owe the introduction of the *Ailanthus* silkworm into this country. Her ladyship not only showed the insect in all its stages from the egg to the moth, as well as the silk with which the cocoons are surrounded, but the worms themselves at work on the *Ailanthus* tree. The important feature of this exhibition was marked by the first prize being awarded to it.

From Messrs. E. G. Henderson came a collection of variegated Geraniums, including several of the new tricolor varieties, one of them called Lucy Grieve having a fine crimson zone deepening in the older leaves to a purplish-crimson; variegated Chinese Primrises, the beautiful silvery-leaved *Centaurea argentea*, and an extensive and very interesting collection of Ivies were also shown by the same exhibitors. Mr. Lavey and Mr. Higgs had some very fine pans of Lycopods; Mr. Lavey also sent a collection of ninety-six kinds of wall flowers, and Messrs. Rogers & Co. had a similar exhibit, as well as a number of which they exhibited fifty kinds, also Pinks and Pansies. Several good stands of the last two flowers were shown by Mr. Bragg, of

Slough, and Hooper, of Bath, both of whom had also Sweet William's; those from Mr. Bragg being Hunt's varieties, and exhibiting a great advance in roundness of outline. Mr. Turner had also a fine stand of Pinks as well as of Verbenas, for both of which he received prizes. Geraniums and Petunias were shown by Mr. Bull; a fine box of Iris variegata by Mr. Standish; and Fuchsia Pillar of Gold with yellow variegated leaves by Messrs. F. & A. Smith.

For Wardian cases arranged for the drawing-room, Messrs. A. Henderson & Co. had first prize for a large curvilinear-roofed one opening at the ends; and Messrs. Barr & Sugden had a small neatly-filled case of a much less expensive character. Some tastefully-filled flower-baskets were shown by Messrs. Henderson; and Mr. Macintosh, of Hammersmith, had three handsome window-boxes arranged with excellent taste; Pelargoniums, Calceolarias, Verbenas, and Stocks, with Mignonne and blue and white Campanulas in front, being the materials with which they were filled. They well deserved the first prize which they received.

An extremely ornamental jardinière from Mr. March, of St. James's Street, of which the accompanying is a representation, also excited great admiration. It consists of crystal, the stems being a series of spheres, the play of light through which has a most brilliant effect; while the glass itself is protected from breakage by a light framework of white metal. These jardinières are intended for the window-spaces in drawing-rooms or for placing on tables, their ornamental appearance being enhanced if elevated on blocks covered with maroon velvet.

FRUIT.

The display of Fruit was excellent, especially as regards Grapes, and Peaches and Nectarines; but, as we have already

remarked, its very existence appeared to be unknown to a great proportion of the visitors.

In collections the first prize was awarded to Mr. Turner, of Slough, who had fine Muscat and Black Hamburg Grapes, very fine Noblesse Peaches, Hunt's Tawny Nectarines, Black Tartarian Cherries, Marquis of Ailsa Melon, a Queen Pine, and President Strawberry. Mr. Penny, of Regent's Park, was second with a good Ripley Queen, a Green-fleshed Melon, Muscat of Alexandria, and Snow's Muscat Hamburg Grapes, Elrige Nectarine, Grosse Mignonne Peach, and Bigarreau Cherries. Mr. Henderson, of Trentham, was third; and an extra prize was given to Mr. Turnbull, of Blenheim.

PINES.—These were not numerous, no more than thirty Queens being shown, and only two Providences, both of which, though of large size, could not be considered as perfect; the one which received the first prize, from Mr. Young, of Aberaman, being over-ripe, and the other from Mr. Wallis, gardener to J. Dixon, Esq., of Congleton, being almost green at the top.

The first-prize Queen came from Mr. Grant, of Finchley, and was a handsome fruit, weighing 4 lbs. 9 ozs.; next came Mr. Smith, gardener to J. Walker, Esq., Calderstone, with one weighing 5½ lbs., but not ripe enough; and the third prize was given to Mr. Ward, of Headington, Oxford, for a well-ripened fruit of 4 lbs. 4½ ozs. Extra prizes were awarded to Mr. Smith, of Norwood, and Mr. Carr, of Byfleet; and good fruit were also exhibited by Messrs. Moore, Brown, Hannan, and Hall, the latter exhibiting, but not for competition, a very fine one of 4 lbs. 11 ozs., and another of 5 lbs. Of other varieties, an Enville of 8½ lbs. from Mr. Hall received a first prize, and a Black Prince from Mr. Dwerrihouse, of Heckfield, the second; a large fruit, but not ripe enough, coming from Mr. Young, of Aberaman.

GRAPES afforded the most extensive display, and the exhibitions of the Hamburg varieties by Mr. Meredith, and of the Black Prince from Mr. Hill, of Keele Hall, could scarcely have been surpassed.

In collections Mr. Hill had first prize for a fine one, consisting of Black Prince, Buckland Sweetwater, West's St. Peter's, Lady Downe's, Frankenthal, Black Hamburg, Early Saumur Frontignan, and Royal Muscadine. Mr. Henderson was second with West's St. Peter's, Pope's Hamburg, Mill Hill Hamburg, Frankenthal, Black Hamburg, Black Prince, Trentham Black, Victoria Hamburg, Golden Hamburg, Gromier du Cantal, Muscat of Alexandria, Muscat Hâtive de Saumur, Muscat Escholata, Muscat Hamburg, and Buckland Sweetwater. Mr. Cross, gardener to Lord Ashburton, Alresford, was third.

Of Black Hamburgs by far the finest were those from Mr. Meredith, the bunches being of gigantic size, compact, and perfect in colour and bloom; they were accompanied by some leaves of enormous size. Mr. Wallis, of Congleton, and Mr. Allen, gardener, to J. B. Glegg, Esq., of Withington Hall, received the second and third prizes, having also excellent bunches; but Mr. Meredith's threw all the others completely into the shade. Mr. Hannan, gardener to R. Crawshaw, Esq., Merthyr Tydvil, had also three fine bunches weighing 7½ lbs.

With Dutch Hamburg Mr. Meredith was also successful in taking the first prize with large bunches and berries, Mr. Widdowson being second, and Mr. Turner third; those from the latter were too red.

For Frankenthal Mr. Meredith was again first with splendid bunches both as regards size, form, and colour; Mr. Jones, of Cheadle, being second, and Mr. Henderson, of Trentham, third, both of the last two exhibitions being also good.

With Black Prince Mr. Hill left all other competitors far behind, showing the same magnificent bunches which he had at the Regent's Park, and the weight of which was 9 lbs. 5 ozs., and the length of the largest of the three about 20 inches. Mr. Cross was second with the same kind.

In Muscats of Alexandria Mr. Embury had first prize for fine bunches, the ripest shown, whilst Mr. Turner was second and Mr. Turnbull third, the bunches and berries being large but not so well ripened.

In other kinds of Muscats Mr. McPherson, of Radbourne Hall, Derby, took a first prize for large and finely-ripened bunches of the Canon Hall Muscat; Mr. Embury was

second for the same variety, and Mr. Turnbull third for fine bunches of Bowood Muscat.

In other white kinds Mr. Mould, Hartsbourne Manor, Watford, had the first prize for Chasselas Musqué, Mr. Hill second for three splendid bunches of Buckland Sweetwater weighing 6 lbs., and Mr. Henderson third for the same kind. Mr. Meredith had good bunches of Golden Hamburgh; and Mr. Cramb, of Tortworth, some of the finest which we have seen of the same kind, but unfortunately they were rubbed.

PEACHES AND NECTARINES.—The exhibitions of these were numerous, and, with few exceptions, the fruit large and well ripened. The best two dishes came from Mr. Dawson, and consisted of *Violette Hâtive* and *Chancellor*; the next best were *Violette Hâtive* and *Grosse Mignonne* from Mr. Young, of Havant. A single dish of *Royal George* from Mr. Lawkins, gardener to G. Brassey, Esq., Bramfield, gained first prize, the fruit being of the largest size; and a similar award was made to Mr. Wills, of Oulton Park, for the same variety equally fine, and it was also exhibited in great perfection by Mr. Edward, of Eyewood, who gained the second prize.

Mr. Cross, gardener to Lord Ashburton, had *Ehrage* and *Pitmaston Orange* Nectarines ripened to perfection, as evidenced by their depth of colouring, and received the first prize in the class for two dishes; and the second was taken by Mr. Tegg, gardener to W. H. Goschen, Esq., Roehampton, for very fine fruit of the same varieties.

In single dishes Mr. Wills had the first prize for *Ehrage*, large and finely ripened; but the fruit being placed on the leaves of *Cissus* discoloured we thought no improvement. Mr. Bannerman, gardener to Lord Bagot at Blithfield, was second with the same kind; Mr. Tillery third with *Red Roman*.

FIGS.—There were few exhibitions of these, the *Brown Turkey* being, so far as we remember, the only kind shown. Those from Mr. Smith, of Syon, and Mr. Pottle, were perfectly ripe and excellent; and good fruit also came from Mr. Robinson, gardener to R. Benyon, Esq., Englefield, and Mr. Henderson, of Trentham.

CHERRIES AND PLUMS.—There was a great lack of competition in these fruits. A fine dish of *Circassian* or *Black Tartarian* Cherries, from Mr. Turner, had the first prize; *Elton* from Mr. Widdowson, and *Black Eagle* from Mr. Beck of Tetworth, having the second and third. A good dish of *Black Tartarian* was also shown by Mr. Thomson, of Stanstead Park. The only exhibition of *Plums* was *Jefferson's*, from Mr. Ingram, of Reading.

STRAWBERRIES.—The best four dishes came from Mr. Lydiard, of Batheaston; it consisted of *Victory* of Bath, *Gem of the West*, and *Sir Charles Napier*, and *Oscar*, both very large. Mr. Turner was second with the two last-named varieties, *President* and *Empress Eugénie*. In collections of not less than six kinds, Mr. Widdowson had first prize for remarkably fine dishes of *British Queen*, *Prince of Wales*, *Crimson Queen*, *Sir C. Napier*, *Admiral Dundas*, *Sir C. Campbell*, *Oscar*, *Sir Harry*, *Prince of Wales*, *Myatt's Surprise*, and *Empress Eugénie*. Mr. Turner was second with a collection of twenty-eight sorts, comprising most of the above, *President*, *Rifeman*, *Carolina superba*, and some others.

MELONS.—Mr. Pottle had first-prize in the *Green-fleshed* class. Mr. Turner second in the same for *Marquis of Ailsa*. Mr. Tegg, gardener to Baron Hambro', third, for *King's Green-fleshed*, and first for a *Hybrid Scarlet*; *Scarlet Gem* from Mr. Tillery; and Mr. W. Tegg took the second and third prizes. Melons at present are wholly judged by flavour, and it is not uncommon to see the smallest and least attractive-looking fruit gain the highest prize; but whilst we quite agree that flavour should principally guide the decision of the Judges, we still think that appearance should receive some consideration, and that it would be desirable to institute a class in which flavour and appearance combined might be the test of merit, flavour counting, say, for two points, and appearance for one point.

MISCELLANEOUS.—Some fine orchard-house trees in pots were shown by Messrs. Lane & Son, and Mr. Cattermole, of Tooting Common, both of whom received first prizes; also, from the Society's Garden at Chiswick, and Mr. Kaile, of East Horsley Towers, who had *Plums* and *Peaches*; the other collections consisting of *Apples*, *Pears*, *Plums*, *Cherries*,

Figs, and *Peaches*. Some well-ripened *Tomatoes* were exhibited by Mr. Terry, the Hyde, St. Albans; a seedling *Melon* called *Monarch*, and weighing 10 lbs. 11 ozs., by Mr. Henderson, of Trentham; some excellent *Strawberries* by Mr. Marcham; *Laxton's Early Prolific Pea*, which turned out to be nothing but *Dickson's Favourite*; and some seedlings, an account of which will be found in the proceedings of the Fruit Committee.

THE NATIONAL ROSE SHOW.

I COULD quite understand, when I saw the Exhibition to-day, why it was that the Rose Show had been tacked on to the third great Exhibition. Retrenchment, I presume, was the order of the day. No prizes for *Orchids*, nor—as it has, I know, been suggested by one of the most active members—*Zonale Geraniums*; none either for show *Geraniums*, which were shown so well at the Regent's Park last Wednesday; and hence one mass of green, very refreshing no doubt, filled the nave, fine-foliated plants and *Ferns* forming the great bulk of the things sent. And had it not been for the *Roses* the Show would have been poor indeed; while the *Fruit*, separated far from the others, lent neither its fragrance nor its beauty to the great body of the Exhibition. Why it could not have been arranged in one of the contiguous courts I could not understand.

My business is, however, with the *Roses*, ever beautiful and charming as they are. I feel compelled to say that, on the whole, *Roses* have not been shown in first-rate condition this season. Neither at the Crystal Palace nor to-day had they that freshness and contour which one likes to see them always possess, too many open eyes and battered faces suggesting ideas of late hours and an over-supply of moisture. Some exquisite blooms were, no doubt, exhibited; but I am speaking of them as a whole. As far as to-day's Show was concerned, the *Amateurs* were decidedly in the first rank, and Mr. Hedge, as usual, in the first rank of *Amateurs*. Some of his flowers were very exquisite. He has an immense stock; and, with his thorough knowledge and skill, he has advantages which make it a difficult matter to vanquish him.

The new *Roses* were as usual those most eagerly looked after; and it is only another instance of the uncertainty that hangs about *Rose-growing* that the same flower in different boxes bore a totally different character, and would hardly have been recognised as the same variety. After a careful scrutiny of the various stands, and the new *Roses* generally, I think that we may set down Mr. Standish's *André Leroy*, Mr. Geo. Paul's *Lord Canning*, and *Le Rhone* (*Guillot fils*), as the three best new *Roses*. The first is a seedling reared by *Trouillard* of Angers, and named after his employer, M. Leroy. It was figured in the *Florist and Pomologist*; its shape and contour were well given, but the colouring fell very far short of the reality. It is a thick, fine-petalled flower, of excellent shape, and of a rich dark velvety crimson, and of good habit. *Lord Canning* is a flower somewhat of the build of *Comte de Nanteuil*—a bright pink with large petal. *Le Rhone* is very much of the style of *Senateur Vaisse*, with a dark shading in it.

While on the subject of new *Roses* I may mention that I received a few days ago from my friend, M. Margottin, of *Bourg-la-Reine*, a box containing blooms of two new flowers he purposes sending out this autumn: one is a splendid flower, a seedling of *Louise Odier*, crossed with a dark *Hybrid Perpetual*, having the exquisite shape of its parent, and retaining (in a *Bourbon*, a great object), a delicious fragrance—one or two petals in a letter quite perfumed it. It is of excellent habit, as I saw when in the raiser's garden. The colour is a deep crimson. I feel persuaded that this will be a great acquisition.

I now proceed to the stands of new *Roses*. The first prize was awarded to Mr. W. Paul for the following:—*Maurice Bernardin*; *Robert Fortune*, very globular; *Prince Camille de Rohan*, very dark and fine; *Charles Lefebvre*, good; *Professor Koch*, dark and double; *Louise Darzins*; *Louise Margottin* (1863), pretty and good; *Beauty of Waltham*, good; *Turenne*; *Gloire de Chatillon*, like *Madame Masson*; *Vicomte Vigier*, good; *La Brillante*, very fine; *Mademoiselle Emain*; *François Lacharme*, excellent; *John Hopper*, good; *Madame Ernest Dreol*; and *Madame Charles Weid*.

Mr. B. R. Cant was second with *Souvenir de Comte Cavour*; Baron Adolphe de Rothschild, good; Olivier Delhomme; François Lacharme; Vicomte Vigier; Vulcaïn; Charles Lefebvre; Reynolds Hole, a good pink; Monte Christo, dark; Madame Charles Wood; John Waterer; La Brillante; excellent; Madame Ernest Druot; Grégoire Bourdillon; *Souvenir de Mons. Rousseau*; Wilhelm Pfitzer, dark; and Madame Boutin, fine.

Messrs. Paul & Son were third with *President Lincoln*, a promising flower; Le Baron Rothschild; Prince Camille de Rohan, very fine bloom; Lord Clyde, good; Madame Caillat; Le Rhone, good, dark; Lord Canning, a fine new English Rose of Messrs. Pauls' raising; Monte Christo; Gloire de Bordeaux; Olivier Delhomme, very good; Belle de Printemps, curiously mottled, but bad shape; Baron de Rothschild; Wilhelm Pfitzer; Louise Darzins; *Souvenir de Comte Cavour*; Paul Despard; and Princesse d'Orléans.

Mr. Standish, of Bagshot, had Grégoire Bourdillon, *Souvenir de Comte Cavour*, Madame Standish, Charles Lefebvre, Madame Boutin, Vicomte Vigier, Madame Charles Wood, Mrs. Dombain, Marguerite Appert, Maréchal Vaillant, André Desportes, John Standish (a good bloom), André Leroy (fine), Catherine Guillot, J. E. Lombard, Reynolds Hole, Vulcaïn, and Alexandre Dumas.

In Mr. Keynes' stand were *Souvenir de Comte Cavour*, Gloire de Bordeaux, François Lacharme, Robert Fortune, Monte Christo, André Desportes, Marguerite Appert, Paul Despard, Maréchal Vaillant, Charles Lefebvre, Tarcène, Mlle. Julie Duran, John Standish (very good), Le Brillante, Alphonse Damazin (good), Richard Smith, Madame C. Wood, and Olivier Delhomme.

Mr. Crauston had La Brillante, Madame Caillat, Camille de Rohan, Comte Cavour, Wilhelm Pfitzer, Murillo, Le Rhone, Richard Smith, Alphonse Damazin, Belle de Massifs, Alfred de Rongemont, Archevêque de Paris, L'Esmeralda, Duc de Bassano, *Souvenir de M. Rousseau*, Comte de Courcy, Vulcaïn, and Lecrosnier.

Amongst the Roses there of last season, there are evidently some which are destined long to remain in our catalogues. Such flowers as *Souvenir de Comte Cavour*, Prince Camille de Rohan, Maréchal Vaillant, Madame Boutin, Madame Charles Wood, Alphonse Damazin, Adolphe Nodet, Charles Lefebvre, and François Lacharme are indispensable; while Wilhelm Pfitzer, *Souvenir de Lady Eardley*, and Vicomte Vigier stand well nigh equal to them if not quite. Thus a dozen good Roses may safely be set down as the production of 1861. If there is a defect, it is that as a rule they are not quite full enough, and thus apt at times to open too much. Madame Charles Wood is the most extraordinary flower for lasting that I know. I have had blooms of it cut for a week without falling, while La Brillante has just the opposite tendency: the colour flies very soon. Of them all I should from present appearances be inclined to fix on François Lacharme as the best of the lot.

I had intended to have given this week the details of the prizes in the other classes, but must reserve it for the next issue.—D., Deal.

BHOTAN RHODODENDRON AT REDLEAF.

Your impression of the 23rd of June has only just come to hand, or I would sooner have replied to the courteous request of "A DEVONIAN," to say that the Bhotan Rhododendron alluded to expanded the first bloom on the 20th inst., and the last on the 28th, thus coming unfortunately between two meetings of the Floral Committee, to whom I had intended to submit it.

I think it is likely to prove identical with the one described by your correspondent, as it is a large trumpet-shaped flower, pure white, with an orange throat, and a most agreeable and delicate fragrance. Each bud produced three blooms.

With regard to its hardness, I cannot speak with the necessary certainty, our plant having never been subjected to the open air in the winter; but at that season it had only the protection of a small lean-to, and was never covered. Judging from appearance, I should say that it is quite as hardy as the Sikkim varieties I mentioned before.

Where it can be purchased I cannot say. This plant was

presented to my employer by a lady in Scotland, and labelled "Rhodo from Bhotan." Perhaps these notices may elicit some information on that subject.

This has been a very fine season for the Sikkim Rhododendrons out of doors, and they have made a remarkably clean and handsome growth, owing to the absence of those piercing morning frosts in April and May.—JOHN COX, Redleaf.

PROPAGATION BY EYES.

THE facility with which certain plants are reproduced from buds or eyes induces me to give a short detail of my experience in this mode of propagation, laying no claim to originality, but simply to aid those who may not have practised it.

VINE EYES.—To propagate the Vine by the means of eyes, procure a sufficiency of the wood of last year's growth—that which is removed by pruning, selecting the medium-sized well-ripened wood. Commence with the bottom eye; holding the shoot perpendicularly in its natural position, and having the eye turned from you, place the blade of the knife some quarter of an inch beneath the eye, drawing the knife cleanly through in a slanting downward direction. Next turn the whole branch directly upside down, cutting the eye clean away from the same by drawing the knife cleanly through the wood—in its present position closely beneath it—also in a partially slanting direction. When finished the eye should in form somewhat resemble

fig. 1.

Fig. 1.

Having the eyes thus properly prepared, proceed to pot or pan them. I am partial to the latter, as when moderately shallow I can the more readily command an evenness of temperature, whether the heating materials be too hot or slightly the reverse, as, by simply plunging the pans in the latter case, or placing them upon the surface of the material in the former, I can readily command the desired heat. But whether pots or pans be chosen take care to crock them well, as an excess of moisture around the eyes is most injurious to these.

The soil I use is formed of two parts good yellow loam, one of peat, the same of leaf mould, with sand in quantity sufficient to make it nicely porous. I sift it, because by doing so I am enabled better to divide the roots of the plants than if the soil were rough. Having the pots filled, press firmly each eye in the soil about 2 inches apart, taking care not to have the eye buried beneath the soil, though no part of the wood should be visible. If the eye be not fully exposed, it is liable to damp or rot off, even after it has made a start to grow.

Give gentle bottom heat, say 50°, increasing 5° weekly until the maximum of 70° is attained. Care should be taken to keep the heat, both above and below, at a moderate temperature, for an excess of heat often causes the eyes to start prematurely, and before the wounds have rooted, or even formed the callus.

After the first fortnight or so, when it may be supposed the callus is formed or that they have made good progress, an advance of heat with a nice growing atmosphere will be beneficial to them, continuing thus until they have made reasonable growth and you surmise they are getting in size too large to remain advantageously together in the same pan, with a view to their being readily parted for the purpose of potting-off singly. Then small-sized pots having one substantial crock in the bottom, good yellow loam, and well-decomposed dung, &c., will suit them well, and into this they should be carefully potted.

THE ORANGE, CITRON, and CAMELLIA may be thus propagated. About the first week in March pick out a well-ripened shoot, the growth of the last or preceding year. From this with a sharp knife simply cut out the leaf and eye, having at their base a small portion of the wood, just sufficient to give it the appearance of a cutting having a small heel to it. Procure good loam, peat, and decomposed cowdung in equal parts, with a fair proportion of silver

sand, and into this they should be firmly planted, in pots or otherwise, to be placed upon a gentle hotbed, giving an advance of heat eventually, as I have already explained with reference to the Vine.

THE HOLLYHOCK.—An essential point is procuring medium-sized well-ripened wood having little central pith. I mark a few stalks some days before requiring them, pinching the point off from each, which causes the buds to become slightly active and prominent. I then—having the whole stalk divided into three or four pieces, to admit of its being more readily handled—cut out the eyes, commencing with the lowermost ones, cutting the entire bud, leaf, &c., away from the stem an inch or more above it, severing it clean across. Then finish off the base at the joint and base of the leaf precisely as all cuttings are made, taking care, however, not to cut too closely, or to loosen the leaf or otherwise injure it during the process of manipulation.

Use a compost of one part of good yellow loam, one of leaf mould, and one of sand. Place six or eight eyes in a 48-pot, keeping the leaves up where necessary by a support. At first a gentle heat should be given, to be advanced eventually as explained above; though where no heat happens to be at command they often root well plunged in sawdust, packed in a frame or box placed in a shady situation and turned northward. They should when rooted be properly potted-off, &c.

THE ROSE.—To propagate the Rose by this means, procure shoots similar to those from which eyes would be taken in the process of budding. Simply cut the wood directly across about half an inch above and below the leaf, eye, &c. Plant in soil, and adopt the treatment recommended for the Hollyhock.

THE DRACENA is easily propagated by cutting in pieces the leafless portion of the upright stalk, though I believe of our fellow labourers few would like to destroy a good plant in the process. My real object, however, in introducing this genus is to refer those who have a plant to the very base of its main stalk, where will be found small growths having an appearance not unlike the main eyes of a Jerusalem Artichoke. At times two or three of these are seen attached to each other. They should be cut apart, and placed in free sandy soil in a good brisk top and bottom heat, when they will be seen to shoot up readily, each forming a plant. Under this process the best variegated kinds appear to lose their chief merit, at first assuming the uniform colour of the original species, though they become beautifully variegated the second season.

ALOCASIA METALLICA.—We give the mode, which is the simplest possible. Just suppose the metallic-looking Alocasia to be a *Richardia ethiopica*. Reduce this to a small plant and cut the bottom of the plant away, dividing it into as many little pieces as you can perceive eyes in the same, leaving where practicable the small roots or rootlets found attached to each, potting, plunging in heat, &c. But let those who are not quite so venturesome simply take the soil away carefully from the base of the main portion of the plant, cut a reasonable bit off and pot it, carefully repotting the plant, thus proceeding as the plant continues to grow, and soon a good stock will be their reward.—W. EARLEY, *Digswell*.

CHIEF GARDENS OF GREAT BRITAIN.

WE have so repeatedly been asked for a list of gardens having attractions worthy of a visit at the cost of some expenditure of money and time, that we have determined to make a commencement, and to ask of our readers to furnish us with similar lists. The sooner they favour us with them the more useful will they prove, as the season for seeing such gardens in their gayest array is at hand.

We have been asked also to state where and what fee should be paid for the pleasure thus afforded, and for the time of the gardener devoted to the visitor; but upon this point we can give no information. The practice varies so much that no rule can be stated as generally applicable. A gardener visiting such establishments should pay nothing under any circumstances, and the feelings of all other parties we think might be considered, if at all such gardens a book was kept in which visitors must inscribe their names, and on the table by the side of that book were copies of a pam-

phlet, with a plan of the garden, and a short description, price 3s.

The gentleman who has favoured us with the following list adds as a note:—"Those named are all first-class. Many others well worth visiting might have been included, but I have kept the list select."

PRINCIPAL GARDENS IN NORTHUMBERLAND.

Name of Residence.	Proprietor.	Gardener.	Nearest Railway Station.
Alnwick	Duke of Northumberland...	Mr. Bailey.....	Alnwick.
Arcoat	H. Shum Storey, Esq.	Mr. Elsworth	Killingworth.
Belsay	Sir Charles Monck, Bart.	Mr. Jackson	Newcastle.
Beaufort	Wm. Cutbush, Esq.	(Unknown)	Corbridge.
		Mr. Forsyth (Flower Depart.)	
Creswell	A. Creswell, Esq.	Mr. Robson (Fruit Depart.)	Longhirst.
Felton Park ...	Thos. Riddell, Esq.	Mr. Crossley	Acklington.
High Gosforth	Eustace South, Esq.	Mr. Jno. Hall	Killingworth.
Malvern Hall...	Edward James, Esq.	Mr. Geo. Cook	Wylam.
Meldon Park...	John Cookson, Esq.	Mr. C. Graham	Meldon.
Mitford	Mrs. Mitford	Mr. Jas. Taylor	Morpeth.
Newton Hall...	Mrs. Widdington	Mr. Davison	Alnwick.
Sandhoe	Rowland Errington, Esq.	Mr. Marshall	Corbridge.
Wallington ...	Sir Walter Trevelyan, Bart.	Mr. Hedley	Meldon.
Wolsington ...	Matthew Bell, Esq.	Mr. W. Lawson	Killingworth.

A FEW OF THE BEST GARDENS IN DURHAM.

Lambton	Earl of Durham	Mr. Stephenson	Fencehouses.
Gibside	Rt. Hon. Wm. Hutt	Mr. Scutt	Scotswood.
Ravensworth ..	Lord Ravensworth	Mr. Moulton	Newcastle.
Raby	Duke of Cleveland	Mr. Short	Barnard Castle
			or Winstan.
Southend	Joseph Pease, Esq.	Mr. Richardson	Darlington.

These gardens may be visited any day by applying to the gardener.

ROYAL HORTICULTURAL SOCIETY.—JULY 1.

FLORAL COMMITTEE.—The entries of florists' flowers on this occasion were very limited, and of no particular interest. The new plants were numerous, and chiefly from Messrs. Veitch, of Chelsea. The names and awards made to the new plants will be given in our next Number, our memoranda not being at this moment before us.

Mr. Turner, of Slough, sent two seedling Pinks—one named Rev. George Jeans, a heavy-edged rosy crimson flower, with well-arranged petals, was awarded a first-class certificate. The other seedling was not considered any advance on other varieties in cultivation.

Mr. Francis, of Hertford, exhibited a very dwarf-habited Scarlet Pelargonium with remarkably small green foliage, the trusses of flowers not very bright nor of good form. The plant was commended as useful for decorative purposes.

Messrs. E. G. Henderson exhibited their superb collection of Variegated Zonale Pelargoniums, which for richness and brilliancy of colouring are unequalled. Mrs. Pollock and Sunset, so well known to the floral world, received first-class certificates in 1861. Lucy Grieve and Italia Unita were on this occasion awarded first-class certificates. Lucy Grieve is after the style of Mrs. Pollock, but with variously-tinted zones of brighter colours, and the plant is of more robust habit. Italia Unita is a very brilliant white-foliaged variety. The shaded zones of dark crimson make it very conspicuous and distinct.

Mr. Bull sent several seedling Zonale Pelargoniums. One, named the Clipper, was a scarlet flower of excellent form, which was requested to be shown again, the specimens sent not being in condition.

With the exception of a stand of seedling Pansies, which at this late season were out of character, and a seedling Rose which was very far behind the Roses of the present day, there were no other flowers worthy of notice.

FRUIT COMMITTEE.—There were a few subjects before the Sub-Committee of the Fruit Committee at the last great Show, consisting principally of seedlings.

Mr. Turner, of Slough, again sent his seedling Strawberry President. On this occasion it was much larger than it has ever been exhibited previously, and is certainly a fine-looking fruit. The flavour, however, did not come up to the standard of what the Committee thought first-rate; but they were, nevertheless, of opinion, that on account of its size and solid flesh it would be a good market variety.

Mr. Lydiard, of Bathaston, near Bath, also sent two seedling Strawberries, both of which were fine-looking fruit. Gem of the West is a fine bright scarlet colour, with a good deal of the Pine flavour in it, but it lacks sugar. This deficiency may, however, be attributable to the season. Victory of Bath is a large darker-coloured variety, and its flavour was not remarkable.

Mr. Ruffet, gardener to Lord Palmerston, Brockel Hall, sent a seedling Strawberry called The Premier, which, judging from the plant exhibited in a pot, bears immensely. The fruit is large, dark-coloured, and the flavour is very good.

Mr. Tillery, of Welbeck, sent a seedling Nectarine raised from the Elruge. It is of medium size, and in colour closely resembles its parent, but the flesh is rather more stained next the stone than in the old variety. It is a good sort, but scarcely sufficiently distinct.

Mr. Archibald Fowler, gardener to Lord Dalhousie, Castle Kennedy, Stranraer, N.B., sent fruit of a very large Fig, which weighed 6 ozs. It was received without a name, and the variety has been grown at Castle Kennedy for about a century. It appears to be the Large White Genoa. It is of turbinate shape, pale greenish-yellow colour, with a brownish tinge on the apex of the fruit; the flesh brownish-red and of good flavour, but not first-rate.

Mr. Keynes, of Salisbury, exhibited bunches of a Grape introduced from Corfu. They were very large and shouldered, the berries of good size, well set, and of a somewhat ovate shape, green, and with a transparent skin showing the texture of the flesh through it. It was not sufficiently ripened for a correct judgment to be formed of its qualities.

Mr. J. Fleming, gardener to Her Grace the Duchess of Sutherland, at Clevedon, sent a seedling Grape raised from a cross between White Frontignan and Royal Muscadine. It combined the properties of both parents; but as the plant is yet young and the bunch was hardly ripe, it was not in condition to form a correct opinion of its merits.

Mr. Rivers, of Sawbridgeworth, exhibited a seedling Early White Nectarine raised from Victoria Peach; the flavour of which was piquant and gave evidence of being improved by being more highly ripened. He also had an Early Orange Nectarine a fortnight earlier than Pimaster Orange and with the same flavour; and a seedling Hantbois considerably larger than the Prolific. It is called the Royal Hantbois, bears abundantly, and is a great improvement on the old variety if its flavour is produced equally good.

Mr. Laxton, of Stamford, exhibited two dishes of his seedling Early Prolific Pea, which proved to be Dickson's Favourite. In another dish, Mr. Laxton exhibited a small frame variety as Dickson's Favourite, which he is evidently growing in error for the true sort.

THE MELODY AND HARMONY OF COLOURS.

According to the commonly-adopted doctrine, there are three primary colours, red, yellow, and blue. The combination of these in certain proportions yields white. The absence of them all is black. These primaries, mixed together two and two, produce what are called secondary colours—viz., orange, from the mixture of red and yellow; green, from the mixture of yellow and blue; and purple, from the mixture of red and blue. From the combination of the secondaries arise three tertiary colours—citron, from the mixture of orange and green; olive, from the mixture of green and purple; and russet, from the mixture of orange and purple.

The language of music has been applied to colours, and colourists talk of the melody of colours, and the harmony of colours. Colours are said to be in melody when two contiguous tints, or shades, or hues, run insensibly into each other—as when red slides into pink and white, and purple deepens into dark purple, or merges into red-purple and red. Two different colours are said to be in harmony when their association is felt to be pleasant to the eye.

Two colours are said to be complementary when they together make up the white beam. Thus green and red are complementary, as also purple and yellow, orange and blue. The eye feels pleasure in seeing colours in melody, or melting into each other. It also feels a pleasure in contemplating certain associations of different colours. In parti-

cular the eye is pleased when complementary colours are beside each other, or are under the view at the same time. Complementary colours contrast the one with the other, but are always in harmony. It is necessary to add that white associates pleasantly with every other colour; so does black.

The following diagram is constructed with a view of

showing what colours are complementary to each other. In the figure we have three primary colours—red, yellow, and blue; and the three secondaries, orange, green, and purple, with the hues of secondaries on either side. We have also the tertiaries, citron and russet. The diagram is so constructed that the colours in corresponding segments of opposite circles are complementary, and so in harmony. Thus—red and green, blue and orange, yellow and purple, are complementary colours. According to the hue of any particular secondary, so is also the hue of its complement. Thus a pure purple requires a yellow, but a red-purple requires a yellow-green, and a blue-purple a yellow orange, as the complementary colour; and so of all the other secondaries. The tertiary citron is in harmony with a dark purple, purple requires a yellow, but an olive a dark orange, and russet a dark green. These principles are taught now in every school of art, and are attended to in the manufacture of all our finer fabrics in which colour is an element of beauty, as in dresses, carpets, hangings, and furnishings of various descriptions.

Green Harmonising with Red and Russet.—The soft hue which the Author of nature has been pleased to give the leaf of the tree and herbage, is by far the most abundant colour in the vegetable kingdom. Now, wherever the flower of a plant is red, it associates agreeably with the leaf. The flowers of the Rose, and many Pinks, Geraniums, Pelargoniums, Mallows, Lychnises, and dozens of others, contrast strikingly with the foliage of the plants on which they grow. The eye delights to see the fruit of the Cherry, the Rose, and the Thorn, and the berry of the Holly, the Mountain Ash, and other plants peeping forth from the green leaves.

Purple Harmonising with Yellow and Citron.—This is the second most prevalent harmony in the vegetable kingdom. So far as we have been enabled to observe, purple of various tints, shades and hues, such as red-purple where there is a preponderance of red, and blue-purple where there is a preponderance of blue, is the most frequent colour of the petals of plants. In beautiful contrast, we often find yellow in the centre of the flower. Thus in the garden Polyanthus, and many varieties of Anemula, the outer rim of the corolla is purple, and an inner circle is yellow. Purple and citron are also commonly associated with the flowers of Grasses.

Orange Harmonising with Blue and Olive.—This harmony is less frequently met with in the vegetable kingdom. It is very common in the sky. A pure blue, however, is rarely to be met with in the flower in any of the organs of plants. Most of the flowers called blue have more or less a tinge of red. In the flower of the Forget-me-not, which ever greets the eye so cheerfully, there is a border of blue-purple, and a

centre or throat of orange-yellow. In the Pansy, so rich and soft, that it has obtained the name of "Heart's-case," we have yellow and purple of various hues and degrees of intensity, brightened by a mixture of white. In the Daisy, described as "crimson-tipped," by Burns, there is the yellow disk, harmonising both with the white ray and purple on its tips. These flowers are favourites with all classes, peer and peasant, old man and young maiden, countryman and townsman. They pleased us in our childhood, when we seized them, and sought possession of them so eagerly, but found them fading, like all earthly enjoyments.

The frequent juxtaposition of complementary colours must have a physical as well as a final cause. If it be asked, What this is? we are inclined to answer by asking another question, the answer to which may possibly throw a light upon the first. When a beam of light falls on a green leaf, the green is said to be reflected and the red absorbed; but we ask, What becomes of the red? When the beam falls on a purple petal, the purple is said to be reflected and the yellow

absorbed; but what becomes of the yellow? Are the red and yellow in these cases absolutely lost? If these constituents of the beam be lost, they are the only powers in nature which are. In this world of ours, nothing which has existed is lost; as nothing new absolutely comes into being. It is now a received doctrine, that the heat absorbed by plants, in the geological era of the coal measures, is laid up in fossil deposits, and may come forth in our epoch when the coal is ignited. May we not suppose, in like manner, that the red absorbed by the plant, when the green is reflected by its leaves, will come forth, sooner or later, in some form—in young stem, flower, or fruit; and that the yellow absorbed by the flower, when the purple is reflected, will come out in the yellow pollen, or in some other form? We have thought, at times, that as the pure white beam, when it reaches the earth with its atmosphere, is divided into several rays, and that no one of these is lost, and as they will come forth sooner or later, we have thus a harmony of colours in nature.—(*American Gardener's Monthly*.)

UROPEDIUM LINDENII.

If this is not the most brilliant, it is at least the most singular of terrestrial Orchids. For gardens it is a rare curiosity, for botanists a perfect wonder, and an object of just pride for the enterprising cultivator who introduced it. The characters of the type may be stated in a few words:—It is a *Cypripedium*, the labellum of which, instead of being formed like a slipper, extends in that of a tongue, becoming narrow and extending downwards, like the other divisions, in the form of a narrow band. The sepals are of a yellowish-white colour; the two inferior are joined together in one, about 2 inches long, and striated with greenish nerves. The petals (including the labellum), extend to at least a foot in length; they are pale, striated in face of their internal base, having a spot on the two posterior corners or horns of the depressed caruncle or protuberance which surmounts the gynostem or column.

This noble plant is a native of New Grenada, where Mr. Linden discovered it 1843, in the territory of Chiguara, in the small woods of the Savannah, which rise on the Cordilleras to an altitude of 1650 metres, or fully 5500 ft., and overlooking the vast forests of Maracaybo. It has been described by Dr. Lindley from a dried specimen; and was first flow-

ered for the first time in Europe, in the rich collection of M. Pescatore, at his Château, Celles, near St. Cloud.

It is worth while to consider for a moment one of the most curious examples of that law which is justly called the law of balance in the organs (of plants). According to a fundamental rule of symmetry in their flowers, Orchids should have a verticil of three stamens, alternating with the interior parts of their perianth. Now, in consequence of a normal abortion with the generality of these plants, the posterior stamen exists only in a state of fertility; the two lateral ones having disappeared, or being only present in a state of sterile protuberance on the gynostem or column. In the *Cypripediums* on the contrary (*Cypripedium*, *Uropedium*), the posterior anther is replaced by a fleshy caruncle, but to compensate for this, the two lateral anthers exist in a perfect state. If we add the one-stamened flower of an Orchid (*orchis*), to the two-stamened flower of the *Uropedium*, we obtain the three-stamened flower of the ideal and symmetrical type of the Orchid family; and thus, in botanical arithmetic, as in ordinary calculations, two added to one make three.—(DR. PLANCHON, *Flore des Serres*.)

MAKING A STRAWBERRY SOIL.

THE remarks made by my esteemed friend, Mr. Robson, at page 432, in reference to the repeated failures experienced by "A. Z.," induces me to bring to your notice a case in my own experience, where an apparently similar difficulty was successfully overcome. It occurred in the garden of a gentleman in my neighbourhood.

He was one day lamenting that he could not grow his most favourite fruit, Strawberries, in his garden, try what he would, and begged me to go over to advise him. I did so, and found the soil to be of the same light sandy nature as that described by your correspondent; and I have found from experience that such soils when highly manured do produce very fine foliage indeed, but very little fruit—in fact, they "run to straw," as a farmer would term it.

My advice was, to take off the top spit and supply its place with 9 inches of clay and strong loam, such as is used in making bricks, and incorporate it well with the subsoil. This was done, and nothing could be more gratifying than the success attending the operation, as the plants produced fine fruit in great abundance, and I was glad to hear that the example had been followed by several other persons in the immediate neighbourhood.—JOHN COX, *Bullong*.

WEIGHT OF MUSA CAVENDISHII FRUIT—ORIENTAL ORCHARD-HOUSE.

HAVING seen in your Journal two notices lately of the weight of heads of fruit of the *Musa Cavendishii* or Banana, they have stirred up old recollections about a head of the fruit I grew when I was a journeyman some ten years ago, and of a singular incident that happened concerning it, which fixed it upon my memory.

The said head weighed, when freed from all superfluous stem, 56 lbs., and numbered 220 or 222 pods of fruit. Knowing that the Banana is still grown extensively in the same place, I wrote to the gardener, and the following is an extract from his reply:—

"Coodham Gardens.

"Regarding the Banana, I think that I have a better fruit just now than either of those you mentioned. The number of swelled pods are 212, and which I think will weigh close on 50 lbs. I weighed a fruit last year which was 53 lbs. I expect this fruit to be ready towards the latter end of July, or the beginning of August.—E. A. STEWART."

Writing the above reminds me of an article written by me upon the cultivation of the *Musa* as a hothouse fruit for a certain gardening periodical, which was not inserted because, as the editor said, it was "not of general interest." Perhaps now that we have had a good deal of titling and firing of blank cartridge upon the orchard-house question, might it not be worth while to prefix the word "oriental," and try how they would succeed? A practical knowledge of the habits of such fruits would soon form an idea of what an "oriental orchard-house," should be, and the skill required in their cultivation would be about a minimum.—ALEXANDER STORRIE.

P.S.—I have grown various varieties, but the *Musa Cavendishii* is the best. *M. sapientum* grows taller, and has not such large heads of fruit.

DWARF SWEET PEA.—I lately sent a query asking why it is that a dwarf eatable Pea has been obtained, and that a dwarf Sweet Pea has not. Can botanists or florists assign a reason? At present neither have replied to it. Might not hybridising the dwarfest eatable Pea with the Sweet Pea, produce some change?—MATTHEW FITT.

EARLY CELERY.—The working men of Dewsbury have long been celebrated for the production of early Celery. Twenty years since it was considered very early if it was on the table at Dewsbury Feast (July 25), now it is not considered to be so unless it is dug up in June. Last year the earliest was dug up the last week in June, this year the first was on the table June 21st. The length of the best

stalk was 21 inches long, blanched 10 inches, and of a proportionate thickness. It was grown by a working man, William Clegg.—S.

THE GOOSEBERRY CATERPILLAR AND ITS HABITS.

NOTICING a remark made by your correspondent "R. F.," on the 2nd of June, in his "Doings of the Last Week," respecting the non-appearance of the gooseberry caterpillar and his attributing the disappearance to the agency of birds, I am induced to offer a few facts that have come under my own observation.

Like "R. F.," as soon as the trees were in full leaf and the weather genial, I commenced examining the trees to see if the caterpillars had made their appearance, and I found them in various stages of existence. Some appeared to be just issued from the egg, and had made many small holes through the leaf; in most instances each grub had eaten out a hole the size of a snail shot. Other caterpillars were more advanced, some being half and others three-fourths grown, and there were some that had apparently attained their full size. Amongst the latter there were a few of a pale green colour; and adhering to the leaf they were on, or close by, was the dark skin.

I then began to look for the parent insect or fly, but could discover nothing but a black fly, which was very numerous; and in most instances, upon the trees being touched or an attempt made to capture them, they fell to the ground and were lost. At first I began to think they might be the parents, and, if so, could see no means of saving the trees and crop but by catching and killing them. I consulted all the works I had on natural history, but could find no other information than that these caterpillars are the produce of a species of saw-fly, which deposits its egg on the leaf of the tree; the egg in course of time giving birth to a caterpillar; the caterpillar, after attaining its period of existence, falling down from the tree and burying itself in the earth till the following spring, then bursting from its crusty shell and seeking the young leaves to perform the like offices again. I therefore resolved to try some experiments upon them, and for that purpose I procured two full-grown caterpillars and placed them under a bell-glass on the 23rd of April.

After the caterpillars had changed their skins and fallen from the leaves on which they had been previously feeding, I began to examine the sand in the flower-pot to ascertain their whereabouts, and I found the one that changed first directly under the leaf from which it fell, buried about an inch from the surface. The other I unfortunately damaged with the point of a knife used to discover them, probably owing to its not having attained sufficient strength of shell. I then placed them on the top of the soil in a smaller flower-pot, covering them with a bell-glass as before simply for convenience.

On Saturday, May 16th, about eleven o'clock, I had the gratification of seeing a fly under the glass, which I was satisfied had come from one of the chrysalises. It was about one-third of an inch in length, the fore part of its body of a dirty yellow, and the tail of a bright yellow colour, with transparent wings very similar in appearance to the fly that is the cause of galls upon the Oak trees in many places.

At one o'clock I collected some more cuttings; and, after proceeding as in the former instance, I placed the fly under the bell-glass with them. The fly now seemed less restless than before, and began to walk about the leaves apparently with pleasure. After watching it for a few minutes I observed it walk to the under side of a leaf, and, after examining it for a short time, it walked to the top of the leaf and then commenced laying its eggs along the midrib in the direction from point to footstalk. The number of eggs deposited on the midrib was about twelve. Then the fly went to the four side-ribs of the leaf, and there deposited from eight to ten eggs on each rib, amounting in the aggregate to fifty-two. A number of eggs were laid on other leaves, but they were not so regularly placed. Their total numbers, I believe, were about 200. The eggs are of a transparent white colour, about one-sixteenth of an inch long, with a dark spot at one end, and they are deposited with great regularity about the same distance apart.

On Friday, May 22nd, I fancied there was a slight alteration in the colour of those eggs that were laid first, and about eleven o'clock on Saturday, 23rd, they were evidently producing caterpillars, for they could move about. After preparing a flower-pot by filling it with silver sand, &c., as if for choice cuttings, I selected three vigorous shoots from a healthy Gooseberry tree; and, after carefully inserting them, I introduced the two full-grown caterpillars, making them secure by putting a bell-glass over them and pressing the same into the sand to prevent their escape from the side. They soon began to eat greedily, and appeared quite at home, consuming at the rate of a full-grown leaf in twelve hours.

On the next day (the 24th) one began to appear torpid, and by the middle of the day had changed its skin, leaving it on the leaf it had been feeding from the previous day. From the size of the leaf that remained and the amount consumed by the other, I presume it had not eaten anything for the last twelve hours. By changing its skin it had assumed a pale green colour and remained in this state three or four hours, taking no more food, and then fell from its position and buried itself in the soil—which it does very quickly—and in about six or eight hours it was covered with a crusty shell.

The other caterpillar did not change its skin till the 28th, but the operations were the same; but I found it took about twelve hours from the time it changed its skin till it became a chrysalis.—J. PATEY, *Gardener, Loseley Park, Guildford.*

CULTURE OF ONCIDIUM PAPILIO.

IN answer to your correspondent, "ORCHIDOPHILUS," the above plant will thrive either on a block or in a pot, provided the proper treatment is given. We have found it succeed well on a block plunged into a pot, so that the block is 3 or 4 inches above the pot's margin, filling the pot with drainage, and a little sphagnum moss or rough peat on the top.

It also succeeds well on a block of wood suspended from the roof, but not too near the glass in winter, as the cold is apt to affect it. If grown in this way a little live sphagnum moss should be placed on the block, and the plant fastened on with some copper wire and small nails.

This *Oncidium* does not require a high temperature: from 55° to 60° in winter is sufficient heat; and in spring and summer it may rise from 65° to 75°, and more by the heat of the sun, from which the plant must be shaded. The plant requires a good supply of water in the growing season, and when at rest just enough to keep the bulbs in a plump state, for if allowed to shrivel it will be a long time before returning to a healthy condition.—B. S. WILLIAMS, *Paradise Nursery, Holloway.*

EXCLUDING GARDENERS IN IRELAND FROM AN EXHIBITION.

It seems to be quite a common proceeding in Ireland not to allow gardeners to enter the place of exhibition on the same footing as you do in England.

I exhibited some Strawberries and Auriculas in Dublin in April last; and on asking the Secretary of the Society for a pass, I was told that there was no pass given, and that I would not be allowed to enter till six o'clock, P.M., unless I had a subscriber's ticket. I, of course, thought it very strange that an exhibitor should not be allowed to see the results; but fortunately I had a friend who gave me a ticket, otherwise I might have staid outside till the company were dispersed.

I write this to let the Belfast and other gardeners see that theirs is not the only society in Ireland that allows such offensive treatment.—JAMES CLEWS, *Gardener, Cloon Mohill, County Leitrim, Ireland.*

[The sooner the horticultural societies in Ireland expunge such a supercilious rule the more creditable will it be for them.—Eds.]

BIRMINGHAM ROSE SHOW.—The prize list of this important Exhibition of cut Roses, garden ornaments, and horticultural implements is now ready, and, as will be seen on reference to the advertisement which appears in another column, may

be had on application to the Secretary, Mr. Alexander Forrest, Queen Chambers, Birmingham, from whom also forms of entry may be had. The last day on which entries of implements and garden ornaments can be made is July 2nd, and of Roses July 9. There is every reason to expect an unusually fine display of the "Queen of Flowers" at this interesting and important Exhibition.

DESTROYING WORMS IN POTS—HEATING FROM A KITCHEN FIRE.

I HAVE several times read in your Journal instructions for destroying worms, but do not remember whether they applied to pot-plants or not. Will you inform me whether any or what application can be made to Vines in pots without injuring the plants? I was repotting a young Vine this morning, and saw more worms amongst the soil than I liked to see. There were a lot of young white ones feeding. I suppose, on some broken bones that were put amongst the soil in the first shift from the small pot the eye was put in. These as well as the larger ones I want dislodged if it can be done without much risk, though so far as my observations go, I do not expect the worms will harm the plants much. They, I think, live on the fat of the soil, and not on the plants.

I beg to ask another question. My glass house or orchard-house is a lean-to, 24 feet by 12, south aspect, 5 feet 6 inches high in front, and 11 feet at back, all glass, ends and side, to 2 feet of the ground. In one corner at the east end, 8 feet by 4, I have erected a kind of stage, having three tiers or forums about 16 or 17 inches wide, and underneath this iron gas-pipes of two-inch bore run from the back of the kitchen fire along the west end of the stage, the front, and back; the pipe and water enter near the bottom of an iron cistern, close to where the pipe comes through the house wall. The same two-inch pipe forms the boiler, made to a bevel with the back of the fireplace, the bottom part connected with the cistern by a return-pipe of 1½-inch bore. I have no means of keeping the fire off the pipe boiler; so that as long as the kitchen fire is in, the water is hot, but never gets to the boiling-point, though it will simmer inside the cistern at the mouth of the flow-pipe, but never bubble. To counteract the heat I have to introduce the outside air, and everything put on to this stage, with regular syringing, grows famously. A young Vine, last winter little thicker than a stocking-needle, is now 6 feet high and three-eighths of an inch thick nearly.

The top form of this stage is about 6 feet from the apex of the roof, between which form and apex of the roof the wall is bare. Now, having given a description of the place, I wish you to tell me if a Muscat of Alexandria Grape will succeed in a wooden box 16 inches square, which, of course, holds more soil than a pot of that diameter, and if it will give an annual supply of fruit when placed on the top form or stage, and trained against the wall, allowing 7 feet for each branch, and a bunch at every foot of length—say about a dozen if needful.

The house designed as an orchard-house, has now nearly assumed the form of a greenhouse, but all wood and glass, has cost me about £20. The labour and work, except the heating apparatus, is all my own; and considering that I never handled a joiner's tool before, I do not think any amateur would despise it. This is information for a man of limited means as mine are. I have only night and morning to work.—W. M.

[Put a couple of spadefuls of quicklime into a barrel of water, stir it well, and when clear water the pots with it. This will destroy the worms, and do good rather than otherwise to the roots. We not agree with you as to the innocence of worms in pots. True, they do not often meddle with roots, but they disturb and unsettle the earth about them, and are apt to neutralise and stop up the best drainage. See what was said on drainage in "Doings of the Last Week," lately, as to keeping out worms. But in using bones and rich manure, the eggs of the worms are often taken into the pot in the compost, and lime water is the best remedy, and it will also act chemically with manure. It is not safe to use it strong for some fine hair-rooted plants, but Vines will not find fault with it.

Your mode of heating the cistern by pipes at the back of

the kitchen fire is ingenious, and, no doubt answers. Covering the cistern and giving plenty of air will neutralise the effect of the heat, and by shutting off that corner you might have a miniature hothouse there. If ever you find the heat too much, the simplest thing would be to shut off the pipes from the fire by a moveable iron back or damper, with an inch or so of air between it and the pipes. We can easily fancy that in hot weather you may have too much heat at that part, and it so a wooden covering would be best for the cistern. We would like the box for the Muscat Vine to be longer than 16 inches square, and so much deep. If 24 or 30 inches long by 16 wide and 16 deep, it would be better. If a heavy crop is taken from a 16-inch pot, it is rarely of much use afterwards, and eight to ten bunches from a Muscat Vine in a 16-inch pot would exhaust it too much for cropping it so every year. Much, however, may be done by removing the surface soil every year, top-dressing with rich compost, and using manure-waterings. You deserve great credit for doing the work so well, and we will be glad to hear how you succeed, and would merely hint, that if confined to 16-inch boxes, we would have several—say two or three instead of one. If the cistern did not occupy all the space, you might also plant a Muscat or two, train them up the back wall and down the roof. The roots would not dislike a little heat from the cistern.]

USE OF TAN AMONG STRAWBERRIES.

In No. 115 a wish is expressed that tan may be tried for keeping strawberries clean. I have a friend that has used it extensively for some two or three years to my knowledge, but I would not write till I had ascertained the result of his experience; yesterday he paid me an unexpected visit, and I at once made inquiries about it, and he says it is the best thing for the purpose he ever made use of. He has a Strawberry garden which produces when in full bearing about sixty quarts per day. The walks are only wide enough for convenience, and he every year covers the whole, walks and all, with tan fresh from the pit and has done this for some years. He puts it on in April, or sooner if doing so accords better with his other garden operations, and long before the fruit begins to ripen the tan is washed by the rains till it is as clean as the dessert plate the Strawberries are to be eaten off. It acts as a stimulant to the plants, saves all trouble of weeding, and the runners strike as freely into it as Ferns into cocoa-nut refuse; beside my friend can go about his garden in any weather without soiling his shoes, and I may add he is an experienced gardener, and not a young one.—WORCESTER.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The annual dinner of this Institution took place on the evening of Friday last at the London Tavern, Bishopsgate Street, when upwards of one hundred members and their friends were present.

The chair was occupied by the Right Hon. the Earl of Ducie, supported by several members of the Council of the Royal Horticultural Society, among whom were Mr. John Clutton, Mr. J. J. Blandy, Rev. Joshua Dix, Mr. James Veitch, and Mr. John Lee. There were also present Mr. Robert Wrench (Treasurer to the Institution), Rev. J. M. Bellew, Mr. Koch, and Mr. Henry Paull, M.P., &c.

The room was profusely decorated with flowers and fine-foliaged plants. The whole end of the room behind the Chairman was a perfect bank, from floor to ceiling, of Geraniums and other showy plants liberally contributed, at no small trouble and expense, by Mr. Charles Turner, of the Royal Nursery, Slough. At the opposite end of the room, occupying a gallery in front of the Chairman, was a brilliant display of female beauty, even more attractive to the guests than the best exertions of Mr. Turner proved to be. Whether it is for the sake of uniformity that the ladies are placed apart opposite to the flowers, so that both may reflect a borrowed beauty on the ruder mass below, we know not; but we strongly suspect if they abandoned the higher regions and mingled among frail mortals, their presence would not be less effective nor their influence less beneficial.

The noble Chairman proposed the healths of Her Majesty and of their Royal Highnesses the Prince and Princess of Wales, which were enthusiastically responded to.

In proposing the health of the Army, Navy, and Volunteers, his Lordship said, "As gardeners we should all hope for the time when swords shall be converted into pruning-hooks; but so long as the evil passions of men continued, that was an event which was not likely to happen as long as the world lasted. It behoved us, therefore, to look to our national defences, and to see that our military, naval, and volunteer services were preserved in a perfect state of efficiency." The toast was responded to in eloquent terms by Major Robinson, of the Hon. Artillery Company.

The Chairman then proposed the toast of the evening, "Prosperity to the Gardeners' Royal Benevolent Institution." His Lordship introduced the toast by remarking that it would be superfluous in him to say anything in favour of an Institution which had now been so long before the public, and which had been productive of so much good to a class of men to whom every member of the community was indebted. A vast number of the pleasures we enjoy are derived from the skill and labour of the gardener; and if evidence were wanting, we have only to look around us, even in the present room, and see the magnificent flowers and fruit with which the walls and tables are decorated. But it is not alone pleasure to the senses that we obtain from the gardener's art. It is well known that some of the most direful epidemics that devastated Europe, and particularly the northern parts, in the middle ages, have totally disappeared by the extended cultivation and use of garden vegetables. Gardeners as a class are intelligent and provident; but there are circumstances over which they have no control, by which they are not unfrequently reduced so as to be dependant on others for support. It was no disgrace for a man to be placed in these circumstances when he had striven hard to maintain a respectable position in society, and he would simply instance two men well known to the greater number of the company present—Mr. Mearns, gardener to the Duke of Portland, and Mr. Sangster, long a member of one of the large seed-houses in London. Both of these men had little expectation at one time that they would ever require to come to this charity for relief, but rather that in their later days they would not only be secure from penury, but were fairly entitled to enjoy some of the luxuries of life. It was for the relief of such cases that this Institution was founded, and he therefore had great pleasure in proposing "Success and Prosperity to the Gardeners' Benevolent Institution."

Rev. J. M. Bellew then proposed the health of the Chairman, remarking that one of the finest characters in the world was an English gentleman with a handsome income, who spent his life on his ancestral estates, diffusing joy and happiness to all around him. Such an English gentleman was the noble Chairman. Who was there connected with agriculture and gardening to whom the name of Earl Ducie was not familiar? But it was not in these pursuits alone that the noble Chairman had distinguished himself. In all the movements tending to benefit the country and society at large, his name and presence were to be found. Even in the volunteer cause he was eminently distinguished, and had taken so decided a part in rifle practice that he might be pronounced to be a *denied* good shot. The toast was received with great applause, and his Lordship briefly returned thanks.

The Chairman then proposed the following toasts:—"Mr. Robert Wrench, the Treasurer of the Institution," "Mr. Cutler, Secretary." His Lordship retired at half-past 9, and the Chair was occupied by Mr. Bellew, who proposed "Success to the Royal Horticultural and Botanic Societies," which was responded to by Mr. Blandy.

Mr. Koch proposed the health of the Committee of Management, and Mr. Child returned thanks. The Chairman proposed the health of the Stewards and of the Ladies, which concluded the entertainment of the evening.

The sum of about £100 was subscribed in the room for the benefit of the Charity.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PERSEVERE in the all-important operation of stirring the surface of the soil at every favourable opportunity. There is no kind of soil which will not be benefited by this operation; but certainly on those having a tendency to run together or bind, it is indispensably necessary. No one who has not followed out the system as the market-gardeners do, perseveringly, can truly estimate the great advantages resulting therefrom. It is very proper to apply stimulants in the shape of manure trenched into and incorporated with

the staple soil, or in a liquid state during the growing season; but the benefit of such applications is greatly increased by continual, and, as far as possible, deep surface-stirring; for it is the external atmospheric influences acting upon, and combining with, the substances composing the food of plants, which reduces them to a state fit to be taken up through the roots, and assimilated by the plants. *Artichokes*, as the heads are cut, the stems to be cut close to the roots; clear the stools from decayed leaves, and loosen the surface of the soil about them with a hoe. *Asparagus*, the beds should now, in the midst of the growing season, and while the soil is moist, receive good soakings of manure water, with a good portion of salt added thereto, taking the precaution of applying in good time stakes and lines to the outside rows at least, to prevent heavy rains and high winds breaking down the plants, which is very injurious to the crowns. *Carrots*, if the aphides make their appearance on this or the Parsnip crop, drudge them well early in the morning with dry wood ashes, charred saw or wood dust, or soot, any of which is good, but the three mixed together have a most beneficial effect, not only in clearing away the nuisance, but also in fertilising the soil, and producing healthy luxuriant crops. If any of the Brassica family are attacked by insects, dredge them in a similar manner, and if attacked by the root maggot, apply soot in a liquid state. *Cauliflowers*, earth-up those that were planted in the beginning of last month; plant more for coming into use in the autumn. *Celery*, the main crops to be got out without delay, the plants to be well supplied with soft water, and to be shaded for a few days if necessary, the early crops to be liberally supplied with liquid manure, and the soil about them to be frequently stirred with a fork, but by no means make any attempt at moulding them up until they have attained the desired growth. *Garlic and Shallots*, as soon as the tops begin to die, take up the roots; after allowing them to remain on the ground a day or two to dry, tie them in bunches, and hang them in the root-cellar. *Onions*, make a small sowing for drawing young. The Tripoli answers well for that purpose; the autumn-sown ones transplanted in the spring are very fine this season, and will now be attaining their full size. When this is perceived lay the tops down for a time previous to pulling. *Sea-kale*, this, like the *Asparagus* crop, is particularly fond of manure water and salt, which may now be applied to assist in forming strong crowns to insure good cuttings of luxuriant, fine-flavoured Kale another year, the crowns to be duly thinned. *Spinach*, sow a few rows to keep up a succession; thin the preceding crop, and keep it watered in dry weather. *Tomatoes*, keep them well thinned-out and constantly nailed. *Turnips*, keep up good successional sowings, of which a good breadth may now be put in; charred refuse or dry wood ashes sprinkled over them when they are wet is a good preventive against the fly.

FLOWER GARDEN.

If the dry and hot weather continue, much watering will be necessary here. Even the ordinary herbaceous plants should have a thorough soaking once or twice a-week. Indeed, it is more necessary with these than with mass flowers, which have now, of course, become well established. Cut back the perpetual-blooming *Roses* as they go out of bloom, and well water with the richest manure water to encourage a second growth and bloom. See that *Hollyhocks*, *Dahlias*, and the taller-growing herbaceous plants are properly secured to stakes, &c., as they grow. The budding of *Roses* to be proceeded with in dull weather. Give plants infested with green fly a liberal washing with the engine, or syringe them with tobacco water. Now is the best season for observing the effect of the arrangement of the colours, &c.; and if any alteration is deemed necessary, it should be carefully noted, which will greatly facilitate its execution at the proper season. As yet, we cannot say that the flower garden at the Royal Horticultural Gardens is as perfect in all its parts as could be wished. There is an undue prominence of some particular colour—viz., scarlet and blue, while others of equal worth are “few and far between.” But it matters not, though we have red, blue, and yellow colours in abundance; if there is an absence of compensatory hues, it would be like having the high notes in music without the low—neither harmony nor variety would be apparent.

FRUIT GARDEN.

The principal operations here will consist in keeping the young wood of wall fruit trees constantly nailed-in, the laterals from the young wood of Peaches and Nectarines to be spurred down to the first joint. Some portion of the young wood of Gooseberries and Currants to be spurred-in at this season, as doing so both increases their productiveness and the fineness of the fruit.

STOVE.

Encourage the progress of the young stock for winter blossoming; and maintain a comparatively moist temperature. An increased circulation of air to be allowed amongst the Orchids during the bright weather that generally succeeds a period of gloom, as the humidity constantly stagnant will otherwise have an injurious effect.

PITS AND FRAMES.

These structures should now be producing for the conservatory or mixed greenhouse, a sufficient number of Cockscombs, Balsams, Globe Amaranths, *Thunbergias*, *Gloxinias*, *Achimenes*, &c. The growth of specimen *Fuchsias* should be duly encouraged, also late-blooming *Pelargoniums*. The Japan Lilies, Chimney Campanulas, and Guernsey Lilies, should be ordered in due time, they are remarkably pretty and useful autumn-flowering plants. See that *Cinerarias* and *Calceolarias* are standing in a cold, shady situation. A quantity of stocky plants of the Scarlet and Variegated *Geraniums*, *Veronica Andersoni*, *Heliotropes*, late-struck *Fuchsias*, &c., should be duly encouraged for late autumn-flowering. Encourage the growth of *Primula sinensis*, they thrive well in light, open, fibrous, sandy loam. The perpetual-flowering *Roses* should not be forgotten, they are good and useful plants in the gloomy months of autumn.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Sowed last Dwarf Kidney Beans in the open air, will sow more in a fortnight, where we can protect from autumn frost. Sowed Dickson's Favourite, Bishop's Longpod, and Early Washington Peas for the last crop unprotected. Staked-up advancing crops as we could get at them and could find sticks, of which we are scarce. In sowing at this season, we make the drill much wider and deeper than usual, sow the Peas wider, but not too thick; soak the drills after sowing, cover with an inch of soil, water more slightly again, and then place half an inch of dry soil on the surface, and strew with a little soot and lime. We also put lime in the water first used to start or kill slugs and worms. Drenched the rows of Peas bearing heavily, and those in full bloom, to help them to set strongly. To keep in the moisture, in some cases, where *Spinach* between the rows was getting old, cut it down, and placed it on at the bottom of the Peas; in other cases, brought short grass and litter, and where that could not be done, hoed the ground, so as to throw dry soil over the watered place to keep the water in by lessening evaporation. Sowed succession of Turnips, Radishes, Lettuces, and the first of Endive, watering and shading as soon as sown. Fraser's Broad-leaved Endive is a most desirable kind for winter work. Sowed also a little Parsley and Chervil, &c., for succession, and as we are scarce put in cuttings of Tarragon and other herbs. Topped late Broad Beans. A little Mazagan and Longpod may still be sown for late crops; but with us sowing after the middle of June seldom does much good. Regulated Cucumbers, turned out more Gherkins, and earthed the last piece of Mushroom-bed in the shed. Those in the house are almost done, and the first piece in the shed, from the rubbishy materials we could command, is coming in. In answer to several queries, we would say, that six weeks from the spawning is a good general time to wait. If forced into growth much earlier, they seldom bear so long. To all who wish to have the best material, however, we still say nothing exceeds in goodness droppings of horses fed on hard food, with about a third of the shortest litter, and the material not allowed to heat too violently before using it.

BIRDS.

A lady and gentleman who called here the other day, were in raptures of delight—and what with, think you? The

swarms of blackbirds, the clouds of thrushes, the numbers of dishwashers or water-wagtails, and starlings (the last two we have taken under our peculiar protection), the swarms of linnets hopping from bush to tree, and ever and anon emitting their sweet plaintive notes, and even the armies of the soot-balls of London—the thieving sparrows. What cared they if the finest Strawberries were nibbled, and the best Peas purloined? “Why we would have a garden for the very purpose, and let the sweet fellows take all they liked, if we could only get such hopping beauties, such choirs of harmony.” It reminded us of a conversation between a lady and her gardener. Says Blue Apron, “I am sadly pestered with vermin, Madam; will you allow me to take means to lessen the evil by destroying the vermin?” “Certainly, why should you be thus annoyed? but what is or are the vermin?” “The birds, Madam, the birds; I must trap and shoot them.” “O! the birds, the beautiful birds! call them vermin! The sweet, lovely songsters! No, indeed. You surely would not have the heart to kill them, and you, too, a man of such kind feelings! Why, my beautiful garden would be a lonely thing without my feathered friends.” And Blue Apron was obliged to be content with grumbling. No doubt he netted and trapped on the sly; but a report of a gun was never heard. Nets must be our great safeguard in such circumstances, then there will be quite enough that will go to the birds’ share, to repay them for what good these hard-billed gentry do us at other times, and we confess that to our own ears there is something sadly out of place in the noise of a gun, and the smell of gunpowder in a garden. It is amazing though, how the hard selfishness of our nature will often ride roughshod over all our best feelings and kindest sympathies. The last time we saw one of our friend bird-admirers, who looked upon us as worse than a Goth, for peppering some sparrows among a favourite quarter of Peas, he was making the whole neighbourhood ring with the rapid discharges of a huge horseman’s pistol. “What, what, are you doing now? you shooting the pretty birds!” And he replied with crimsoned cheeks, “Bother them, they have cleared off my Strawberries, and now they will not leave a pod of this new delicious Pea.” Aye, just so it is; let the shoe pinch in the tender selfish part, and then, notwithstanding our admiration of our feathered friends, there are times when we would wish they gave us less of their attentions, or that means should be used by which we might reckon on having the first gatherings, so as to leave them only beautiful gleanings. Let birds alone, “first served” will ever be their motto.

FRUIT GARDEN.

Tied-up Raspberries that had drooped and broken ties with the weight of fruit. Some grumbled at the frost injuring the Gooseberries just when out of bloom, and many, no doubt, were cut off; but if with us 50 per cent. more had gone, it had been a good thing for the bushes, as they are far too heavily loaded, notwithstanding the quantity taken for bottling. Even now it would be a charity to thin them if we could find the time. One advantage is, there will be little necessity for summer pinching of the young wood, though both Gooseberries and Currants, at all strong, are much more fruitful and easily regulated in consequence. Some of the bushes are rather thin of leaves, which we attribute more to a blunderstorm than to caterpillars, as after early spring we have seen little of the latter. Netted almost every piece of ripening Strawberries, and find that the individual fruit, thanks to the rains coming in time, are coming better in size than we expected at first. Some of the later Keens’ and the earliest Queens have been very good; still the bulk, owing to the dry weather, are rather smaller than usual. At one time it was all the fashion to have Strawberry-bunks, the beds divided by stones, flints, bricks, &c., and the Strawberries hanging temptingly over them. The first necessity for their full success we should consider to be abundance of water near to them. One error, however, it is as well to dissipate, and that is the idea that beds so raised require such an amount of water in addition to those planted on the level quarter. Young plants generally need more at first; but when plants are established and the surface is either kept stirred or mulched, the plants on such banks need no more watering than those on the level. In fact, they are just as independent as the depth of good

earth beneath them is all the more, for the roots will go deeper and the moisture will rise by capillary attraction so long as there is moisture to get. We have known such banks spoiled by merely keeping the surface moist, which kept the roots starved from two causes—the water at the surface did not get down to them, and the line of evaporation being broken there was no rising of moisture from beneath to help them.

Netted all Cherries from which we expected to gather, otherwise we should expect to reap nothing but the stones and the stalks. Kept shortening the points and thinning the shoots of Pears, Apples, Plums, &c. Find our double smoking has pretty well done for the brown beetle among the trees in orchard-house, Peach-house, &c., but it has been a worry. Have heard wondrous tales about a new insect powder, and a sort of piston pepper-box for ejecting it on insects wherever settled or situated. The thing is, those missed are just the mischief and need the looking after. We dislike smoking for many reasons; but still for many purposes it is still the most effectual plan. Painted the backs of frames and pits where Melons are growing, to keep the red spider, &c., at a distance. Watered Peach trees, Fig trees, and Vine-border outside after strewing over it a little soot and superphosphate of lime. Used water about 100°, as it would get cooled in touching the earth, and proceeded with thinning Grapes as fast as we could, as they now require being attended to. Young potted Pines should be slightly shaded and syringed in very bright days, and if shut up early in the afternoon should have a little air all night if the heat inside will permit. From 60° at night, to 85° and 90° during the day, with air and atmospheric moisture in proportion, will suit them better than a high-steaming temperature at night, which renders them too languid to stand a great amount of sun heat without flinching. Bottom heat now should be from 85° to 90°. Removed Cherry trees finished bearing and with buds well formed to an earth-pit, partly plunged the pots, and gave in addition to necessary waterings, good syringings all over with clear soot water, and at times a little sulphur water to keep off red spider or other insects. Those who wish fine-flavoured Oranges of their own growth, should keep their plants under glass and give them plenty of sun temperature. Guavas, where grown should also have plenty of sun and air as the fruit ripens, or it will be insipid. Other matters much in routine.

ORNAMENTAL DEPARTMENT.

Mowing Machines.—Out of doors the chief work has been mowing and machining the lawn and grass between flower-beds. In grass of usual strength the machine ought to be used every four days or so in common weather. There is little economy in using it so as to be forced to go over the ground twice. Some gentlemen have complained to us, that though they can manage with Budding’s, Shanks’, Wilkinson’s, Green’s, &c., when the grass is short and dry, and the ground firm and hard, they can do no good with their machines when the ground is at all mossy, as the knives get clogged up at once and refuse to cut except in seams, that not only tear the muscles of the man’s arms, but leave the work in ridges and furrows and as ugly as a bad-cropped head of hair. To remedy the latter evil the roller or rollers in front should be sunk considerably, which just elevates the knives all that the more, and enables them to cut the grass without plunging down into the moss. In fact, all such matters must be regulated by the roller in front. In going among small beds and going round circular beds, it is of importance that the roller in front, as in Green’s 16-inch machines, should be divided into four equal parts, as then you can go round a circular or a curved line as easily as a straight one. With the roller in one piece you cannot do so, but must take several shorter strokes to get round the circle or curved line. As to cutting grass when wet, though it can be done, we rarely attempt it, but find that the drier and shorter the grass the better the work will be done. For want of regulating by the roller many a machine is left to enjoy itself alone in the tool repository and the old scythe depended on. We were lately consulted as to why a machine would not work. Its roller has been removed as an improvement, and to cut with such a machine at all must have required a very great amount of physical exertion merely to

keep the machine properly balanced. There are nuts in all machines by which the front roller can be elevated for firm ground and short grass, and depressed for longer grass or loose mossy ground, and the knowledge of this simple fact would cause many a machine to be employed that now is useless and unused. We are glad to say that we have had no difficulty with grass-cutters, the men preferring them much to the scythe. We have no doubt that a little patience and gentle encouragement must be given to secure their being used in some places where everything now is objected to. A little of Sam Slick's soft sawder will, judiciously employed, soon be found to conquer all the objections of prejudice.

In the flower garden we presume most of Tulips and spring buds have now been taken up, unless it is resolved to leave them out all the season. Gladioli will stand waterings with manure-water, or may get a rich top-dressing of old rotten dung or leaf mould. Dahlias have been looked over as to tying and watering; ditto as to Phloxes and herbaceous plants in general. Set out a number of *Hollyhocks* in pots that had been struck from the thinnings of good kinds some six weeks ago, and which were inserted under hand-lights over a very slight hotbed. There are now some hundreds of fine plants, which will bloom this autumn. We may take off a lot more when thinning and tying; but these will not do so well, as the young shoots slipped off early when too thick. We have, it is true, struck them from buds even of the thinnings; but all such buds and all such shoots rooted now will require to wait next year for blooming, whilst slips taken off in spring will come nearly as soon into bloom as cuttings struck last autumn. Now is also a good time for sowing *Hollyhocks* to bloom next season, pricking them out on a border when up, and planting out in autumn and spring where wanted to bloom. Now is also a good time for striking under a hand-light, or a shady border, *Pentstemons*, *Phloxes*, perennial *Silenes*, *Heartsease*, and *Pinks*. In order not to disfigure the old plants of the latter, it is best not to cut over the cutting, but to pull it at once out of its socket, and thus the cutting is fit for insertion at once. This is done by holding the bottom of the shoot by the left hand, and pulling the top with the right hand, just at the second joint; most of the pieces, cuttings or pipings, will come out clean from the joint, and with a sounder bottom than you could make with the sharpest knife. This method is not only the best, but saves a deal of time in stripping leaves and base cutting across.

Roses have been mulched, as we could not water them, and some of the stronger shoots have been stopped and nipped. The first massive show of fine sorts against a wall is nearly over. Rose cuttings will do now, but better a month or six weeks hence. Many of the *Antirrhinums* (*Snapdragons*) are very beautiful, and now is a good time to increase the best kinds by cuttings. It may be as well to wait a few days longer if the cuttings are not quite ready. The best cuttings are those that come from the stem below the flower-spikes. When these are about 3 inches long slip them off close to the stem, and insert in sandy soil under a bell-glass in a shady border. If the shoots are thinned many of the side shoots left will bloom later, though the spikes will not be so fine at the first. These *Snapdragons* make beautiful masses in rough or rock gardens; but some people dislike the smell of them very much, whilst other people rather like it. Edged and hoed beds of bedding plants, and have had no end of labour in securing them. They are now filling fast. When the ground is a little warmer we will slightly mulch them in the openings with old Mushroom-dung, &c. Changed plants in conservatory, and gave plenty of water to *Camellias* in conservatory and in hothouses, as if left dry now they are apt to drop the buds that are formed. Syringed *Azaleas* frequently. Potted young *Geraniums*, and many other hardwooded and softwooded plants, &c.—R. F.

ELM LEAVES VARIEGATED.—Who can account for the leaves of Elm trees becoming variegated throughout the whole tree, so as to present an appearance of almost perfect whiteness? The trees in question have assumed this aspect within the last few years, and stand amongst others which remain in their natural state.—W. H. BEADON, *Devonshire*.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

CALCEOLARIAS (*H. J. H.*).—The blooms were much withered and much bruised. They seem to have been handsome but small. Saving seed from the best would probably give you some good varieties.

SENDAL (*An Old Subscriber*).—Such a manufacture is quite out of our province. Consult some Encyclopedia.

TWELVE CAMELIAS (*J. R. H.*).—So far as we know them, those in your list are all good. For twelve we would select from it—*Augusta*, *Alexia*, *Chandlerii*, *Caryophyllodes*, *Hendersonii*, *Jubilee*, *Mathotiana*, *Pensylvanica*, *Perfection*, *Rubini*, *Verschaffeltiana*, and *Viscontea nova*.

TIME FOR CUTTING-DOWN GERANIUMS (*A Subscriber*).—It is best to have successions of *Geraniums*. We have cut them down at times varying between July and the end of September, and found they succeeded equally well; but, of course, those cut late were later next year than those cut early, and had small foliage until the spring.

MILDEW ON CUCUMBERS (*N.*).—It is just possible that the slate in both cases gets too hot, but the chief cause of the mildew may be owing to deficient ventilation. We would use sulphur freely over the slate, and give at night and day. We should not like the roots getting through the slate. We would make it secure-jointed, place 6 inches of rubble over it, and have holes at the sides to make sure that the water poured through the pipes never stood higher than 1½ inch over the slate. In the other bed we would do the same; but as the sides seem comparatively open, to secure top heat we presume, you could not expect the same bottom heat there. With such an open chamber, the case of "Pinks versus Pipes" has not a fair chance. To insure a fair comparison both chambers should be equally shortened, and moisture presented equally to both slate coverings. Mere dry heat will not rise so quickly and regularly by itself as when it is accompanied with hot vapour.

HEATING A CONSERVATORY (*H. Gibbons*).—Your sketch gives no information about the levels. If the boiler in the aviary is a foot or 18 inches below the base of the garden and the drawing-room doors there will be no difficulty whatever. You could not well make a junction from the pipes in the aviary, unless the pipes were as high in the house to be heated. You might do this by bringing the pipes as far as the doorway, and causing them to return from thence without passing the doorway. In fact, you might have all the heat you want from a stack or pillar of pipes without the pipes going round the house at all. A small brick Arnett's stove would no doubt do the work well, but then you would require a chimney. Most likely the hot water would be the best and least troublesome. If you gave us a section of aviary, boiler, and house to be heated, showing the level of boiler, doorways, &c., we would be more sure.

VARIOUS (*Ezra Miles*).—The best time for moving Briar Roses for budding is any time from the fading of the leaves until they begin to grow in the spring, the sooner in the winter the better. Take the Briars up carefully, prune the roots to 6 or 8 inches from the stem, prune off all shoots from the stem, and leave it at the desired height, plant in good rich soil so as to encourage fibres near home, and as soon as growth appears, prune all off along the stem except one or more shoots at top, and had these close to the stem as soon as the dark runs and you can get buds well developed. See Mushroom culture in a late Number. Six weeks is a general time after spawning and earthing-up; but we have gathered in less than three weeks, and had them as long as ten or twelve weeks. In ordinary circumstances, six weeks is what we calculate on, and it is very rarely we have been disappointed for thirty years. We think that such things as *Maurandias* and *Lophospermums* in small pots will suit you, and so would such *Nasturtiums* as *Tropaeolum tricolor* and *pentaphyllum*.

IPOMEA HEDERAEFOLIA CULTURE (*Felirstone*).—We suspect your plant is the *Quamosit hederifolia* of Paxton, a rather tender annual from Brazil, which will blow in a warm sheltered place in the open border, it turned out about the beginning of June. If these conditions cannot be given, it will flower well on a rough branch if kept under glass. There is even still much confusion with some of these plants. For instance: A small, scarlet, very beautiful convolvulaceous plant is sometimes called *Ipomoea coccinea*, *Ipomoea quamosit*, and *Quamosit coccinea*. This, too, like *hederifolia*, raised on a hotbed, hardened and turned out in June, will do well in a warm place, but north of London in most seasons it will do best under glass.

CALCEOLARIA VIOLACEA (*G. K.*).—We are not quite sure of the variety you mean. If it has pinnate leaves and small lilac-violet flowers, it would flower best in spring and early summer in the greenhouse, and would do best if kept in pots. If put out of doors it will do best plunged to bloom free. If it is the sort we imagine it will not blow freely out of doors, unless in a warm sheltered place, and even then it would be better if kept in a pot plunged.

WIGHTS USED FOR FRUIT (*Subscriber*).—The pound of sixteen ounces is the weight employed at our London exhibitions and at Covent Garden in weighing fruit.

WORK ON GARDENING (*An Amateur*).—You can have "The Garden Manual" free by post from our office for twenty postage stamps. It will give the information you mention.

FLORISTS' FLOWERS (*Chas. Oldham, Wrexham*).—We do not think that the flowers sent are superior to many in cultivation. It would be well if all raisers of seedlings had a few of the best of those cultivated to compare with their own productions.

SEEDLING PANSY (*T. C. H., Little Wymondley, Steevinge*).—The Pansy is certainly very black, but so are several of those now in growth; and in shape it was little better than the wild one. It might answer for bedding purposes if free-flowering enough.

SEEDLING PELARGONIUM (*Christine*).—The seedling Pelargonium is not, we should consider—unless it has some very peculiar properties in freedom of bloom, &c.—worth cultivating.

SEEDLING CALCEOLARIAS (*H. Major, Knauthorpe*).—The seedling Calceolarias are very fine; the size of the flowers and the brilliancy of the markings being alike conspicuous. We wonder much why the flower is not more cultivated. It deserves to be generally grown.

STRAWBERRIES.—We have received from R. Webb, Esq., Calcut, near Reading, a basket of immensely large Strawberries which Mr. Webb calls "Refresher." It is somewhat like Sir Harry or some member of the race. The flavour was excellent, and one in the basket measures 9 inches in circumference!

BROAD BEANS FALLING (—).—The fleshy knobs or excrescences on the roots of the Beans are quite natural, and have nothing to do with your crop falling. You will find similar excrescences on the roots of greater part of the tribe of the pod-bearers which are cultivated for food—viz., Peas, Beans, Lentils, &c. We could not detect any fungus nor anything the matter with the roots. We can, therefore, only guess at the cause of your crop falling. Perhaps your land is light, and the crop raised in the dry weather for want of moisture. The plants may have been infested with the bean aphid, or the flowers poor with abortive pollen.

GRAPES DISEASED (*T. F. C.*).—The enclosed berries were badly spotted. The pavilion on the eastern side of the vineyard would materially aid in bringing about the diseased condition of the berries. The Canon Hall is more liable to the spot than most others. It requires a dry hot atmosphere to have it in perfection. The shading from the pavilion would prevent the sap taken up by the roots from becoming thoroughly elaborated in the leaves, and in that crude state it entered the berries no doubt. We know of no remedy but keeping the berries dry during the ripening process, and keeping the roots not too highly fed, near the surface, with the full sun rays over them continually without shade.

NAME OF FRUIT (*Thomas Record*).—Your Grape is Chasselas de Falloux, as described in Hogg's "Fruit Manual."

NAMES OF PLANTS (*Barrie*).—*Echlonia macrantha*. (*P. H. G.*)—4, *Campanula trachelium*. The other three too shrivelled. Flowers for recognition must be sent in a fresh state, or we cannot afford the time required to name them. *Arceuthobium*.—1, *Periclyptera mucronata*; 2, *Fabiana imbricata*; 3, *Hematanthemum tomentosum*; 4, probably *Paulownia mexicana*. The others were too shrivelled for identification. (*H. E. Herts*).—1, *Cynoglossum sylvaticum*; 2, *Hypericum androsaemum*; 3, *Lychnis alba nemorum*. (*Cochrane*).—It is, I fancy, *Trigonopogon perfoliatus*. There must be some mistake. (*P. S.*).—1, *Thalictrum flavum*; 2, *Medicago lupulina*; 3, insufficient; 4, *Baliota mara*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

JULY 20th to 24th. WORCESTERSHIRE. See, Mr. J. Holland, Chestnut Walk, Worcester. Entries close June 20th.
JULY 30th and 31st. EASTERN COUNTIES (Stowmarket). See, Messrs. W. G. Hanson, and A. Sampson, Stowmarket. Entries close July 25th.
AUGUST 25th. POKERINGTON. See, Mr. T. Giant. Entries close Aug. 17.
AUGUST 29th. BALFAX and CALDER VALE. See, Mr. W. Irvine, Balfax.
SEPTEMBER 2nd. COTTINGHAM. See, Mr. J. Brigham.
SEPTEMBER 2nd. WARTFIELD and WEST RIDING. See, Mr. J. Crossland, jun, Wakefield. Entries close August 24th.

CHINESE PHEASANTS.

IN "La Maison de Campagne," a French periodical, is a notice of Pheasants, and among them a description of the Chinese, which we have thought worthy of being translated. We are more especially moved to do so because we have frequently said, we believe, that Pheasants may be profitably kept as a hobby.

"This bird has not been long known in France, and yet it has been so extensively crossed with the common that it is difficult to procure pure birds. The cock should have a sharp head; long thin neck, divided in the middle by a large white ring; neck violet shaded; the lower part of the back and the wings clear green (grey, light blue); the sides yellow; but every feather forming the side-coverts should be marked at its extremity with a regular black point. The tail is short, pointed, brown, and transversely striped. The female is smaller and thinner in shape than the male, her plumage is of an ashen grey with violet shades.

"The Indian is at once distinguished from the common Pheasant by his smaller head, and the manner in which he carries it thrown backward, and by the almost perpendicular carriage of the tail when the bird is walking. The half-bred Indian is a large bird, and recognised by the green on its back which has a red tint, by its wings which are grey instead of green, and, above all, by its sides which are

irregularly spotted on a yellow ground with red shades, as in the common Pheasant. It is also less wild than the pure bird, in which wiliness seems a characteristic of the breed. The Indian begins laying from the 10th to the 30th of April, and finishes in June; lays from thirty to forty eggs, colour dark olive, nearly round, and much smaller than those of the common birds. The hens lay many more the second than the first year. The breeding-birds should be tresh-mated every five years. A pen 9 feet square will serve for a cock and five hens.

"The Indian poult is may be distinguished from the first by two very dark black stripes they have on each side of the forehead. The black stripes they have on the body are also much plainer than in the common poult.

"In taking account of the qualities and defects of the Indian, it is hard to decide whether it is superior to the common breed. It is certainly handsomer, it lays more freely, the young hatch better and come out stronger, but it is subject to the same weakness. It is besides extremely wild, and often kills itself against the top of its pen or cage, unless this covering be common network, or the birds have one wing cut. When turned into the woods there is no hope of ever catching it again, its suspicious character drives it from the trap, although suffering, it may be, from hunger. It flies much better than the common bird, but it takes advantage of this to change from one place to another, if disturbed often. We believe it can only be kept on large domains."

SHEFFIELD POULTRY AND PIGEON EXHIBITION.

THE Poultry Exhibitions hitherto held at Sheffield have always been carried out under the pressure of many difficulties; hence arose the numerous changes of management, and also the impression became general that such meetings would be no longer carried out, on account of the impossibility of finding a gentleman willing to take the responsibility incurred. At length, however, success seems to have followed closely on the energetic means this year adopted to secure this Show's annual perpetuity. By far the best of all the Sheffield shows of poultry has been the result, and the Exhibition of Pigeons has certainly never been equalled out of the metropolis. We are glad to add that the weather being also favourable, a very highly respectable and numerous company were drawn together on this occasion. As might be anticipated, the pens of Messrs. Turner, of Sheffield, than which none are more effective, were those used by the present Society. It is scarcely necessary to say, the Cromore Gardens at Sheffield afford every possible convenience for such a meeting, whilst the rural and extensive views in all directions are not trifling adjuncts in calling together a numerous assemblage of visitors, from among those more particularly whose daily avocations confine them within the precincts of densely-populated neighbourhoods. It is only just to add the birds were well fed and attended. We will briefly remark on the principal classes.

The old birds of *Dorkings* were not shown in large numbers, nor was their condition that of birds just now fatted for an exhibition, the early moult of the present season precluding it altogether. Still, there were among them many pens that in a few weeks might be shown very advantageously. The *Dorking Chickens*, on the contrary, were really first-rate.

Old *Spanish* necessarily showed to the worst possible advantage, for the reason just assigned in the adult *Dorking* class; *Spanish*, perhaps, being the most affected during moult of any poultry. The first prize went to Mr. Garlick's celebrated pen; but the second and third were withheld. In this variety the *Chickens* were not numerous, but exceedingly good. The class for *Spanish Hens* was a perfect one, and one of the most closely-competited in the show.

The *Cinnamon* and *Buff Cochins* also showed to very great advantage, whilst in the *Brown* and *Partridge-coloured* class the contest, though confined to two pens only, was unusually good. Certainly Captain Heaton, though successful, has never before been pressed so closely. The only representative of *White Cochins* was Mr. Dawson, but they fully maintained the credit of that gentleman's yard.

The *Brahmas* were better than at any previous Sheffield Show.

All the *Game* classes were well filled, the birds being excellent, and high condition was almost the universal order of the day. Mr. Charles Challoner showed birds that would indeed be hard to beat in any show, the condition, plumage, and the character of the birds, being alike faultless. Mr. Helliwell's Duckwing cock was also a very worthy competitor in the *Single Game Cock* class, nor were his pen of three in the same variety less praiseworthy.

The *Malays* at Sheffield were such as no previous meeting in this neighbourhood ever possessed; the birds of Mr. Ballance, of Taunton, being the successful ones.

The *Hamburgh* classes, though so good, showed as all such varieties of fowls at this season must do, the disadvantages of moulting time; nevertheless, the competition was a remarkably close one. The rivalry in these classes during the coming winter season of 1863 will most probably be beyond precedent.

Never were *Polands* so scantily shown. Of Black White-crested, although two classes were specially appointed them, not one pen was even entered.

The *Sébright Bantam* classes were equally void; but the *Game* and *White Bantams* were really above par.

Mrs. Seamons, of Aylesbury, took all the prizes for *Aylesbury Ducks*, with such birds as that lady alone can exhibit, and it is as worthy of remark the *Emden Geese* from the same breeder were equally unexceptionable. Mr. Fowler's *Rouen Ducks* were really excellent. Three pens of extraordinarily good *Buenos Ayrean Ducks* were shown, but all in immature feather.

In *Pigeons*, the Sheffield Show this year must rank among the highest; and when we inform our readers that the renowned stock of Mr. Peter Eden were shown in full force, regret must prevail among those Pigeon-fanciers who did not avail themselves of a sight of the Sheffield collection. That gentleman's triumph was necessarily complete, being first in both the *Carrier* classes, first and second in both the *Pouter* classes, with such *White* ones as make all who see them covet; first in *Almond*, and also other *Tumblers*; first and second in *Barbs*, besides other minor premiums. The class for "New, or any distinct variety" of *Pigeons*, was a perfect treat to any lover of those birds; in fact, we never before saw four pens of *Runts* together so good as were here shown, and we must not omit very favourable mention of both the *Archangels* and *Icelanders*.

The *Rabbit* pens were well filled with capital animals, but a keen view prevailing, they seemed as though inclined to whisper "no place like home;" the open exhibition ground being a most extreme change from their customary hutches.

DORKING (Silver-Grey).—Prize, J. K. Fowler, Aylesbury.

DORKING (Coloured, except Silver-Grey).—Prize, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley.

DORKING (Aly colour).—*Chickens*.—First, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley. Second, F. Key, Sheffield. Third, Rev. J. G. A. Baker, Biggleswade, Beds. Commended, Rev. J. F. Newton. *Cock*.—First, H. W. B. Berwick, Helmsley, Yorks. Second, J. White, Warlaby, Northallerton. Third, T. Tatham, Kington, Northampton. Highly Commended, Rev. J. G. A. Baker. *Hens or Pullets*.—First and Third, H. W. B. Berwick, second and Highly Commended, Rev. J. G. A. Baker.

SPANISH.—First, J. Garlick, Liverpool. Second and Third withheld. *Chickens*.—First, J. R. Rodbard, Winton, Bristol. Second, J. K. Fowler, Aylesbury. Highly Commended, T. Greenwood, Dawbury. *Cock*.—First, H. Beldon, Bradford. Second, J. R. Rodbard. Third, J. Smith. Highly Commended, E. Brown, Sheffield. *Hens or Pullets*.—First, J. R. Rodbard. Second, H. Beldon. Third, Master H. Chad, Aston. Highly Commended, S. Robson, Brotherton; Mrs. Brown, Sheffield.

COCHIN-CHINA (Cinnamon and Buff).—Prize, T. Stretch, Ormskirk. *Chickens*.—First and Third, J. H. Barker, Sheffield. Second, F. W. Earle, Edenhurst, Pre-coat.

COCHIN-CHINA (Brown and Partridge).—Prize, Captain Heaton, Manchester. Highly Commended, K. White, Sheffield. *Chickens*.—Prize, J. Stephens, Walsall.

COCHIN-CHINA (White or Black).—Prize, W. Dawson, Hopton Minfield (White). *Chickens*.—Prize, W. Dawson (White).

COCHIN-CHINA.—*Cock*.—First, T. Stretch, Ormskirk. Second, J. Wright, Woodridge. Third, S. White, Tideswell. Fourth, H. W. B. Berwick, Helmsley. Commended, R. White, Sheffield. *Hens or Pullets*.—Prize, H. W. B. Berwick.

BAHMA-LOOBA (Light or Dark).—First, J. Hinton, Hinton, Bath. Second, Mrs. M. Seamons, Aylesbury. *Chickens*.—First, J. K. Fowler, Aylesbury. Second, J. Hinton. Third, Mrs. M. Seamons. *Cock*.—First, J. Hinton. Second, J. K. Fowler. Highly Commended, J. Pares, Chertsey.

GAME (White and Piles).—First, A. Guy, Eaton. Commended, G. Helliwell, Sheffield. *Chickens*.—Prize, A. Guy.

GAME (Black-breasted and other Reds).—First C. Challoner, Steeley. Highly Commended, G. Helliwell, Sheffield. *Chickens*.—First, C. Challoner. Second and Third, H. Snowden, Great Horton. Commended, C. W. Laxton, Nantwich; W. Bentley, Scholes; W. H. Wordsworth, Chesterfield.

GAME (Black and Brassy-winged, except Greys).—First, G. Helliwell, Sheffield. Second, W. W. Ballard, Leamington.

GAME (Duckwings and other Greys and Blues).—First, G. Helliwell, Sheffield. Third, S. Slater, North Carlton. Second withheld.

GAME (Any colour).—*Cock*.—First, C. Challoner, Steeley. Second, G. Helliwell, Sheffield. Third, G. Wostenholme, Sheffield. Fourth, J. Wharrie, jun., Rotherham. Highly Commended, T. Bramhill, Sheffield; G. Wostenholme. Commended, E. Aykroyd, Bradford; J. A. B. Greaves, Ecclesfield. *Hens or Pullets*.—Prize, W. Bentley, Scholes.

MALAY.—First and Second, Master C. A. Ballance, Taunton. Highly Commended, A. Sykes, Mile End, London. *Cock*.—Prize, Master C. A. Ballance.

HAMBURGH (Golden-pencilled).—First, W. Froggatt, Walkley, Sheffield. Second, S. Smith, Northwram, Hallifax. Third, J. Pritchett, Edgbaston. *Chickens*.—First, H. Pickles, jun., Early, Skipton. Highly Commended, S. Smith. *Cock*.—First, H. Beldon, Bradford. Second, W. Bolton, Sheffield. Third, G. Hancock, Sheffield. Commended, T. Crookes, Sheffield.

HAMBURGH (Golden-spangled).—First, G. Brooke, jun., Huddersfield. Second, H. W. B. Berwick, Helmsley. Third, J. Roe, Hadfield. *Chickens*.—First, Mrs. A. Roe, Hadfield. Highly Commended, G. Brook, Huddersfield. *Cock*.—Prize, H. Beldon, Bradford.

HAMBURGH (Silver-pencilled).—First, Miss F. Harrop, Walkley, Sheffield. Second, C. Moore, Poulton-le-Fylde. Third, H. Beldon, Bradford. *Chickens*.—Prize, Mrs. J. Harrop, Walkley, Sheffield. Highly Commended, A. Nicholson, Walkley, Sheffield. *Cock*.—Prize, H. Beldon.

HAMBURGH (Silver-spangled).—First, H. Beldon, Bradford. Second, T. Davies, Newport. Highly Commended, A. Newton, Sildon, Leeds. *Chickens*.—First, W. Bownes, Sheffield. Second, H. Bancroft, Stanington. Third, T. H. Turner, Sheffield. *Cock*.—Prize, H. Beldon.

HAMBURGH (Golden or Silver-pencilled).—*Hens or Pullets*.—Prize, G. Helliwell, Walkley, Sheffield. Highly Commended, J. E. Powers, Biggleswade, Beds.

HAMBURGH (Golden or Silver-spangled).—*Hens or Pullets*.—Prize, Mrs. Birch, Sheffield.

POLANDS (Golden).—Prize, H. Beldon, Bradford.

POLANDS (Silver).—Prize, W. Newsome, Bingley, Yorks.

POLANDS (Golden or Silver).—*Chickens*.—Prize, J. Hinton, Hinton, Bath. *Cock*.—First, F. Hardy, Bradford. Second, H. Beldon, Bradford. Commended, F. Hardy.

GAME BANTAMS (Black and other Reds).—Prize, Hon. W. T. Fitzwilliam, Rotherham. Commended, W. Ilingsworth, Sturton, Retford.

GAME BANTAMS (Other varieties).—Prize, W. Silvester, Sheffield.

GAME BANTAMS.—*Cock*.—First, Miss Brown, Sheffield. Second, G. Helliwell, Walkley, Sheffield. Third, W. Wood, Sheffield. Commended, W. L. Mason, Chesterfield; A. Sykes, Mile End, London.

BANTAMS (Black or White).—First, J. Wade, Leeds. Second, Miss K. Charlton, Lealroad.

BANTAMS (except Game).—Prize, J. Wade, Leeds.

DUCKS (White Aylesbury).—First, Second, and Commended, Mrs. M. Seamons, Aylesbury.

DUCKS (Rouen).—Prize, H. Beldon, Bradford. Commended, J. K. Fowler Aylesbury.

DUCKS (Black East Indian).—First and Second, C. A. Ballance, Taunton. Highly Commended, J. E. Jessop, Hull.

GEESSE.—Prize, Mrs. M. Seamons.

PIGEONS.

CARRIERS.—*Cocks*.—First and Third, P. Eden, Salford. Second, J. Smith, Sheffield. Highly Commended, S. Robson, Brotherton. *Hens*.—First, P. Eden. Second, H. W. Edmonds, Westminster, London. Third, H. Beldon, Bradford. Highly Commended, W. H. Edmonds. Commended, P. Eden.

POUTERS.—*Cock*.—First and Second, P. Eden, Salford. Third, H. Beldon, Bradford. Highly Commended, W. Taylor, Sheffield; H. Brown, Walkley, Sheffield. Commended, M. E. Jobling, Newcastle-on-Tyne. *Hens*.—First and Second, P. Eden. Third, W. Taylor. Commended, G. Ure, Dundee.

TUMBLERS (Almond).—First, P. Eden, Salford. Second, F. E. Else, Bayswater, London. Third, H. Beldon, Bradford. Highly Commended, W. H. Edmonds, Westminster, London.

TUMBLERS (Any other variety).—First, P. Eden, Salford. Second, H. Beldon, Bradford. Commended, F. E. Else, Bayswater, London.

FANTAILS.—First, Miss Brown, Sheffield. Second, P. Key, Beverley.

JACOBS.—First, H. Yardley, Birmingham. Highly Commended, F. Key, Beverley.

TRUMPETERS.—First, S. Robson, Brotherton. Second, H. Yardley, Birmingham.

BAKES.—First and Second, P. Eden, Salford. Third, H. Yardley, Birmingham. Highly Commended, Mrs. Taylor, Sheffield.

TURBITS.—First, J. R. Jessop, Hull. Second, H. Beldon, Bradford. Commended, J. Wade, Leeds.

OWLS.—First, F. E. Else, Bayswater, London. Second, H. Beldon, Bradford. Third, M. E. Jobling, Newcastle-on-Tyne. Commended, H. Beldon.

BEARDS.—Prize, F. E. Else, Bayswater, London.

ANY NEW OR DISTINCT VARIETY.—First, T. D. Green, Saffron Walden. Second, H. Yardley, Birmingham. Third, J. Smith, Sheffield. Highly Commended, T. D. Green; J. Wade, Leeds.

RAZEMITS.—For Length of Ears.—Prize, W. White, Sheffield. For Colour.—First, W. J. Pope, Biggleswade, Beds. Second, W. Chamberlain, Desford, Leicester. Third, R. W. Freestone, Rotherham. Highly Commended, W. Hudson; W. Littlewood, Chesterfield. For Weight.—First, J. Warner, Chesterfield. Second, P. Jones, Sheffield. Highly Commended, W. L. Mason, Chesterfield.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, officiated as the Judge both of the Poultry and Pigeons.

EASTERN COUNTIES POULTRY SHOW.—We are informed that great exertions are making to render this a first-class Exhibition, and we hope that it will be successful. The plan adopted at this Show and elsewhere, of giving prizes pro-

portionate to the number of entries we think very good. Thus, if there are only five entries in a class, the first prize will be only £1, but if there are twenty entries that prize will be £3, the second and third prizes being increased at a similar rate.

CRYSTAL PALACE SUMMER POULTRY SHOW.—A report has been circulated that this Show is to be discontinued. Our readers will be pleased to hear that the Directors of the Crystal Palace have the subject under consideration, and it is most probable that next week we shall be able to announce the days on which the Show will be held.

DRONE-BREEDING QUEENS.

IN reference to the hive mentioned at page 406, in which drones appeared on the 24th of April, I may add that it had not been fed either last autumn or this spring; therefore, might not be supposed to be in a more advanced state than other vigorous hives at the same season. As your correspondent "L. & W." had strong stocks in his apiary, it cannot but be supposed that there were drones in some of them earlier than he had observed, especially in such a mild climate as Somersetshire; for even so far north as Northumberland drones were down early in May. The hive A, with a pure Ligurian queen, he reports as very populous and active, and no doubt its drones were early; so that even if the queen of B should prove all that could be desired in point of the purity of her progeny, "B. & W." can scarcely have a plea in favour of drone-breeders in spring; rather, I imagine, the verdict of English bee-keepers will accord with that of their German brethren, recorded at page 285 of last volume, however painful its execution may be to the tender-hearted apiarist. As "A DEVONSHIRE BEE-KEEPER" proposed, at page 270 of last volume, to try the same experiment with the family of a drone-breeding queen, and your readers have not been favoured with an account of its success in impregnating young queens before the natural time for the appearance of the drones, I infer that it has also failed. In short, it appears as necessary that there should be a high temperature, as that there should be drones in existence.

Can "B. & W." say what had been the maximum temperature about the end of May? as it would be interesting to ascertain the lowest temperature in the shade at which fecundation has been known to take place.

The importance of having a prolific queen at the head of a family in autumn cannot be overrated; but perhaps this did not occur to "A. W. B." who writes under the head of "Swarming Difficulties," at page 425 of last volume, as it appears two families were united to his weak stock, while no mention is made of the removal of the queen. It is a good rule never to retain the queen of a hive which is weak in numbers in autumn; but in forming unions to select that queen which has the largest population. I do not go so far as to say that weakness is invariably to be laid to the charge of the queen, as it is possible other contingencies may have been the cause; still, if there are two or three queens to select from, the extra trouble of driving and removing that which may be under suspicion would be more than repaid by the future prosperity of the hive.—INVESTIGATOR.

[Premising that I have already fully indorsed the conclusion of German apiarists as to the general uselessness of drone-breeding queens, I have pleasure in stating the result of my own experiment. My virgin queen is still living and still lays the eggs of drones only, but her fecundity is not nearly so great as I anticipated, whilst providing her with workers to perform the ordinary duties of the hive is no small tax on the resources of my apiary. On one occasion only can I imagine that she, or rather one of her drones, has done good service, and that is in the impregnation of a young queen hatched on the 14th of May, which commenced egg-laying on the 30th of the same month. In this case I had no drones but these of her breeding, with the exception of a very few in one of my other stocks, and these latter were destroyed during the wet weather we had in June. Whilst agreeing with "INVESTIGATOR," that a tolerably high tem-

perature is necessary in order to render the services of drones available, and that, therefore, it would probably be of little use to attempt queen-rearing much before the natural time—in reliance upon the progeny of a drone-breeder, I may yet point out that drones produced in this abnormal manner are by no means so liable as others to be destroyed on the occurrence of bad weather, and that this in bad seasons is no small advantage where the presence of drones is really of importance.—A DEVONSHIRE BEE-KEEPER.]

QUEENS CHANGING COLOUR.

THE heading of one of your last communications from apiarist friends—viz., "The Variation in Colour of the Honey Bee," tempts me to announce "a sport" which has taken place in one of my hives.

I have been a bee-keeper since 1848—have kept them in three counties—have been a close observer of their habits; and although I have generally gained a wrinkle every year of my bee-keeping existence, I never observed any variety in the colour or appearance of the queens till this year in the hive above alluded to, after its swarming for the third time. There is in it a queen striped round her body as if with yellow bands. I have had little or no experience with Ligurians. I am not aware that there is a Ligurian stock within miles of my present abode. It is possible, but not probable, there may be three or four miles off. I took, however, my hive last autumn to some heather near to Aldershot; there my old queen might have got a cross. Will one of our entertainers and instructors in bee-keeping be kind enough to vouchsafe an attempt at a solution of this difficulty respecting the colour of a queen? I can satisfy a bee-friend that I have heard piping in three instances where I am certain no swarm could have escaped without my knowledge. In those instances I imagine the old queen, instead of leading-off the dance, touched a bucket with her toe.—A HAMPSHIRE BEE-KEEPER.

[We have no doubt that the old queen met a Ligurian drone somewhere, and that the yellow-banded queen is the progeny resulting.]

OUR LETTER BOX.

DORKING FOWLS (L. F. R.).—White feathers are quite unimportant, but they are not desirable. A bent comb is a great disadvantage to a cock, and would tell against him in competition. Dark spots on the breasts and backs of hens are not in any way a defect. We have seen them in many of the best birds we ever had to do with. There is no better or harder breed than the hens that have brown plumage, with dark spots and high crests.

COCHIN-CHINA FOWLS (Subscriber).—The best plates of poultry that have been published are those in the "Poultry-Book," edited by the Rev. W. W. Wingfield and G. W. Johnson, Esq. In some breeds, as in Spanish, the comb, even at six weeks old, is sufficiently developed to mark the sex; but in others, as in Cochins, it is much longer before it is developed. In Cochins you will find the head of the cocks much coarser than the pullets, and the tail-feathers curled and light like those of the Ostrich. It is impossible to fix an exact time for pullets to lay, but well-fed May chickens ought certainly to lay in November. We have known them to do so in October. Your last question is the most difficult. You should be satisfied if you hatch half. We do not consider ordinary travelling very injurious to eggs for sitting.

THE WOODBURY STRAW HIVE.—In the reply to "A. B. C." which appeared last week you state that the Woodbury straw hive "is usually fitted with a wooden cover." This is quite correct if it refers to the outer case which protects the hive, but may mislead many if it is taken to refer to what in wooden hives is termed the "crown-board." This latter is in point of fact made of straw worked in a square wooden frame.—A DEVONSHIRE BEE-KEEPER.

CELESTINE FOR THE TOOTH-ACHE (Colandrea).—We are not aware of this, *Cheledonium majus*, being recently used for removing teeth, but Parkinson, two centuries ago published as follows:—"The juice or the decoction of the herb gargled between the teeth that ache, taketh away the pain, and the powder of the dried root laid upon an aching, hollow, or loose tooth will, as they say, cause it quickly to fall out."

LONDON MARKETS.—JULY 6.

POULTRY.

As the supply increases the price diminishes, and the season of the year pointing to a declining trade is not without its influence.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 74.9°, and its night temperature 51.2°. The greatest heat was 92½°, on the 14th, 1847; and the lowest cold, 39°, on the 18th, 1851. The greatest fall of rain was 1.60 inch.

THE SPADE.

READERS of THE JOURNAL OF HORTICULTURE must be much obliged to the correspondent who so ably described the market-gardening of West Cornwall; and amongst other notices mentions the ground as being dug over and the Potatoes taken up with the Cornish spade or shovel.

I believe there would be great difficulty in inducing any other class of workmen to use this implement. One we have at Linton lies about, and is regarded more as an object of curiosity than an article to work with. In shape the plate is exactly like the spade on playing-cards, and on that account may either claim antiquity or distinction. The handle is either a plain, round, straight one, like that of a hayfork, or with a slight curve, but no top cross-handle. There is also a little bend at the neck. In this respect these spades differ from the

navvy spade of the same form. In digging it is easy to perceive they are better adapted for entering the ground than for lifting any great quantity of mould from it; and it is easy to understand that much less power is required to force them into the ground than the ordinary square-mouthed spade, but in the latter the hand assists more in that duty. The unevenly-broken bottom of the cultivated surface may, however, be better suited to vegetation when the work is done with the Cornish spade than when it is performed with the ordinary one, as we have every reason for believing that digging is better than ploughing from the same cause; still we cannot admit the implement to have any claims to general adoption, and doubt not but time will see its final abandonment.

Taking a wide stride—or shall we say voyage?—up the channel to the other extremity of our triangular-shaped country, we shall land in Kent, and there we find that no county certainly presents a greater extent of surface under hand-cultivation; and it is not too much to say that, taking a circuit of several miles from where I write, the extent of ground under the plough is not double of that under the spade. This is a large proportion, but in some parishes the quantity under hand-culture is double that under plough; and it might be thought that where so large an area is operated upon, those engaged in the work would for their own interest have long ago found out the best implement for the purpose; yet I expect the tiller of the soil in other counties would shrink from the use of the Kentish spud, as it is locally named, as

much as from the Cornish spade or shovel. Still we have no right to condemn the practice of others until we have duly inquired into all its bearings, and very often we shall find our hasty condemnation was without a cause.

The Kentish spud is certainly not a tool commending itself to the amateur. It is in many instances of great weight, the handle-socket reaching almost up to the top; and the prongs, three in number, are flat at their points, and gradually become square as they unite with the cross-piece. The neck is much bent, so as to point the prongs very much forward when the implement stands upright. The advantage of this is to enable the digger to get over a larger space of ground by digging shallow; and as prongs are less hurtful amongst roots than a square-edged spade, the implement is of course adapted to the Hop-gardens and fruit-orchards, which constitute so large a part of the ground cultivated in this way. Most ordinary digging of plain ground is also done with the same implement; and whether such be clayey or stony the strong tines of the spud find their way downwards better than the spade would do. In very light ground the spade may be used; but it is far from being in much repute, excepting in such gardening operations as cannot well be accomplished with the spud.

I believe, but am not certain, that the Potato-fork, as it is called, had its origin in Ireland; but whether so or not, it is certainly to a stranger an implement easier to manage than the Kentish spud. In it three rather broad prongs, much shorter and more straight, are set into a head or handle of much the same description as the other, but it is altogether so much lighter that it is much easier to wield. Its use is widely diffused, and some of the stiff lands of Hertfordshire and adjoining counties are much easier turned over with it than with the spade. There are also many modifications of it, and of course various sizes. One, a sort of hybrid between a fork and the spade, has the tips of all its tines united to a plate having an edge like a spade. The advantage of this is strength, and in ground that sticks tenaciously to the tool there is less space for it to do so, and it delivers its load more readily. It, however, requires the same amount of force to induce it to enter the ground as the spade, and, not possessing some of the advantages of that tool, is not much used; but the ordinary three-tined digging-fork is in general repute in most of the midland counties, and is unquestionably a useful article.

The more-recently-introduced steel digging-forks, by some of the best implement-makers, are unquestionably making their way, from being adopted by spirited individuals in various districts. They are generally four-tined, and when made of good steel and not too slight they work very freely, clearing themselves well. Some of them, however, appear to be too weak for the stiff heavy lands, or to do such stubborn work as trenching and the like, but no doubt a stouter article can be had; while to the amateur, who likes a tool that will enter the ground easily, is light to handle, and to which the wettest soil finds but little space to cling, the steel

digging-spud is unquestionably the best tool he can have; and since most ironmongers keep them, it is easy to obtain them anywhere.

Some other forms of the articles above named might be mentioned, but I do not consider it necessary. We will, therefore, at once proceed to the implement which gives a name to all the usual modes of hand-tillage—the Spade; and though great diversity once did exist in this useful tool, there is certainly less variety now than of yore. A knowledge of the correct modes by which power can be applied to the best advantage has led to the abandonment of unsuitable articles; while the greater attention paid to the manufacture has caused considerable improvement, not so much in the shape as in the quality of the implement. It may be had of all sizes that may be wanted. Some little peculiarities to suit the customs of certain districts exist; but in general these are not important, and the names of some of the best makers may be favourites in districts hundreds of miles apart.

In the northern counties the spade is in more general repute than any of the species of fork with which we are acquainted, yet it is difficult to account for this. There is plenty of stiff land there, but custom has established the spade, and time alone will assert the claims of the fork if it be superior. For many purposes, however, the spade is indispensable. In digging up turf land, casting out furrows, or draining, the fork is powerless; but for draining or excavating operations there are other tools than the spade. One locally called the graft—in some respects like a spade, but the two sides curved in spout fashion—is a very handy tool for excavating in stiff ground, the load it lifts not being so likely to drop on its way to the cart or elsewhere as from the ordinary spade; but as the present article was to be confined to tools adapted for tillage purposes only, such tools need not be adverted to, as the graft is certainly inferior to the spade for that purpose.

As to the best makers of spades there are many different opinions. Lyndon's are in most repute here. In these the blade or edge seems to be of good steel, the handle-socket long, and there are side-straps to prevent it wearing at the neck (many other makes also have this), and the top cross-handle has a rivet through it to prevent its breaking as many do that are subjected to severe work. Working men, however, have all their especial favourites, and doubtless they are the best judges, especially after they have had trial of others. Certainly no article deserves greater attention on the part of the maker than the spade; and although price very often indicates quality, I by no means wish it to be inferred that a low-priced one is cheap. On the contrary, a well-made spade is easier to work with than an inferior one, and often lasts double the time, independent of the greater pleasure and comfort there is in using it. We find, however, that, useful as the spade may be—and there seems no reason to doubt of its continuing so with all the appliances of machinery and other inventions—there is nevertheless a limit to its use as well as that of all other things. Other tools require attention also; and leaving the further prosecution of hand-tillage to other parties, a few notes on various implements in general use may be given in future articles.

J. ROBSON.

PEAS. AND HOW TO GROW THEM.

(Continued from page 487.)

2ND. IN MODERATE-SIZED GARDENS.—In some places there is the convenience of a south wall. Under it, on the southern side, you can have Lettuce planted to come in after the Endive is done, and a row of Peas about 4 feet from the wall in a parallel line to it, without injuring the Apricot and Peach trees on the wall. Peas in this position should be sown on November the 10th, and from this parallel line let fall in December some perpendicular drills 3 feet apart, and sow in them Sangster's No. 1, Dillistone's Early Prolific being sown in the parallel. A few spruce branches will save these from the nipping east winds if stuck on one side of them. In open weather another sowing may be made in February, and on the 1st of March a sowing of Warwick (Early Frame, or whatever else the seedsmen please to call it), and Early Green Marrow. Whenever the first crop of

Marrows is sown it must be done at the same time that the last crop of earlies is sown. This is to provide for a succession. For successional crops the annexed table may be referred to.

After the first sowings are accommodated with warm sunny sites the main crops will do better in the open quarters.

Of late, planting Peas amongst other crops has been advocated. I am persuaded this is erroneous. I cannot tell what space is saved, nor see any better crops accrue, nor yet any crop that likes smothering between Pea-rows. I object to making Beet, Potatoes, and other root crops subservient to Peas. Suppose we sow Peas in rows 12 feet instead of 6 feet apart, and take a crop of Beet between, the Peas will take up 3 feet of the space, and of the remaining 9 feet fully 6 feet will not have any sun until ten o'clock, and none after three o'clock, so that there are but 3 feet left fully exposed to the sun's rays, and instead of its being a saving it is a loss of 6 feet. The Peas will be better for this extra space I admit—they will bear better if gales keep away; but when they are growing at wide distances they are more liable to be broken in a gale, and the few extra Peas gained do not compensate for the waste of ground. A gardener with a row of Peas here and another there will find himself in the same predicament as he that fills his garden with fruit trees and expects to grow vegetables under them. The height which any variety of Pea attains is ample distance between the rows of that variety, and the shade they afford to Celery during the hot dry months of July and August is beneficial rather than detrimental. Shade retains moisture in the soil, and that is a point worth courting in Celery-culture, especially where there are not those who can be always running about with the watering-pot.

Sandy or light soils do not afford good Peas in dry weather, and the Peas grown there are more liable to mildew, and are not half so sweet as those grown on richer soil—in fact, they are more like the bullet-like Peas bought in the market than fresh-gathered home-grown Peas. To obviate this sow on a manured trench similar to Celery, and give a drenching—dribblings are injurious—of weak liquid manure once or twice a-week, according to the weather. If it be warmed to 80° or 90° it will be the better; but if taken out of the tank where it has been diluted with spring water at a temperature of 50° it will check rather than forward the crop.

A row of Peas 20 yards long will afford from six to twelve pecks of Peas, and successional rows of that length sown every ten days will insure a supply for a family from June to November.

3RD. IN LARGE GARDENS.—South walls are here with frames, and glass houses without number. A row of Tom Thumb, Beck's Gem, or any other name you please (we want a sweeping-out of names, and a shorter nomenclature), sown along a south wall, and about a foot from it, about the 15th of October, will outstrip those sown anywhere else; and if a few spruce branches are stuck in front of them in severe weather, and the wall protected by nets, Peas may be had in May. The late Mr. Smithers, gardener to the late Sir Wm. Milner, Bart. and his father, for fifty-four years, of Nun Appleton, Tadcaster, informed me that he once gathered the Early May on the 13th of May, and in looking over his note-book I found a confirmation of the fact. To this old gardener I am indebted for much information; and his observations, extending as they did over half a century, gave one an insight into gardening matters from 1797 with certainty. I only regret not making more copious extracts.

I shall not say more about Peas in large gardens except a few notes on growing them in frames, houses, and pots.

Peas, where there is every modern appliance, can be had pretty nearly all the year. Tom Thumb is the best for pots, Eclipse and Sangster's No. 1 for frames and sowing in houses. The Pea is impatient of fire heat. A temperature of 40° at the beginning is hot enough, and a mean of 45° should not be exceeded until the Peas are in flower, when the temperature may be increased to 50°. They require abundance of light—cannot, in fact, have too much—and a current of air blowing on them continually.

To have Peas on New Year's-day a pit with a hot-water pipe or two is almost necessary, though they can be had in pots. When grouse arrive for table (12th of August), it is high time to sow a couple of rows of Peas in a six-foot pit:

Sangster's No. 1 at the back and Eclipse in front, 3 feet from the glass, in a soil rather poor, and a foot deep. Expose, taking off the lights, to the full sun and air, watering if necessary, and not putting on the lights until heavy rains and strong frosts render them necessary; but always take them off again when the weather is dry and mild. If all be well, little fire will be required, but if the Peas are not in bloom in the latter part of October fire heat must be applied, allowing a current of air to blow through the Peas day and night; even during fog, frost, and snow, air must be given. If the autumn be hot they may need retarding: a shading with mats after flowering will keep them back, and liberal supplies of water will keep them cool, and help to fill the pods. This crop will, if all go on right, afford a dish on Christmas-day, New Year's-day, and now and then throughout January. The pit should be 30 feet long to do this.

In another pit Peas should be sown on the 1st of September, this time using Tom Thumb, and they will afford a few Peas at the beginning of March, but not if the lights are half wood, and the other half opaque through age. Tom Thumb may be sown again on the 1st of October, November, and December in pits as before, after which Sangster's and Eclipse will do better, and two sowings of these are enough, on the 1st of January and 1st of February. The latter sowing will give Peas in May, and those on the south-wall border will follow them.

The late Peas being liable to be cut off by early frosts, and being difficult to cover up, a sowing of the early kinds made under the shelter of a wall in July where they can readily be covered up, or in frames, will pretty nearly enable the gardener to have Peas all the year round; but they are had at such a cost and in so small a quantity that few can indulge in them. Luxuries, however, are not measured by cost.

Pots 9 inches in diameter are best for Peas. Good drainage and rich porous soil are requisite. Fill the pots three-parts full with soil, and place the Peas all over the surface an inch apart. Cover thinly with light soil, half an inch deep or so; watering when necessary, and when the plants are 3 or 4 inches high earth them a little, and place some fir twigs round the sides of the pots. In all stages they must have abundance of air and light. If confined they become drawn, and attacked by green fly; if hot and dry, thrips and red spider will soon end them; and if kept in a cold, moist, confined atmosphere, mildew will paralyse them. Thirty pots sown on the 1st of September will give a dish of Peas on New Year's-day, if the pots are placed by a south wall, and not housed until the weather render it imperative necessary.

A few sown about the 1st of August, kept out of doors until frost comes, and then moved to an orchard-house, will afford Peas in November. Sowings can be made in October, November, December, January, and February, and those being in pots can readily be moved about from one house to another as their wants may render desirable. A row sown in an orchard-house will give Peas in the beginning of May if sown in October, and protected with a little dry coarse hay strewn over them in severe weather.

The months in which Peas are obtained with most difficulty are February, March, and April. To have them in the other months is merely a question of time, labour, expense, and appliance or convenience. One point more and I have done. In cold soils, and bleak and wet situations, it is a mere waste of seed sowing Peas in November. It is better to sow on reversed turfs 6 inches wide—3 inches will do—making a hollow in the centre lengthwise, and then sowing the Peas in the hollow, and covering with soil. A sowing made in this manner in February, brought forward in a vinery until the plants are a couple of inches high, and then removed to an orchard-house, pit, or frame, where they can remain until the beginning of April, when they will be hardened so as to bear planting out, will succeed better than rows that have stood the winter. I do not know who was the first to introduce the system, but he who he may be certainly deserves honourable mention.

Sowing Peas in pots to plant out is a good practice—in fact, a few hundreds of pots sown in February under glass, and the plants gradually hardened-off, often afford more Peas, continuing longer in bearing, and giving larger pods than Peas autumn-sown.

The following list includes the best varieties, and the length of time each variety takes to mature, all the varieties being sown at one period—the 20th of March. The dates refer to the time most conducive to their well-doing, or necessary to secure a supply.

Name and Description.	Time of sowing.	Weeks required to mature.	Height in feet.
SECTION I.—EARLIEST VARIETIES.			
TOM THUMB (Beck's Gem, or Royal Dwarf).—Very early, dwarf, useful for pots, growing in frames, and in warm situations.	Nov. 10th under a wall. January.	11	1 to 1½
DILLISTON'S EARLY PACIFIC .—Blossoms in a mass, pods small, all the crop gathered at once. The earliest Pea in cultivation.	Nov. 10th.	11	2
SANGSTER'S NO. 1 (Sutton's Early, Conqueror, Champion, & Daniel O'Rourke).—The best of the earliest.	Nov. 10th. Feb. and Mar. 10th	12	3 to 4
EARLY FRAME (Double-blossomed Frame, Charlton, Hotspur, Warwick).—Good cropper; stands severe weather well.	Nov. 10th. March 1st	13	5
SECTION II.—SECOND EARLY.			
<i>Coming into use in June and July.</i>			
DICKSON'S FAVOURITE (Auvergne, Sieble).—Extra long pods, containing nine to ten Peas. Fine flavour.	March 1st, 10th, 21st, & April 1st	14	4 to 5
BISHOP'S DWARF .—Large pods, good cropper and quality.	March 1st to April 15th.	13 to 14	3
PARADISE MARROW (Champion of Paris, Excelsior).—Good cropper and excellent flavour.	March and April.	14	5
CLIMAX (Napoleon).—Blue wrinkled Marrow; requires rich soil.	Mar. 15th to April 15th	13	3
BURKEDGE'S ECLIPSE (Stubbs's Blue Marrow).—Rich-flavoured large Pea; long pods, dwarf, robust-growing.	March and April. June 15th	14	3
BELLAMY'S EARLY GREEN MARROW (Prize-taker).—Great bearer, pods good size, Peas dark green. Keeps long in season.	March and April.	14	4
FLACK'S IMPERIAL VICTORY .—Branching, fine flavour, and good cropper.	April and May.	14 to 15	2 to 4
CHAMPION OF ENGLAND .—Most delicious; good bearer.	April and May.	14	5
SECTION III.—GENERAL CROP.			
BLUE PRUSSIAN (Prolific).—Round, prolific; excellent flavour.	April and May.	15	3 to 4
SCIMITAR (similar to Bedman's Imperial and Flack's Victory).—Round blue pods, long and curved.	April and May.	15 to 16	3 to 4
FAIRBEARD'S BLUE SURPRISE .—Long well-filled pods, containing seven to nine Peas; good quality.	April.	14 to 15	4
FAIRBEARD'S NONPAREIL .—White, wrinkled; good bearer.	April and May.	14 to 15	4
LORD RAGLAN .—Worthy of the veteran Marshal. Green-wrinkled, fine flavour; keeps long in season.	April and May.	17	5 to 6
THURSTONE'S RELIANCE (Dancer's Monastery).—Large and good.	April and May.	16	6
VEITCH'S PERFECTION .—Delicious flavour, robust branching habit, fine foliage, large well-filled pods. A better Pea cannot be.	April 1st to May 30th	16	3
WOODROSE GREEN MARROW (Nonsuch).—Rich flavour and productive; liable to mildew.	April and May.	15	3 to 4
SECTION IV.—LATE CROP.			
BRITISH QUEEN (Defiance, Carter's Victoria, Tall Mammoth).—Fine flavour, very large Peas and pods; bears till killed by frost.	April 15th to May 31st.	17	6 to 8
NE PLUS ULTRA (Jeyes' and Payne's Conqueror, Incomparable).—Deep green, great bearer, very superior flavour; best for late crop. Will not bear cold and wet.	May 1st to June 1st.	17	6 to 8
GENEAL WYNDHAM .—First-class; glossy, dark green pods.	April 15th to June.	17	6 to 7
VICTORIA MARROW (Waterloo, Gibb's Defiance).—Fine flavour, large pods, abundant bearer.	April 1st to May 30th	16	6 to 7
MAMMOTH DWARF GREEN MARROW .—Strong, dwarf habit, branching from near the ground; fine flavour.	May.	16	2½ to 3
MAMMOTH TALL GREEN MARROW (Monarch, Strathmore Hero).—Fine flavour, very prolific; large size.	April 15th to May 30th	16 to 17	6 to 7
MAMMOTH TALL WHITE MARROW (Champion of Scotland).—Sp eddied Pea; fine cropper.	April 15th to June 1st.	16 to 17	6 to 8
WHITE SCIMITAR (Sugar Pea).—Earliest; pods; the best of Haricots.	April and May.	15	3 to 4

Palates vary more than the quality of Peas. The best way to test Peas is to sow a small quantity of each, and so suit the appetite, and learn the kinds best adapted to the

soil and climate. It will prove an interesting experiment, and the notes accruing therefrom would be extremely useful.—G. A.

THE NATIONAL ROSE SHOW.

SECOND NOTICE.

So far as the two Metropolitan Rose Shows are concerned this year, my own judgment upon them was that while Roses were not out of character, they were certainly not in character. They were not, as two years ago, so badly bloomed that it was difficult to tell the varieties; neither, on the other hand, were they so fine as I have seen them, or perhaps as they will be at the Birmingham Show next week. As I said in the last JOURNAL OF HORTICULTURE, they had a "used-up" look about them; this referring to their general appearance, some blooms, however, being very fine.

Amateurs were certainly first, their flowers exhibited in some of their boxes being very fine; and, as in the account I gave of the Crystal Palace Show, I rather inclined to the nurserymen, I must now speak more of the amateurs; and here, as usual, Mr. Hedge, of Reed Hall, Colchester, carried the greatest weight of honours. Three first prizes and a second clearly testified to the immense difficulty of attempting to vanquish so experienced and so large a grower as he is. It is astonishing, and would be to those who are non-exhibitors, I have no doubt, almost incredible, how many trees must be gone over before a good box of blooms can be cut. I was talking at the Exhibition to one of the largest growers in the Kingdom, who was describing to me a magnificent quarter of Roses containing about 15,000 plants, budded with only one bud, and yet he said if he had had to cut ninety-six blooms he would have been greatly puzzled to have done it. Mr. Hedge grows about 2500 plants, and must do them well and creditably to be able to cut so many blooms so constantly as he does during the Rose season.

In the class for forty-eight Roses, single trusses, Mr. Hedge had Comtesse de Chabillant, Madame Furtado, Madame Vidot, Charles Lawson, Adam, Gloire de Santenay, Mathurin, Regnier, François Lacharme, Rubens (Tea, a most lovely bloom), Lord Raglan, Dr. Daultin, Madame de Cambacères, Souvenir d'Elise (Tea, exquisite), Jules Margottin, L'Enfant Trouvé, very fine—how any one can say this is the same as Elise Sauvage puzzles me; Madame Zoutman, La Ville de St. Denis, Madame Domage, Acidalie, Baronne Levest, Souvenir d'un Ami (Tea), Letitia, Prince Léon, Triomphe de Rennes, John Hopper (exquisite), Leo X., La Fontaine, Madame Sertot (Tea, good), Queen Victoria, Général Jacqueminot, Enfant de Lyon, Sénateur Vaisse, Colonel de Rougemont, Souvenir de Leveson Gower, Gloire de Dijon, Boule de Nanteuil, Auguste Mié, Madame Masson, Mrs. Blais, and Anna de Diesbach. Miss Crawshaw, Reading, was second. The most remarkable flowers in her stand were Madame Falcot (one of the highest-coloured yellow Tea Roses we have), Sénateur Vaisse, Gloire de Santenay, Amiral Mirvina, Baron Gondla, Devoniensis (very fine) and Madame Vidot. Mr. Worthington was third. In his stand was a splendid bloom of Isabella Gray (which, alas! too many displays her beauties), Devoniensis, Homer (a curiously mottled Tea), and Prince Camille de Rohan. In Mr. Ingle's stand, who came fourth, there was a beautiful bloom of the old yellow Provence, beautiful, indeed, but another of those which so rarely expand.

In the class for twenty-four blooms, Mr. Dobree, of the Priory, Wellington, Somerset, was first with Louis XIV., Comtesse de Chabillant, Jules Margottin, Queen Victoria, Gloire de Santenay, Moiret, François Lacharme, Louise Peyronney, Madame Masson, Madame Rivers, Madame Charles Crapelet, Gloire de Dijon, Lord Raglan, Madame Furtado, Charles Lefebvre, Caroline de Sansal, Madame Charles Wood, Souvenir de la Malmaison, Victor Verdier, Prince Camille de Rohan, La Reine, Sénateur Vaisse, and Louise de Savoie. Mr. Hedge was second, and in his stand were fine blooms of Mrs. Rivers, Comtesse de Chabillant, L'Enfant Trouvé, Charles Lawson, Gloire de Dijon, and Gloire de Santenay.

In the class for eighteens, Mr. Hedge was first with Madame Furtado, Madame Vidot, Lord Raglan, William Griffith, Madame de Cambacères, Souvenir d'un Ami, Ma-

dame Boll, Gloire de Dijon, François Lacharme, Juno, Madame Domage, Auguste Mié, Charles Lawson, Narcisse, Prince Regent, Comtesse de Chabillant, Monte Christo, and Caroline de Sansal. Mr. Ingle was second, and had, amongst others, good blooms of Devoniensis, Elise Sauvage, Pauline Lanzeleur, William Griffith, and Charles Lefebvre.

In the class for twelves, Mr. Hedge was again first with Charles Lawson, Madame Vidot, Gloire de Dijon, La Ville de St. Denis, Souvenir d'un Ami, Madame Boll, Caroline de Sansal, Madame Pierson, Mrs. Rivers, La Fontaine, Juno, and Lord Raglan. Rev. H. Helyar, of Yeovil, was second with Sénateur Vaisse, Général Jacqueminot, Madame Furtado, Victor Trouillard, Comtesse de Chabillant, Madame Hector Jacquin, Jules Margottin, Gloire de Dijon, Eugène Appert, Comte de Nanteuil, Triomphe de Paris, and Charles Lawson.

To enumerate the names of the winning flowers in each stand seems a repetition, tiresome, and endless. We also know what Roses to expect. Of course, Général Jacqueminot, Comtesse de Chabillant, Sénateur Vaisse, Gloire de Dijon, and other Roses of a similar well-known character will be there, and, therefore, as I am now to notice the nurserymen's prizes I will only take such flowers as were remarkable in each class. A flower may be in one stand excellent, in another worthless.

In Mr. Cant's stand of ninety-six, which obtained the first prize, were John Hopper, Céline Forestier, Comtesse de Kergorlay, Souvenir d'un Ami, Cloth of Gold, Christian Püttner, Alexandre Fontaine, Sénateur Vaisse, Olivier Delhomme, Madame C. Wood, Louis XIV., Eugène Appert, Souvenir de Comte Cavour, Souvenir d'Elise (a most exquisite bloom), Duc de Rohan, and Devoniensis. In Messrs. Paul & Son's stand, which obtained the second prize, were Louis XIV.; John Hopper, very fine; Madame C. Wood; Baron Rothschild (1862); François Premier; Jean Goujon (1862); Maurice Bernhardt; Aurora, good Tea; Lord Canning, fine; Madame Julie Daran; Monte Christo; Vicomte Vigier; Le Rhone (1862); Tronson Goubault; Anna Alexieff; Sénateur Vaisse; Prince Camille de Rohan, fine. In Mr. Mitchell's third were Louise de Savoie, Sénateur Vaisse, Charles Lefebvre, Professor Koch, Joséphine Maulton, Souvenir de Lady Eardley, Christian Püttner, Souvenir de Comte Cavour, Gloire de Dijon, Turenne, Général Jacqueminot, Duc d'Osuna, and Madame Charles Crapelet.

In the class of forty-eights, three trusses of each, Mr. Charles Turner, of Slough, was first with, amongst others, Madame Charles Crapelet, Céline Forestier, Souvenir de Comte Cavour, Général Jacqueminot, Paul Ricaut, François Arago, Caroline de Sansal, Narcisse, Comtesse de Chabillant, and John Waterer. In Mr. Francis's stand, which obtained second, I noticed Sénateur Vaisse, Gloire de Dijon, Paul Ricaut, Mdlle. Ponnaie, and Louis XIV.

In twenty-four trebles, Mr. Keynes, of Salisbury, was first. He had some fine blooms of Paul Dupuy, Evêque de Nîmes, Pauline Lanzeleur, Madame Vidot, Sénateur Vaisse, François Lacharme, Colonel de Rougemont, Prince Léon, Jules Margottin, and Olivier Delhomme.

In twenty-four singles, Mr. Charles Turner, who obtained first prize, had fine blooms of Madame Charles Crapelet, Anna de Diesbach, Devoniensis, Général Jacqueminot, Charles Lawson, Lord Raglan, Madame Vidot, Paul Ricaut, Jules Margottin, Charles Lefebvre, Anna Alexieff, Gloire de Dijon, Madame Hector Jacquin, Madame Boutin, Madame Willermoz, Mathurin Regnier, Vicomte Vigier, Victor Verdier, Madame Knorr, Madame Boll, Comte de Cavour, Souvenir de la Malmaison, and Sénateur Vaisse.

It was quite too late for pot Roses, but for the season some creditable plants were exhibited by Mr. Wm. Paul, and Messrs. Turner, Paul & Son, and Francis.

In the class for twelve blooms of any new Rose of 1862, Mr. Wm. Paul was first with Beauty of Waltham; and Mr. Cant second with Olivier Delhomme. A fine box of Tea-scented and Noisette Roses came from Mr. Hedge, comprising Boule d'Or (very fine), Madame William, Reine Victoria, L'Enfant Trouvé (fine), Bougère, Moiret, Madame Sertot, Souvenir d'un Ami, Madame Bravy, President, and L'Enfant de Lyon. Mr. William Paul was second, and Mr. Hollingworth third.

Moss Roses call for no particular remark, nothing either new or good was noticeable amongst them.

The adjudication for the decorated vases or baskets seemed to me and others very odd. The first prize was given to a stand which contained not one good Rose, and violated all the principles of taste by having a huge piece of coral on the top and shells on the bottom stand—it was one of Mr. March's stands. It seems to me that the Judges are perplexed between the stand and the flowers, but in neither case do I think the award was a correct one; and the worst of such awards is, that they perpetuate that very badness of taste they are intended to destroy. The group which obtained third prize was a magnificent bunch of fine Roses, such as any one might place on their table; whereas the first was one I should have scorned for mine. But I suppose one must only say, "*Chacun a son goût*;" but if the "*goût*" be bad it is unfortunate. Mr. Wilson Saunders' prize was won by *Cécile de Chabillant*; and in the class for six bouquets of Roses Mr. W. Paul was first with *Coupe d'Hébé*, *Senateur Vaisse*, *Madame Vidot*, *Prince Camille de Rohan*, *Charles Lefebvre*, and *Celine Forestier*.

I have thus noticed the more remarkable features of the Show of Roses, and may at some future time give the general result of my observations. I regret that circumstances hinder my being present this year at the Birmingham Show, which I contemplate will be the best of the three.

And so ends the Royal Horticultural Society's Exhibitions for 1863, in which it may safely be said that as noble collections have been exhibited as were ever brought together, but of which a great deal of the beauty was lost by the place of exhibition. It is, however, doomed; and let us hope that next year may witness some attempt at tasteful arrangement in a place more suitable for the display.—*D., Decl.*

CLIANTHUS DAMPIERI CULTURE.

THIS most exquisite plant is a native of New Holland, where it goes by the name of the *Glory Pca.* I have had many losses in trying to grow it, and probably I am not the only one who has suffered. Such being the case, these few remarks may assist some, who, like me, have a great love for this beautiful climber. Many a batch of seedlings I have lost after potting-off, but at last I had the pleasure of seeing it grow and bloom most gloriously.

The secret I consider lies in not injuring in the least the young roots, for in this respect it is the tenderest plant I ever handled. The seeds should, therefore, be sown singly in small pots, and placed in a gentle bottom heat; but they must be removed to a cooler place so soon as they have germinated. The seedlings should be shifted into a larger-sized pot before they have time to root to the side of the one in which they were sown, and when they have grown to some 5 or 6 inches in height, they should have their final shift either into a large pot, or be planted out in a greenhouse, and trained against a rafter. They will succeed either way, but if a suitable place can be found, I should prefer the latter.

The soil I find this plant thrive in is a good fibry loam, with a slight addition of dung, leaf mould, and silver sand. It requires plenty of drainage, and will take a liberal supply of water. It also requires strict watching in its young state, particularly to keep its greatest enemy, red spider, away; but it will amply repay by its splendour any amount of care bestowed during the two years of its existence.—*JUVENIS.*

A SURE WAY TO SUCCESS IN STRAWBERRY GROWING.

IN No. 116 of THE JOURNAL OF HORTICULTURE, page 432 there is an interesting answer from Mr. Robson to "A. Z." on the subject of Strawberry-growing. I am able to confirm all Mr. Robson says, and I will add a few simple directions which will enable any one to command success with Strawberries of all kinds, provided those directions are fairly carried out.

The plan, which I gave in THE COTTAGE GARDENER some years ago, is nothing more than this. About the second week in March place round each plant a heap of half-rotten stable-manure, and if any fresh droppings can be added to it before putting on so much the better. A small quantity scattered

round the plants is not sufficient, but enough should be placed round each plant to stand 8 or 9 inches high after being firmly pressed down with the hands; and the ring of manure thus pressed down should extend to about 10 inches all round. Of course the plants must be 20 inches apart at the least.

The time for doing this is about the second week in March; if it is done before, or during winter, the plants are likely to run too much to leaf; if later than March the benefit is lost. When the right time is taken advantage of the next rains wash the rich juices of the manure to the roots of the plants, and the mulching material which remains protects them from drought during the rest of the season.

I have had sixteen years' experience of this plan, and never yet failed in having a first-rate crop of all kinds of Strawberries, *British Queen* included. I never gave, and never shall give, a drop of water to a Strawberry plant. I find that a much smaller number of plants is sufficient to satisfy my wants for preserving, for Strawberry feasts, and for two large dishes a-day during the season, than would be necessary under any other system. In fact, I estimate the produce of each plant, except *British Queen*, which is rather less productive, at one good dish from first to last.

Now it is a very easy thing to give these directions, and very easy also to follow them, but it is quite another thing to find people willing to carry them out. One man will sprinkle only a little fresh litter round his plants; another will say it is altogether too much pains to bestow on each Strawberry plant. In such cases I never take the trouble to say anything more about it. I have the satisfaction of knowing, however, that those who have followed out this plan fairly were well pleased with the results.

Last year a friend from Lincolnshire paid me a visit, and admired my success with Strawberries. I gave him full directions for his gardener to follow, and told him that the only difficulty was to get them carried out. He said, "Oh, I will take care of that." This year, at the end of May, I paid him a visit in Lincolnshire, and the first thing I did the morning after my arrival was, of course, to inspect the gardens, and make friends with the gardener. He at once took me round his houses, and showed some very fine crops of Grapes in all degrees of forwardness; then I saw the Pine and Melon-pits full of magnificent fruit, and some of both ready to cut; from these we went to the orchard-house, where everything looked healthy and productive; and finally we strolled round the kitchen garden. I stopped opposite to some Strawberries, of which there evidently would not be a quarter of a crop, and said, "You won't have much of a crop this year." He replied, "No; we never get much of a crop in these parts; the soil does not seem to suit them." "Do you never mulch them?" I said. "Oh! I declare, I believe you are the gentleman that wanted master to put hens'-nests round the Strawberries." I confessed to the soft impeachment. "Ah!" his reply was, "that might answer all very well in some places, but we have such a lot of birds here that they'd be always pulling them down, and littering the garden about." I left him without alluding to the subject again. It was a hopeless affair. It never occurred to him to try and see whether his fears were well-grounded or not. I myself am pestered with thrushes and blackbirds, but I never saw any litter in my garden; they may pull one or at most two heaps about once in the season, but the gardener sets them right again in half a minute.

The remaining advantages of this plan, besides being independent of the season, are freedom from slugs and from the splashing of the berries with the soil during heavy rains; and Strawberries may be grown for many years upon the same ground without degenerating in any way. I have already kept one piece of ground under Strawberries for sixteen years without the slightest loss of either quality or quantity.

In conclusion, the sorts I recommend for cultivation are *British Queen*, which is by far the best of all; *Keens' Seedling*; *Filbert Pine*, an admirable Strawberry, and but little known, very excellent in flavour, and an astonishing bearer; and *Black Prince* for the early crop. For a late crop I prefer placing *Keens' Seedling* in a somewhat shaded and cool situation.

For greenhouse culture the *Black Prince* is by far the best. Of course the plants should be placed close to the glass;

and if they are treated with plenty of manure water, and stand in saucers, they may be depended upon to produce a good dish for every four pots. They come in five or six weeks before the out-door plants, and last until these are ripe.

If any one, like your correspondent "A. Z." finds that he cannot make his Strawberry plants bear under ordinary treatment, let him try the method I have described, and I assure him he will not be disappointed even with plants of the first year. By the way, Strawberry plants should always be struck in small pots, and planted out, if possible, in August; a bad winter and spring will show the importance of this.—H. C. K., — *Rectory, Hereford.*

CUTTING-DOWN CANON HALL MUSCAT VINE.

MR. FISH some time ago startled the readers of this Journal by announcing that he had seen some very flourishing Vines during his visit to Ireland that had been sawn off but recently at the stem's junction with the root. On the evening of the 24th June I called on a friend, Mr. D. Ackroyd, gardener to L. Nathan, Esq., West Lodge, Bradford, and very soon stumbled on a Canon Hall Vine. We had so often seen this Vine with large bunches badly set and three parts of the berries ruined by the spot, that we felt indignant at the idea of growing Muscats along with other Vines requiring a cooler temperature; but now the Vine was so much altered in appearance that we could not believe it was the same. Having satisfied myself on this point—for the Vine was cut down about three years ago—I gleaned the following information from the intelligent and persevering gardener:—

"In November of last year the roots (three in number) were cut off 1 foot below the surface—that is, the Vine had only three bare stem-like roots without fibres, 1 foot long each, left. A little of the old soil was taken away, but very little, not more than a barrowful, and three bushels of coconut refuse put in the hole. In this the stubbed-up Vine was planted, and the ordinary soil of the border thrown on so as to level the whole neatly. There were other Vines in the border, so that it was impracticable to make a large hole. Shortly after this was done 1 foot of stable litter was put upon the border, and that, as might be expected, heated very little indeed. The house was started in the beginning of February, and ripe Grapes were cut on the 14th of June. The Canon Hall broke as well as any of the other Vines, never flagged under the brightest sun, the flowers set well, and the whole progressed extremely well. It had the same heat and treatment as the other Vines, and the result is as follows:—Length of fruiting portion of cane, 10 feet. (It was not headed down, but left its full length in the ordinary course of pruning.) The young leader is $1\frac{1}{2}$ inch in circumference, with round plump eyes. There are nine good-sized bunches on the Vine, the majority being 9 to 10 inches long, $10\frac{1}{2}$ inches across the shoulders, and the berries, remarkable for their evenness of size, measure 3 to $3\frac{1}{4}$ inches in circumference, either round by the footstalk or the middle of the berry. They are just beginning to ripen, and will, of course, be larger yet."

In the same house—in fact, the onlyinery—I noticed a companion Vine that had been inarched last year. The stock was an old Barbarossa that never did well, the scion flowered Muscat, and the operation has resulted in seven good-sized bunches, and wood promising well for another year.

The other Vines were in capital order, a St. Peter's having nearly thirty large bunches upon it, and better set and finer-shaped bunches I have not seen. A Tokay was bearing freely, Hamburgs were fast approaching maturity, and a kind here called Victoria Hamburg was very fine. It much resembles, if it is not identical with, Pope's Hamburg; but, if anything, with a little more of the Esperione about it. It is a more compact buncher than the old Hamburg, more even in the berry, forms large shoulders, and is in every way a desirable variety. Notwithstanding that this is the only house set apart for Grapes, yet, with a proper admixture of sorts, fruit is had late in the season. The Sweetwaters are ripe now (June), Hamburgs will follow, then come Muscats and Tokays, and, last of all, the St. Peter's.

Under the Vines were Cucumbers in pots, with fruit nearly 2 feet long, and plants and Ferns too numerous to mention. The conservatory was neatly arranged, and gay with flowering plants. In a pit I observed some nice plants, as *Nepenthes distillatoria*, with a profusion of pitchers; *Ixora javanica*, *I. coccinea superba*; a good plant of *Pandanus javanicus foliis variegatis*; *Alocasia metallica*; *Alocasia macrorrhiza variegata* (small); *Allamanda Schottii*, *cathartica*, *nerifolia*, &c.; *Dipladenia crassinoda*, *Crotons variegatum*, *pietum*, and *longifolium variegatum*; *Vincas rosea* and *rosea alba*, *V. ocellata*; *Cyanophyllum magnificum*; *Cyrtoceras reflexa*; *Caladiums Chantini*, *Wightii*, *argyrites*, *Belleyneii*, &c. In another house were a magnificent specimen of *Pavetta borbonica*; a fine specimen of the finest of all fine-foliaged or variegated plants, *Cissus discolor*; *Sphaerostema mammosa*, a poor thing under any circumstances, and it was as fine here as I have seen it; fine plants of *Stephanotis floribunda*, *Hedychiums*, &c., all of which are generally considered to belong to fine places where there are acres of glass and scores of hands. Never was a more mistaken idea. It is brains and a patient, dogged, and persevering will that can grow such in a small place. There are a neat lawn and flower-garden all in good trim.

I must not forget to say that last year Mr. Ackroyd took several prizes at the Bradford Show for plants, and the first prize for the best dish and largest bunch of Grapes. He yearly gets some fine Mushrooms out of his Melon-pits in winter, and all he does is to put a little spawn on the manure before the beds are earthen. Last winter he had them in frost and snow without any covering but the lights, and a specimen weighed 1 lb. I think he would willingly let any gardener see the Vine in question, and answer any inquiries respecting it.—G. A.

GARDENERS' FRIENDLY SOCIETY.

LIKE our friend of the Green Isle, who last week favoured us with a reminder in relation to the proposed Gardeners' Benefit Society, I have been expecting to hear week after week that the scheme had taken some definite form, and I have been surprised at the continued silence respecting it. I believe I have shown on a previous occasion that my views were in favour of the project, although I might have failed to state clearly that I would become a member, provided the proposed Society actually came into existence.

Why gardeners as a body have not come forward and supported the motion, as doubtless would have been the case with men of other callings, may appear inexplicable; but the fact is gardeners are not constantly together as men of other trades are; the nature of their business keeps them far apart; they meet very rarely in a body; the means offered for anything like social gatherings are few, and but a minority of them do or can take advantage of horticultural societies for the purpose of holding friendly intercourse, so that horticultural journals offer the only ready means of their communicating with each other. This means is far from being likely to excite or maintain an interest in any undertaking equal to that which is kept alive by personal intercourse in the case of men who follow their ordinary occupation in bodies; nor do I believe that the ordinary wages of gardeners are sufficient to induce them to be particularly provident, and at the same time maintain that respectability in appearance which seems to be required of them. In this respect I think there is still room for improvement, which probably will be accomplished when gardeners—that is, the average run of them, enter more deeply into the mysteries of their calling. How this may be remains to be seen; but a grand step will be taken in the formation of a general Gardeners' Society like that formerly proposed, and which I now advocate.—F. CHITTY.

CYANOPHYLLUM MAGNIFICUM.—In your Journal of June 23rd I saw an account of "A YOUNG GARDENER" having a *Cyanophyllum magnificum*, some of the leaves of which measured 26 inches long and 13 broad, and I was rather surprised at the note of the Editors, remarking that they had never seen one with leaves so large. Fancying mine were usually larger I went with my gardener and we measured

two of the leaves, one of which we found to be 32½ inches long and 19 broad, the others 33½ long but not quite so broad. Consequently I presume my mode of treatment must be even better than that of "A YOUNG GARDENER," and if it be worth having I shall be happy to impart it. —AN OLD GARDENER (AMATEUR.)

HAYBANDS ROUND ROSE STOCKS.

PERHAPS it may be of service to many of your readers who have Roses worked on half or tail stocks of the Manetti to mention a plan which I have found to succeed admirably.

I noticed this morning that a few Roses which I had worked on Manetti stocks at about half height looked very sickly. They broke feebly, and their leaves were much spotted. It occurred to me that as the Manetti answers well as a stock if it be covered with the soil, it might also answer if the stocks were covered so as to keep them damp and in the dark. Accordingly I had all my Manetti stocks wrapped round with small hay-ropes, which in dry weather are moistened every morning. This plan has been quite a success. The Roses have thrown out stronger shoots than they ever made since they were budded, and have become healthy and vigorous. But one of them—Général Jacqueminot—has blown as yet, and its flowers have been very fine indeed, much better than it ever bore before. Of course, no one would now bud on Manetti stocks; but any person who did so in years past may find my experience useful.

May I add that having a nice stock in which a bud of 1861 had failed last summer, and not wishing to lose it, I tied a piece of list around it, and kept it moist for about a month? At the end of that time the bark had become green, and rose so freely that I inserted a bud, which is now showing flower.—S. M.

THE STAMFORD HORTICULTURAL PETE AND ROSE SHOW.—JULY 8TH.

THE show of Roses was especially good; indeed, it was generally admitted to be superior, in point of quality, to any Show of the kind held this season, not excepting the Kensington one; and it was so because the very best date that could have been selected according to the season was that upon which the Exhibition was held, for out-door grown Teas could be cut so as to be worthy of being staged alongside of their hardier compeers.

When we mention the names of Mr. W. Paul, Mr. Francis of Hertford, Mr. Cant, Messrs. Paul & Son, Rev. S. Reynolds Hole, and others as being amongst the competitors, a fair idea may be formed of the Show's importance; and its extent will be understood when we state that the number of competitors was fifty, staging at least 1400 trusses. The day was happily of the brightest, and everything was done to contribute to the enjoyment of the numerous visitors who thronged in from a distance. Two military bands played alternately, and the whole arrangements were based upon those at the gardens of the Royal Horticultural Society.

But we will now proceed to notice the main features of the Show, and in doing so we shall only name the principal prizetakers, &c., as it is obviously not sufficiently interesting to the general reader to give the whole in detail, when the list comprises within its bounds some eighty-six distinct prizes.

The prizes for cut Roses, forty-eight varieties, three trusses of each, were severely contested, and, indeed, this was the case in every class set aside for cut flowers. Mr. W. Paul showed Maurice Bernhardt, very fine, a Rose of fine form, slightly imbricated, and in colour beautiful vermilion; Mr. Francis, of Hertford, Madame Rivers (which, though not fine in colour, is well formed), Senateur Vaisse, and Lord Raglan; whilst Messrs. Paul & Son had fine specimens of Duc de Rohan (red, shaded with vermilion), and François Lacharme (bright varying carmine). Mr. B. R. Cant, of Colchester, had, conspicuous among many good ones, Alphonse Damazin, very deep glowing crimson.

In twenty-four, three trusses of each (Nurserymen). Mr. Draycott had Senateur Vaisse, a magnificent Rose; whilst Mr. Batley, nurseryman, Rugby, showed a fine stand; they

had the merit of not being so open and starry as some others in the class—here were Comtesse Chabillant (a beautiful Rose), Madame Rivers (generally good), Léon des Combats (splendid Rose, double crimson), &c. We should not omit, however, Charles Lawson, which is a remarkably fine Rose.

In collections of new Roses, there was a very close competition amongst those who showed in this class. Though Mr. W. Paul was second, we were greatly struck with the merits of his collection; but, owing to the many fair admirers of these noble flowers who incessantly flocked around these stands, we could not, without laying ourselves open to a charge of rudeness, advance sufficiently near to enter more directly into their various merits, or even take notes upon the same.

For the best twelve of any one kind, Mr. B. R. Cant, of Colchester, was first with Madame Furtado, rosy crimson; good. Second, Mr. E. P. Francis, of Hertford.

For the best twelve of any one kind of 1862, Beauty of Waltham carried off the first prize. No question can be raised, we think, as to the quality of this Rose, and, as compared with the drawing of it by Mr. Andrews, its colour is certainly better even than that given it by the artist.

In twenty-fours (Amateurs), the Rev. S. Reynolds Hole, Mr. Hunt, of Leicester, and Thos. Laxton, Esq., were the most successful competitors. It would be but a repetition to instance the many good trusses shown. Great credit was certainly due to Mr. Laxton, who, with a dusty suburban villa garden, exhibited successfully where seven competitors had staged; giving but another proof that success is ever an attendant on perseverance.

Amongst Exotic Ferns, Mr. Almey stood conspicuous. We noted especially fine plants of the evergreen *Platyloma rotundifolia*: the not-generally-grown, though useful, so-called *Platyloma adiantoides*—fronds longer, with the individual pinnae smaller than the old *Cassebeera hastata*.

In Fuchsias, Mr. Russell was first with some very excellent examples of cultivation. His plants, unlike the huge metropolitan ones, were as wide at the base where they overhung the pot as they were high, and exceedingly well bloomed. The better sorts were Little Bo-peep, Guiding Star, General Williams, Pearl of England, and Cœur de Léon.

Caladiums were ably represented by Messrs. Wood and Ingram showing a very fine plant of the unique *Belleynei*, white variegated slightly with green. We never saw the purple tint habitual in the leaves of this so prominently brought out. Could it have been grown in sun?

Begonias from Mr. R. Austen were fair samples of good cultivation. One called Marshalli, in the collection, we could not distinguish from the even more handsome old Rex. Madam Walter Butt shone conspicuous with its uniformly silvered foliage.

Roses in pots were very inferior.

Amongst some well-grown *Achimenes* by Mr. Russell, we noticed a fine purple.

The prize for newly-introduced plants was taken by Mr. Brown, for *Caladium Veitchii*, which, having but one large leaf standing conspicuously, put one in mind, to use a passing observation we heard a lady make, of the animal which Absalom bestrode in his anger. Messrs. Wood & Ingram exhibited a small plant of *Caladium Lowii*. From Mr. Brown came *Gloxinias*. The Marquis de St. Innocent, a pale colourless variety, was singular.

Some very creditably-grown *Cockscombs* were exhibited by Mr. Thompson, of Stamford. This gentleman's productions, not a few, were very creditable taken as a whole.

A device in flower-beds made upon an elevated platform with cut flowers in colours, gravel walks being ingeniously represented with mustard seed, a grotto and playing-fountain being attached, was very interesting. Amongst the plants around the fountain was an exceedingly pretty variegated variety of *Kalosanthes* or some kindred plant, not unlike the *Echeveria retusa* in form, becoming with age elongated upon a stalk which loses its foliage, beautifully variegated with gold, and just the plant for a Warden case or other place where pleasing and singular foliage is in requisition. Messrs. Walters, the successful exhibitors of the above, knew no name for it.

TABLE DECORATIONS.—Three prizes were here offered for groups of fruit and flowers for the decoration of the dinner-

table, based upon the regulations in practice with Sir Wentworth Dilke's prizes at Kensington. We cannot attempt to criticise this; suffice it to say, that in no one instance were either birds, beasts, or fishes exhibited.

[Our reporter having taken the first prize is the reason for his silence. We extract the following from the *Lincolnshire Express*:—"That showed by Mr. W. Earley, gardener to F. Pryor, Esq., of Digswell, Welwyn, was an excellent specimen of art, and secured the first prize. Mrs. Walker, of Stamford, obtained the second prize. This lady's design was exceedingly pretty, the top consisting of three cornucopias combined, containing Cherries, Grapes, and Strawberries. Mrs. Jos. Phillips exhibited a vase of flowers which for elegance and taste displayed in the arrangement was unequalled. The prizes for the groups of flowers, &c., were awarded by a jury of ladies. There was also exhibited in this tent a very attractive bouquet of artificial flowers, constructed by Eliza Mary Hunt, of Burley-on-the-Hill, who has been an invalid from childhood."

For the same reasons we cannot pass any remarks upon hand-bouquets, &c., though each had classes and were well competed for.

FRUIT.—There were some good samples of fruit. Mr. Matheson, gardener to the Marchioness of Exeter, showed fine collections, as also two fine Black Hamburgh Vines in pots; the two when arched together counting at least twenty-four good-sized bunches. Mr. Bowman, gardener to John Hardy, Esq., Grantham, had exceedingly fine samples of the Golden Hamburgh Grape, good Black Hamburgh Grapes, and Green-fleshed Melon, with each of which he took the first prizes.

In conclusion too much cannot be said in praise of the uniform courtesy of the two Honorary Secretaries, Messrs. Laxton and Hewitt.—W. EARLEY, *Digswell*.

STUDLEY ROYAL.

STUDLEY ROYAL, near Ripon, Yorkshire, is the residence of Earl de Grey and Ripon. The pleasure grounds are celebrated for their beauty and extent, and by many are considered the finest of their kind extant. John Aislabie, Esq., a good old country gentleman, assisted by his gifted gardener, Mr. Fisher, formed the grounds at Studley Royal about the year 1720; and his successor William Aislabie, Esq., spent a long life in beautifying and extending what his father had founded.

The pleasure grounds are situated in a narrow deep dell, called the Skell, with steep, irregular, wood-covered sides, and traversed by a stream. The situation must have been very beautiful in its natural condition, and, consequently, required a tutored eye to bring it into its present improved picturesque state. The eye and mind must have been well acquainted with what forms a good landscape picture, and not only that but with the combinations which produce one. The proprietor as well as the gardener had, judging from the results of their efforts, a sound knowledge of pictorial effect. They were not forming a picture for themselves only, but one that time would improve and which now may be said to have attained the height of its beauty.

An adequate account of all that is worthy of note in these grounds would almost form a large volume; I must, therefore content myself with noticing a few of the principal features.

Arrived at the park lodge a noble avenue of Limes is entered, shutting out the view of the woodlands on each side; but at times a glimpse is caught of the many fine Oaks with which the park abounds, some of them girding 30 feet a foot above the ground, and a view of the mansion to the right. Midway in the park, turning to the left, along an avenue of Beech trees of stately growth, I presently came to the beautiful little valley of the Skell. To the left of the entrance to the grounds is a lake covering twelve acres, into which the water or stream from the grounds empties itself by a fall of about 6 feet. The fall is accompanied by a low turret balcony-wall, and on the lake were aquatic fowls, now and again uttering their peculiar cries. Ascending a steep bank from the lake, shaded by a canopy of Beech and Chestnut trees, the gates are reached.

The entrance to the grounds is by an iron gate with some

inadequate lodges by its side, where each visitor pays 1s. and enters his name in the visitors' book. Great and small do this; and as this nominal charge is applied to keeping in order grounds which contribute largely to the enjoyment of the public, no one can cavil at the sum, for very few people would like to keep at their own cost some hundreds of acres for the good of the manufacturing community. The kind and generous feeling of those who allow their grounds to be seen by the public, who for the most part are shut up week after week in the smoky, impure air of our large towns, cannot be too highly eulogised.

These grounds are open every day except Sunday, and guides are ready at the gates from seven o'clock in the morning until five in the evening, to conduct and point out interesting objects to the visitors.

Passing along a broad and comfortable walk carpeted by foliage and with a dense tall screen of Yew to the left, shutting out the view of the other side of the valley and the water in the hollow, yet with a few openings, embrasure-like, that reveal some of the beauties, a pleasing feature is reached. This is a steep bank planted with common Laurels pegged down so as to hide the whole of the ground, and kept about 2 feet high by cutting back the shoots once or twice during the summer.

Beech trees of large dimensions overshadow the walk; and as the eye catches a glimpse of an octagon tower situated on the opposite side of the valley a cast, said to be lead, of two contending gladiators near the water below, is seen. There is still a dense wall of Yew to the left and its canopy overhead, but an opening is reached that has taken many by surprise, being a prospect of the valley in its widest part. A little to the right stands a building called the Temple of Piety, well backed by the foliage of the trees of a neighbouring slope. Beneath is a level piece of ground, where the water from the upper part of the grounds is expanded into spaces of lake with accompanying statues of Neptune, Bacchus, and Galen.

A lover of fine trees can hardly pass some to the left that stand near glades of lawn sloping from the eye to the water edge. A Norway Spruce (*Abies excelsa*), near the walk, but somewhat entangled with the adjoining shrubs, is straight, without any apparent deviation to the top, and displays a luxuriance I have not seen elsewhere. It is 126 feet high, and the stem more than 12 feet in circumference above the roots. Another, nearer the stream and less enclosed by other trees, attracts readier attention: it is not, however, so lofty, and is but 11 feet in circumference of stem. A North American Spruce on the other side of the grassy opening to the Norway Spruce is 14 feet in circumference of stem, and 135 feet high. Almost adjoining stands a fine example of the Hemlock Spruce (*Abies canadensis*), 70 feet in height, with a stem nearly 8 feet in circumference. Supposing those trees to have been planted by Mr. Aislabie about 1720, a useful criterion of growth is furnished to subsequent planters of Conifers.

Passing on you begin descending the declivity under the shade, and perhaps, may see as much beauty in a Sycamore tree 70 feet high without a branch, as in a gorgeous flower parterre. Evergreens and groves adorn the declivity, and from a cavern a stream issues overshadowed by a dense mass of Beech foliage.

The eye scarcely loses sight of this before a view is gained across a bank of Yew and Laurel, overhung with noble foliage, of the long canal as it is called, the moon and crescent ponds, with their grassy terraces, and of the lake in the park, backed up with woodland scenery. The statues in the valley and an octagon tower to the right rising from a clump of Firs are also interesting objects.

Continuing my journey, I have another peep through the Laurels, and see the statues Hercules and Antæus in contention, in the narrowest part of the dell. Diverging to the left instead of following the path through the woods, but still overshadowed by old trees, I crossed to the other side of the valley by a rustic bridge, where the stream glides silently along. On the bank of an irregular pool called Quebec are several naturally-inarched trees, none of them being more than 15 inches in circumference of stem. On a small island in this water stands a monument to the memory of the gallant General Wolfe, and beyond I soon found myself in a formal yet beautiful valley, in which is a build-

ing called the Temple of Piety. Inside of this is a mural basso-relievo of the Roman female nourishing her captive father from her breast.

The view here is confined to the valley yet possessed of much peculiar beauty, but the scene suddenly changes. I passed up a steep path in the wood, but just stopped to make a note of an old Yew that is fast decaying and said to be 700 years old. It is only some 5 feet round, and how it came to be 700 years old without attaining the majestic proportions of its neighbours seems curious. Passing through a short subterranean passage partly hewn through rock the octagon tower is soon reached, and from it we have a view of the objects so recently visited; but seeing them again from another and distant point does not give the sameness one might expect.

Studley Hall to the north is seen from here; and in the opposite direction How Hill, with a mimic tower begirt with shade, is a conspicuous and interesting object. Leaving the octagon tower I passed a long but purposeless avenue of Beech trees, in no way improved by the sombre hues of Firs, which give an air of solemnity not desirable in pleasure grounds. I always deprecate avenues formed of deciduous trees and evergreens intermixed. Evergreens are formal, lack gracefulness, and though noble-looking, are seldom majestic; and such mixed avenues are less harmonious than those composed exclusively of deciduous trees. Conifers contrast best with formal landscape work, as in gardens where oriental fashions predominate, and they are more adapted to back-up and relieve statuary and the dazzling Italian or geometrical flower parterres than to plant with deciduous trees in avenues or groups. Cedars are well enough for an avenue leading to a mausoleum, but in a richly wooded district they are too formal. They are more fitted for a hill top or a mountain side than to plant in right lines. Pursuing the ample path I was delighted with an aisle of Beech trees; but an opening between Yew trees to the left showed an obelisk in the centre of the opening, whereas, to please me more, it ought to be at the end most distant from the eye.

Through an opening towards the park a view is obtained of Monkenshaw Lodge, and the Roman Monument high above the Skell.

A little further on, turning to the right, a pillared pavilion dedicated to Fame is reached, and on all sides but one entered with difficulty. I cannot forbear protesting against visitors defacing the pillars by writing their names in pencil, and I hope such offending parties will some day be exposed.

I noticed as I walked along the Sabine Rose (*Rosa Sabini*) in flower, but whether indigenous or not I could not ascertain; and among wild plants I did not see any rarities, nor, excepting *Polystichum aculeatum*, any quantity of the Fern tribe. *Asplenium fontanum* was formerly very plentiful. The path is next among noble Oaks, and, though very closely planted, occasional glimpses of the valley create a longing after that noted Fountains Vale.

Arrived at Anne Boleyn's Seat, fatigue is forgotten as soon as the doors in front are thrown open. The prospect that then without warning bursts upon the eye of the spectator is beyond the powers of pen or pencil to convey. It must be seen to be appreciated, for it surpasses everything I ever before looked upon, and is lovely beyond comparison. In front are the ruins of Fountains Abbey, desolate but beautiful. The view is bounded on one side by limestone rocks and wood-covered hills, and on the other by a lofty wooded hill, and a brook gliding gently from the ruins through a green meadow to a lake that seems to wash the base of the peninsula on which the spectator stands.

Near to the ruins, on a neighbouring hill, are some Yew trees, under which the monks resided while the monastery was building. So says tradition. Their original number was seven, but their number is now reduced. Presuming the abbey to have been built in the twelfth century, these trees—taking into consideration the time that must elapse before they would be of sufficient size to afford shelter for the monks—cannot be less than a thousand years ago. After a stroll around and inside the abbey ruins, said originally to have covered twelve acres, I continued my route on to the Echo under the rocks, and re-entered the grounds by the rustic lodge.

I cannot quit this sylvan paradise—coeval with the works

of Kent and Brown, whose offers were often declined by W. Aislabie, Esq., who equally with his father had a good knowledge of landscape gardening—without expressing my regret at having so little time, and apologising for the desultory description given. Being my maiden description I ask for a little leniency from the sledge-hammer critics, though I am about to propose a few alterations.

I would suggest a copious thinning in some parts of the grounds, and planting in others. Some of the views require opening-out, and others are too wide from the point of vision. A judicious planting of the newer kinds of deciduous and evergreen trees and shrubs would add much to the beauty of the place, for the monotony of the vegetation, principally such as is indigenous to the locality, gives a sameness to most of the views. I regret they are not there already, for, judging from the few there are, the soil and climate appear uncommonly well suited to their growth; but I feel sure alteration may safely be left to the present owner of the grounds.

In journeying up the hill through the park I came to an obelisk, the view from which along an avenue mostly of Limes is very effective. Ripon Minster, at a distance of two miles from the entrance to the park, appears to stand at the end of the avenue, and beyond its towers a fine view of the open country is afforded. The avenue is about a mile in length, and somewhat broken in places; but still, whether looking towards the obelisk from the entrance gates or from it towards Ripon Minster, the effect is strikingly beautiful.

The trees in the park are some of them of large proportions. The Oaks are magnificent; one was 32 feet in circumference above the roots, and many were more than 30 feet round.—G. A.

(To be continued.)

CATERPILLAR-EATING BIRDS.

HAVING read with interest Mr. Robson's opinions on small birds, I venture to offer a few words on what I have noticed on the subject, as during the past season I have frequently watched the Black Cap (*Citurca atricapilla*), the blue Titmouse (*Parus ceruleus*), and the Chaffinch (*Fringilla cœlebs*); and I saw the two former feed their young ones chiefly with caterpillars, especially the Titmouse, the old birds taking two and even three at once. I have not seen Chaffinches feed their young with caterpillars, but I have seen them pick them off the trees by scores.

I will not attempt to speak of the harm all kinds of birds do; but I think there is not one that does not do some small amount of good at different seasons—for instance, the Blackbird and Song Thrush, inveterate enemies to nearly all kinds of fruit as they are; and I am inclined to say a word in their favour.

A nest with four young ones was taken from a tree, put in a cage and replaced for the old ones to feed, which they did, with what I cannot say; but I have found in the cage caterpillars that were dropped in feeding the young. What I have stated I have been eye-witness to, and I have no doubt that some of the craft that have had more experience and feel interested can give more light on the subject.—S. ROGERS.

HOW THEY LIVE AND LEARN IN THE NORTH.

MANCHESTER FIELD NATURALIST SOCIETY'S EXCURSION TO HARDCASTLE CRAGS.—On the 27th ult. about sixty members of the Manchester Field Naturalist Society visited Hardcastle Crags. Having given an invitation to the Tormorden Botanical Society, they were accompanied by about twenty-five of the members, and by an equal number from the Huddersfield Philosophical Society. The latter were mostly geologists and entomologists. The Manchester and Tormorden parties arrived at Hebden Bridge at half-past 1 p.m., and went to the White Horse Hotel, where many took lunch. They then started for "the Crags," two-thirds of the company consisting of ladies—among whom was Mrs. Hugh Stowell, who had the vasculum strapped on her shoulders in true British style; Canon Hanson (her brother) was also one of the party. While on their way up the valley, its

surpassing beauty, wood, hill, and stream combined—was the subject of universal remark; the ladies especially were lavish in their commendations, and long before the day's rambles were ended, had exhausted their vocabulary of terms in which to express admiration of the lovely and picturesque scenes in which they found themselves. Among the Ferns gathered were—*Polypodium phegopteris*, *Polypodium dryopteris*, or Beech and Oak Ferns; these were found in abundance all up the valley. Towards the top and near to High Greenwood, *Schistostegia pennata* (Shining Moss) was found in limited quantity. Lower down the valley *Hypnum ochraceum*, &c., and several fine forms of *Athyrium* and *Lastrea* were noted, and the fine evergreen fronds of *Polystichum lobatum* and *aculeatum* were conspicuous in very many places; a solitary plant of the *Asplenium trichomanes* was also seen. Many of the Manchester and Huddersfield parties had to return by the 7.30 train to take the 'busses, &c., from those towns to their respective homes. Afterwards those who were able to stay later took tea at the White Horse Hotel. Mr. Grindon, Secretary of the Manchester Field Naturalist Society, when tea was over, made a *résumé* of the day's employments and enjoyments, and the remainder of the party left by the later trains. Perhaps a company of so *élite* a character, in such numbers, never before visited the Harrogate Valley; the day was delightfully fine.—*Halifax Courier*.

MIMULUS CUPREUS AND AMARANTHUS MELANCHOLICUS.

I HAVE tried both of these this season. They were sown in strong heat in February. *Mimulus cupreus* grew very rapidly afterwards in a cold frame, always kept close, and covered with matting by night; it is now in flower, but about half of the plants are inferior in colour to the rest, one half being a rich orange scarlet, and the other a sort of washed-out orange. I have placed them in a ring round a bed of Heliotropes.

The *Amaranthus* grew readily, and promised well at first. I kept it longer in close heat. I hardened it off as gradually as I could, but the leaves turned yellow at the base, and then dropped-off in a truly melancholy way. Those plants only which have been kept in a close cold frame, and constantly supplied with liquid manure, are doing well.—S. L. J., *Cornwall*.

STRAWBERRIES IN FRANCE.

WORE to the man who ventures to express his opinion, if that opinion fall not in with the notions of exhibitors; and fortunate for him if, by a long course of no gentle application of abuse, his skin becomes rhinoceros-like, so that trifles do not worry him. The first place for experiencing the "pleasures of abuse" I give to the office of a judge, the second to the reporter of a flower show. If one happens to say that Mr. A's Grapes were superb, and Mr. B's magnificent, and Mr. C's excellent, even then the superlatives are measured out carefully; and if one be not as expressive as the other, but if Mr. D's are said to be wanting in flavour or colour, immediately all the "quills of the fretful porcupine" are protruded, and a great injury supposed to be done. Surely, the least thing one might expect is that credit would be given for fair intentions, even though one were set down as an ignoramus. And so M. Ferdinand Gloede attacks me for what I said about his Strawberries; and, if I understand his charges, they are these:—

1. That I had some sinister motive in representing his Strawberries as inferior.

2. That they were excellent, or they would not have obtained a first prize.

3. That the reason that they were not first-rate was because the Exhibition took place at a bad time for his plants.

1. As to this charge, I am at a loss to conceive what it means. I do not know anything of M. Gloede personally. I only know that he has written on the Strawberry so strongly that I was led, when I saw his name, to expect much. He is the correspondent of a gentleman whom I esteem very highly, and therefore I could have no motive in

misrepresenting what I saw. It could not be because he was a Frenchman, as I think your readers pretty well know by this time that I have ever desired to say what good I could of our neighbours, of whom, indeed, I am by descent one.

2. As to the second charge, I can only say that he had, if I recollect rightly, no competitor, and that there was not a bit of fruit at the Show that would have gained a fifth prize at our metropolitan exhibitions.

3. As to my possessing no knowledge of practical gardening, I do not exactly see what is meant. I certainly do not go out for a day's work, nor do I often take the spade in my hand; but I do claim to know a little about even Strawberries, and perhaps if I had said M. Gloede's were admirable, my practical gardening would not have been called in question. I did not pretend to know all about "practical gardening" in France, nor the climate of Les Sablons. I spoke of the Strawberries as I saw them; and that my judgment was tolerably correct is evident, I think, from M. Gloede's own showing, or else why endeavour to explain that the time was a bad one for him?

I have thus disposed of M. Gloede's critique, and would strongly urge him not to look for bad motives where none are intended, and to believe that if criticism is adverse it may at the same time be impartial.—D. Dea.

THE CULTIVATION OF ROSES IN POTS.

SECOND SEASON.

I PREFER potting in this way:—Having placed my compost on the potting-board, I procure a quantity of turves as they are brought in from the field, and very rough, pretty dry, well decomposed cowdung. The pots being drained, and on the potting-board, I tear off one or two large pieces of the turf, and put it into the bottom of the pot on the drainage, top downwards. In general this will be of sufficient height for the ball of the plant to rest upon; if not quite high enough, I put in a little of the mixed material to raise it to the required height; next, tear off pieces of turf, 6 or 7 inches long, and 2 or 3 inches wide, and as many thick; about four such pieces should be crammed in between the ball and the side of the pots perpendicularly. Between this, place large pieces of rough cowdung, nearly equivalent in bulk to the size of the loam, and fill up all crevices and cavities with the mixed compost, finishing off with the same, and making the whole quite firm. During the operations, care is required not to leave any cavities between the mould and pot, but to fill all up compactly. This is to be the treatment of the strong-growing varieties. The Teas, Chinas, &c., may be potted in a similar way, except leaving out a portion of the rough cowdung, and using more of the mixed material in its place.

This manner of potting may appear strange to some; but if such persons will give the after-treatment I shall now describe, the beauty of the plants in the following season will be to them equally novel. The great use of this rough potting during the following season of growth, will be apparent, allowing, as it will, water, whether soft, or liquid manure, to pass freely through, and the air to act upon the roots.

The plants ought now (September), to be properly trained—those intended for climbers, such as the Hybrid Chinas, Hybrid Bourbons, and strong-growing Noisettes, round neat stakes, 3 to 4 feet high. If these had been thinned during the previous summer, they will now require little or no pruning, but merely to have their branches tied neatly and regularly round, shortening the extreme points. Any very strong-growing Perpetual or other summer Roses, may be trained in a pyramidal form, by placing stakes round the side of the pots, and making them meet at from 2 to 2½ feet high, passing a hoop round them at about 1½ foot from the pot; the branches must be tied down to the rim of the pot, and round the stakes up to the summit, bearing in mind to keep the branches well down, as there will no difficulty in filling up the top the following spring. These, like the others, do not require much pruning; thinning-out where crowded, shortening where too long, and regulating the branches, will be enough. This applies also to the less robust Hybrid Perpetuals, Bourbons, Chinas, Teas, &c.; the plants

being all young, the wood thinned out and stopped when necessary, during the previous summer, they only require to be properly trained, with a little shortening. All the classes I am now speaking of, are best suited for bush Roses, and in training, the branches must be tied well down to the rim of the pot all round; any branches in the centre of the plant can be tied down to the lowest branches, but not in too close or crowded a manner. I am aware some first-rate growers recommend pruning many of these hard in, at this stage of growth; in this I can see no advantage, as the plants, under proper treatment, will be full of young wood, and to prune them hard would spoil the bloom. All that I find necessary is to thin out where over-crowded, to shorten where too long, and to properly regulate and tie out the branches.

The plants will now require to be placed in their winter habitation, and nothing is better than a cold pit facing the south, the lights being at a very acute angle, in order to catch every ray of light and sun. Let the plants be placed upon inverted pots, as close to the glass as possible, keeping the delicate varieties, as the Teas, Chinas, &c., at one end by themselves. Leave the lights off night and day during autumn, except in case of rains, from which they must be scrupulously protected. During the winter the lights must be off all day in settled weather, and tilted up by night to allow a circulation of air among the plants, shutting close only in case of very severe frosts and wet; slight frosts are not injurious. Through the winter they require little or no water. I have had them a month or two without a drop, and it should be given only when the mould is very dry; the great point of winter treatment being to protect the plants from rain, to give very little water, and to allow them abundance of air.

About the end of February, many of the Perpetuals, Bourbons, Chinas, Teas, &c., will commence growing, and the slight protection which they have will facilitate this. About this time they should receive a surfacing of rotten cowdung, from 1½ to 2 inches in depth, taking out a portion of the mould to make room for it, particularly by the rim of the pot. If it is desired to have a portion of the plants in bloom early, the end of February is an excellent time to remove them into a warm greenhouse—a span-roofed house is the best; and here the plants will progress rapidly, and come early into bloom. But I will leave this structure and return to their present quarters, and bloom them there. As the plants progress in growth they must be frequently looked over, tying the lower branches of all down to the rim of the pot, and the other branches of the dwarf Roses neatly and regularly down to them, but not leaving the centre open or bare. The pyramidal plants should be trained regularly from the rims round the sticks to the summit, and the climbers in a similar way; they should also be turned round in the pit once or twice a-week, that they may not get one-sided. Through the spring, while the plants are growing, particularly in March and April, air must be regulated with caution; the young shoots being extremely soft, the cold harsh winds of March would be very injurious to them, and from these they must be protected, giving air at that side of the pit from which the wind cannot beat upon the plants. By night they should be shut close to avoid spring frosts—these slight frosts being more injurious when the plants are so far advanced than 12° to 15° would be in the depth of winter. I have even found it necessary to well mat the pit where the Teas and Chinas were, in March, when severe frosts were expected, and the plants appeared liable to be frozen—a thing not unfrequent at that season. Alternations of the weather in spring are very injurious to delicate Roses; and, from the effect of a little frost at that season, I have

seen large branches and whole plants of Tea Roses die off; hence the great care necessary to protect them from frost and cold. At the same time, no opportunity should be lost of removing the lights from the whole collection every fine day, and for as long a time as possible, that the shoots may not be weak or drawn; they should be exposed to all the light, and to soft rains, which are very beneficial, protecting them from cold or heavy rains.

By the middle of April all danger from severe night frosts being past, they should have air all the night, by tilting up the lights at the back, and keeping the lights off as much as possible by day; following this up to the middle of May, when many will be coming into bloom. By the beginning of May the pots may be removed from under the plants, and they set on the bottom of the pit, provided it is not too far from the glass—not more than 9 inches. From the end of April to the end of May, and later, till the blooming of the last plants, the pits should be sprinkled every fine day, morning and evening, around the sides, on the ground, and over the foliage of the plants until the blooms begin to open, when it should be discontinued. It should be performed with a very fine rose-pot, or a syringe. The foliage, under this treatment, will be remarkably clean and healthy. In wet or cold weather this must not be performed, as mildew would be the inevitable consequence. After my plants had

been top-dressed in the spring, and when commencing growth, they received a watering of liquid manure. Such waterings are not necessary to be repeated before the end of three weeks; and after that once a fortnight will be often enough, until about the middle of May, sooner or later, according to the weather and the forwardness of the plants. About that time we may expect the buds to be swelling, and the liquid manure may be given once a-week, and continued through their blooming; when given the plants should have a good soaking, and at all intervening times from the commencement of their growth in early spring to the end of their blooming, soft water must be used.

All strong watery shoots as they make their appearance should have their extreme points pinched out when 6 inches long, and through the whole season of growth continual attention is necessary to tying, training, and taking off the suckers of worked plants as soon as they appear. From the com-

menement of their growth to the end of the blooming time, as soon as the least sign of green fly is visible, they must be fumigated. Caterpillars in the leaves and buds during growth should also be looked closely after. If the weather is fine about the middle of May, a little shade may be given for a few hours each day with thin gauze, as the buds by this time will be swelling. On the opening of the blossoms the plants should be moved into a cold north house, and kept rather close and shaded, where they will bloom finely; a cold pit facing the north will answer the same purpose, but in this situation they cannot be seen to advantage.

The Roses having bloomed, all dead flowers should be cut off, and the plants placed back in the pit from whence they were taken; here they may have plenty of air and light, and may remain until they have perfected their growth, during which time they may have liquid manure about once a fortnight. After completing their growth, let them be placed out-doors in an open airy situation, any straggling blooms or suckers that may be produced being cut off. The plants may remain out of doors until the end of September, when they will require fresh potting. This may be performed in the same way as the potting in the preceding season, except that the balls may be reduced a little more, and the plants being old will require a portion of the old wood to be

Rose Coupe d'Hébé.

cut out, and the young wood shortened, thinned, tied down and trained as before.—(J. SAUL, *Durham Down Nursery Bristol, in Gardeners' Magazine of Botany.*)

BLOOMSBURY WORKINGMEN'S FLOWER SHOW.

This took place on Wednesday last. There was a capacious tent between 60 and 70 feet long and about 40 feet broad, with the plants arranged on four lines of tables, one on each side and a double line down the middle. There were between 200 and 300 exhibitors, and between 400 and 500 plants entered for competition. Altogether there were more than 500 plants, as some were sent which could not compete.

The largest class was the one confined to the densest district in the parish, where the first Show was held, and which has kept the lead ever since. There were six classes in all—four for adults and two for the children at the schools. In every class were offered prizes for Fuchsias, Geraniums, and Annuals, three prizes for each in each class, the highest being 10s. for adults and 5s. for children.

At the last Show (1861) decidedly the best plants were shown by the servants. It is worth notice that the same servant gained all three first prizes at this Show, and, in the classes for Geraniums and Fuchsias, with the very same plants as those with which she gained prizes two years ago. This, at least, shows how well plants can be kept in an area for a long period.

In the plants which competed with hers were much more recent introductions into the parish. There is one thing connected with the Show which should not occur, and that is that numbers of people who have plants do not enter them for the prizes. If only half the plants in the parish were entered the Show would be twice as extensive.

One man sent some very good specimens of Dahlias grown in one of the worst parts of the parish, to which was given an extra prize. Mr. W. Sowerby was Judge; but, in spite of all his pains, of course there was a great deal of grumbling.

The *Times* made a mistake in saying that the miniature trees were shown by the school children. They were placed between their classes, but were lent by some ladies of the parish; and Miss Twining lent a small Palm which she had herself raised in a small pot.

The *Telegraph* made one very true remark—that those who seemed to know least of what was going on were the poor people themselves. There seems to be no means of rousing them.

Lord Shaftesbury gave away the prizes very judiciously, but in his speech made a mistake, which it must be supposed he had no means of knowing was a mistake, in lauding Mr. Bayley the Rector in connection with the Show, while he has not taken five minutes trouble about it; and Mr. Parkes and Mr. W. H. Bosanquet, who have had all the trouble, did not get one word of acknowledgment even from Mr. Bayley.

Between 2000 and 3000 people were present, and altogether it was a gay day for Bloomsbury. The inhabitants of the Square, whom there was such difficulty in inducing to give the use of the gardens, were delighted. Many prizes for annuals were not awarded.

WEIGHT OF FRENCH FRUIT.—At an exhibition last autumn at Chartres, in France, the following are the weights of some of the fruits—Pears and Apples. We have reduced the French weights to decimals of pounds, but we give the French weights also. It may, however, be useful to some of our readers to note that a kilogramme equals 2.2047 pounds avoirdupois; 1000 grammes equal 1 kilogramme. The weights are remarkable, but Belle Angevine, or Uvedale's St. Germain, has been produced of a much larger size in this country. The specimen exhibited at the St. James's Hall Show in November, 1858, weighing 5 lb. 15 ozs.

NOTES FROM AN INDIAN RAILWAY.

THE only fruits which I have tasted as yet are the native Gooseberry (*Physalis peruviana*) and Guavas. The former I like very much, the latter not at all, though Guava jelly is first-rate. During the rains is the time for the Indian fruits, so that I hope soon to write to you my ideas of Mangoes, &c.

You ask, "What do you live upon?" Moorgies (fowls), ducks, and guinea fowls—guinea fowls, ducks, and moorgies day after day, week after week; the only addition being a bit of mutton, certainly not oftener than once a fortnight, for though we have a mutton-club, we cannot get any sheep to supply the place of those we kill, so that we are very stingy about diminishing our stock. We live upon poultry for about a fortnight or three weeks, until we are heartily tired of it, and then some one ventures to suggest, "Isn't it time to have a bit of mutton?" Every one says that they think it would be a pleasant change, so next day our stock of sheep is diminished by one. After this piece of extravagance we return again to our moorgie diet, until in about another fortnight some one else is rash enough to make another very seductive remark about mutton being "very nice."

The Moorgies may be imagined as like a fattened magpie without a tail. These are called "chotah wallahs" (little fellows), and are used for curry. Though called "chotah," they never become larger, and they lay eggs no bigger than a pigeon's. The "bunra wallahs" (large fellows), are about the size of a small game hen; evidently of a different species to the others. Our game hens in England are most like them, and small bantams are somewhat like the "chotahs." They have neither crests on their heads nor feathers on their feet. When the engineers first came here they used to buy more than twenty for a rupee (2s.), but now we should think it very good to have sixteen for the same coin if they were all large.

You ask what chupatties are, of which so much was said during the Sepoy mutiny; and, curiously enough, on this very day on which I answer the question I have eaten a piece of bread—I may say the first piece during the last five months, and a very pleasant change it is too. We have a native who understands making it just come from Allahabad, so that I hope we shall continue to have that luxury for some time. I say "I hope" because these roti wallahs

(bread fellows) are very independent beings, and he may pack-up his things, and be off at a moment's notice.

But this does not tell what chupatties are. Fancy to yourself a piece of brown-bread dough rolled to about a quarter of an inch in thickness, and just warmed through so that the outside is dry—not crisp—and when you know, besides, that these things are about 8 inches in diameter, and perfectly flabby, you can then picture to yourself "chupatties." They are our substitute for bread in the jungle, and it is wonderful how soon one gets accustomed to them, though even a poor person in England would scarcely look at them, much less eat them. They are not unwholesome as you may conclude, for the extreme coarseness of the flour prevents them being so sodden as they would be if made of the finest flour, such as at home is used for bread.

The vegetables cultivated in the garden here are the same as in England, though, perhaps, not so fine. Cauliflower and Broccoli do not grow well, and, indeed, during this hot season, with the thermometer in the shade at 114°, the only kinds of vegetables we can obtain are Potatoes, a native Bean resembling Dwarf Kidney Beans, Vegetable Marrows, Cucumbers, and Melons.

They are all grown with a band (bank) round each bed, to retain the water about them with which they are irrigated every day from a well, whence two bullocks are incessantly raising water, which is conducted to the different parts of the garden by small channels on raised banks.

It is a very bad time of the year (May) to write about gardening, but I will give a sketch and fuller details hereafter.—A CIVIL ENGINEER.

ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, JULY 1ST.—The following new or rare plants, the names and awards of which were omitted in our last report, were exhibited in the Society's garden in the third and last great Exhibition, for the inspection of the Floral Sub-committee.

Messrs. Veitch & Son sent several new plants. Among them *Bomaria multiflora*, a showy climbing greenhouse perennial—first-class certificate; *Pteris serrulata cristata*, a useful and ornamental Fern, suited for a glass Fern case—first-class certificate; *Acrophorus affinis*, from Borneo, a useful Fern for baskets—second-class certificate; *Cattleya Aclandi-Loddigesii*, a hybrid Orchid raised by Messrs. Veitch, a very interesting plant, with rose-coloured sepals spotted with crimson—first-class certificate; *Dictyogramma japonica*, a Japanese Fern with fronds from 2 to 3 feet long—first-class certificate; *Ligustrum foliis variegatis*, a dwarf shrub with pale yellow variegated foliage—commended; *Asplenium consimile*, a Chilean Fern—commended.

Mr. Frost, gardener to Lady Grenville, Dropmore, sent a hybrid *Statice Frostii*, an ornamental plant with richly coloured flowers—second-class certificate.

Mr. Bull, Chelsea, exhibited *Ouvirandra fenestralis*, a rare aquatic plant with net-like foliage, and producing a forked spike of small white flowers—commended; *Arancaria Rulei*, seedlings of a new Caledonian Conifer—second-class certificate.

Messrs. Backhouse & Son, York, exhibited many specimens of their valuable collection of Ferns, among them *Trichomanes scandens*, a beautiful West-Indian Fern, remarkable for its drooping fronds—first-class certificate; *Hymenophyllum valvatum*, another drooping Fern—first-class certificate; *Trichomanes Kaulfussii*—second-class certificate; *Lindsaea stricta*, a pale green Fern resembling a Maiden-hair—commended; *Trichomanes alatum*—commended; *Trichomanes floribundum*—commended; *Adiantum Ghiesbreghtii*, a very handsome and ornamental Maiden-hair. Messrs. Backhouse also received a special certificate for their very valuable and rare collection of Ferns.

Rev. J. G. C. Fussell, the Chantry, Frome, sent a very superb specimen of *Gymnogramma chrysophylla*, a seedling form of the Golden Fern—commended; also *Llavea cordifolia*, a fine Fern, but rarely exhibited—special certificate.

Mr. Standish, Bagshot, sent several new plants, among them *Quercus* species with curiously-developed foliage—commended; *Asplenium elegantulum*, an elegant dwarf Fern, which appears hardy and suitable for the Fern case—

first-class certificate; *Selaginella involvens*, very beautiful, forming a distinct compact plant, and producing its bright green branches round a centre—second-class certificate; *Woodsia polystichoides Veitchii*, a dwarf Japanese Fern, very distinct from all other *Woodsias*—second-class certificate; *Funkia* species, a pretty herbaceous perennial, bearing drooping French-white flowers—second-class certificate; *Quercus* species, a fine broad-leaved Oak—second-class certificate.

Mr. Watson, gardener to C. Leach, Esq., Clapham, sent *Disa grandiflora superba*, a decided improvement upon the *Disa grandiflora* exhibited in 1861, the colour being much brighter and deeper; hence its additional title *superba*—second-class certificate.

Messrs. E. G. Henderson, Wellington Road, had a very distinctly-variegated *Primula sinensis*, with deep green foliage, strongly marked with yellowish stripes—commended.

Messrs. A. Henderson, Pine Apple Place, had *Gardenia florida variegata*, leaves boldly margined with pale yellow; a Japanese plant—commended.

FLORAL COMMITTEE, JULY 7TH.—A Meeting of this Committee was held in the right-hand upper terrace of the conservatory this day.

Mr. Keynes, Salisbury, sent two boxes containing thirty varieties of new Roses. A more magnificent collection was never exhibited; they were shown in threes, and for size and brilliancy of colour could not be surpassed. The Society's special certificate was awarded to the collection. The names of some of the most striking may interest the admirers of this queen of flowers. Among them we noticed—*Oliver Delhomme*, *Madame Boutin*, *Vulcan*, *Charles Lefebvre* (a first-rate flower), *Beauty of Waltham*, *Robert Fortune*, *Genevieve Bourdillon*, *François Lacharme* (first-rate flower), *John Hopper*, *Madame Clemence Joigneaux* (a very superior Rose), *Souvenir de Lady Eardley*, *Madame Julie Daran*, *Achévéque de Paris*, *Turenne*, *Souvenir de Comte Cavour*, *Maréchal Vaillant*, and *Monte Christo*.

Mr. Perry, Birmingham, sent a very excellent stand of twenty-four *Verbenas*, among which were some good seedlings which received the special certificate. A seedling, *Mauve Queen*, a delicate lavender-coloured flower, was commended. Should this variety bear the sun's scorching rays it will be a most useful bedding plant. Among other good seedlings were—*Purity*, deep bright rose, clear eye; *Rubens*, good form, deep crimson, white eye; *Motley*, deep rose; *Monarch*; and *Startler*.

In the collection of twenty-four varieties, we noticed—*Black Prince*, *Lord Elgin*, *Reine des Fleurs*, *L'Avenir de Ballent*, *Foxhunter*, *Colossus*, and *Lord Leigh*, the three brightest and largest-trussing scarlets. On this occasion *Foxhunter* was decidedly the best scarlet exhibited, and a variety which should be extensively cultivated.

While noticing the *Verbenas*, we must here mention that the Committee this day withdrew the first-class certificate granted 1862, to a *Verbena* named *Rugby Hero*, it proving to be on careful examination identical with *L'Avenir de Ballent*.

Messrs. Veitch sent *Selaginella involvens*, and *Selaginella involvens variegata*, both of which received first-class certificates. From the same nursery came three pots of *Lilium auratum*, one plant with the flower-stems bearing three flowers each.

Mr. Melville exhibited a seedling *Nemophila auriculæflora*, one of the dark chocolate varieties with a distinct white border—commended.

A seedling *Verbena*, *Princess of Wales*, a striped variety, was requested to be seen again, one imperfect truss only being sent. This was a promising flower.

FRUIT COMMITTEE, JULY 8TH.—A meeting of the Committee was held at the garden at Chiswick, Mr. Edmunds in the chair. Mr. Archibald Fowler, gardener to Lord Dalrymple, Castle Kennedy, N.B., sent fruit of a large white Fig, which appeared to be *Large White Genoa*. Mr. Cookson, Lenton Furs, Nottingham, sent a seedling Strawberry of the Sir Harry class, which was of good flavour and large size; but not sufficiently superior to those in cultivation to require any special notice.

The Committee then proceeded to examine the Vines in pots in the forcing-pits, and noted the following:—*Chasselas de Florence*, a form of *Royal Muscadine*, which sometimes

produces berries with a tinge of red on them, but in other respects it does not differ materially from the old variety. Chasselas Imperiale Précoce proved to be Prolific Sweetwater. A variety sent to the garden by Mr. Veitch, of Chelsea, and marked K, was found to be a remarkably fine early Grape, a fortnight earlier than the Royal Muscadine, and of a rich sugary flavour. It was recommended for further trial. Chasselas de Montauban was proved to be the same as Prolific Sweetwater; Minestra is the same as Frankenthal; Muscat de Clermont is Chasselas Violet; La Bruxelloise is Frankenthal; Madeleine Royale is the same as Chasselas Royal. These being all the varieties at present ripe, there the labours of the Committee ended. We would call the attention of our readers to this collection of Vines in pots, which is well worth seeing, and which reflects great credit on Mr. Eyles and his able aid, Mr. Barron.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PLY the fork frequently amongst the growing crops, and continue to manure. Trench-up every piece of ground as it becomes vacant, and plant it with Cauliflower, Broccoli, and Winter Greens. *Cabbages*, get ready a patch of ground for the sowings of this crop to stand the winter. The soil to be of a light sandy nature, and not too rich, as it encourages a luxuriant growth which is apt to make them more susceptible of injury from frost. In Coleworts make a sowing for the main spring crop. *Cypselums*, the plants to be kept watered during dry weather, and if mulched with a little litter they will not require it so often. Neglect of watering or mulching them now is frequently the cause of their not fruiting sufficiently early to ripen; they receive but little attention, and, consequently, they do not begin to grow till the autumn rains set in. *Celery*, the earliest-planted will now require to be gone over, and stripped of their small lower leaves and side shoots; the trenches to be then thoroughly soaked with water previous to the plants being earthed-up, which should take place as soon as the plants are quite dry. Prepare trenches for a late crop. *Carrots*, thin the late-sown crops, and loosen the earth between them where they have been sown in drills. *Dwarf Kidney Beans*, a last sowing to be made in a sheltered situation; the drills to be watered if the soil is very dry. *Endive*, plant-out finally the strongest from the early sowings, and sow also more for late crops; the small green-curbed is best. *Onions*, pull-up the crop of autumn-sowing, lay them in rows with the roots turned to the sun, and frequently turn them until the stalks are withered, when they will be fit for storing. As they are very liable to decay if bruised they should not be thrown about roughly, but handled carefully, and spread out thinly—not laid in heaps. *Lettuces*, sow more, and keep up a good succession of Radishes and Salads. *Spinach*, a good breadth sown now in rich soil will afford many successive pickings in the autumn, and tend materially to save the winter beds from being picked before they become strong. *Tomatoes*, they require frequent attention to cause them to ripen their fruit; the shoots to be thinned, and those left to be closely nailed to the wall; to be well watered, and then mulched.

When planting Celery, Endive, or any other culinary vegetable, it is unnecessary to deprive them of any portion of their leaves—indeed, the deprivation is injurious, which may be proved by trying both methods. Allow no waste of spare or bursted Cabbages, Greens, Cauliflower leaves and stumps, Bean or Pea-haulm, or, indeed, any other garden article, but give them to the pigs, if any are kept; and if not, they should at all times be tramped at once into the soil as manure, to assist in producing the crops which they are well calculated for, as it is, to some extent, returning to the soil what has been taken from it, together with what has been obtained from the atmosphere. This is a most beneficial and natural mode of applying assistance to succeeding crops. Continue to dredge the young Turnips, Cabbages, and other seedling plants with dry charred dust or wood ashes while damp early in the morning. Also continue to keep a watchful eye on the caterpillars that infest the Gooseberry, as they often make great havoc about the time the fruit is fully grown.

FLOWER GARDEN.

Attention will be well bestowed at this time upon bedded-out plants, deficiencies to be made up, decayed blossoms to be removed from Roses, and the young wood cleansed from insects. Continue to propagate Pinks, Pansies, and Picotees. Bud Roses, mow and roll lawns, and follow up assiduously the extirpation of weeds. Cover the blooms of Carnations and Picotees as they expand, placing cardboard collars beneath them. Layering may be commenced, beginning with the grass or shoots which are most forward. Look to Dahlias, thin-out where required, stake, tie, mulch, &c.

FRUIT GARDEN.

Especially Apples and Pears to have their leaders tied-in, the superfluous spurred. Attend also to choice Apples and Pears planted in the open quarters, but not trained. Remove superfluous shoots, and tie downwards the points of some of the strongest shoots to counteract their luxuriant growth. Attend to the stopping and nailing of wall trees in general. Remove all runners from Strawberries not required for making fresh plantations.

GREENHOUSE AND CONSERVATORY.

Attend to the greenhouse plants now placed out of doors. See that worms do not effect an entry into the pots, and attend to the routine of tying, stopping, and other details. The season has now arrived when those hardwooded specimens which require a second shift this season must have it without delay, at least before the end of the month, so that the pots become well stocked with roots before the autumn. Be guided in shifting by the strength of the plants. If growing robustly a liberal shift to be given; but if not, a smaller one must suffice. All plants which have done blooming to be cut-in, preparatory to starting for new growth; the decayed flowers and seed-pods to be removed before they exhaust the energies of the plants by perfecting their seeds. Many of the stove plants in some places will be now occupying these houses while the regular tenants are in the open air; but as many greenhouse plants, such as *Eriostemon*s, *Coronias* of various kinds, and other New Holland plants require the assistance of a little heat to insure their making a good growth, they may be kept in the house with the stove plants, regulating the temperature so as to be agreeable to all the inmates. Keep a moist atmosphere, especially towards the evening, and shut up for an hour or two about the time the sun leaves the house.

STOVE.

As many of the principal plants of this house will now be in the conservatory or greenhouse, advantage to be taken of their absence to encourage the others for winter-blooming, especially such as *Justicias*, *Begonias*, *Aphelandras*, *Eranthemums*, *Clerodendrons*, *Rondeletia speciosa*, *Lunelia gratissima*, *Torenia asiatica*, *Pentas carnea*, &c. A batch of *Achimenes picta* and *Gesnera zebrina* to be started for the same purpose. Maintain a moist growing atmosphere with plenty of air, and guard against insects. Where a house or pit cannot be devoted to the Azaleas this will be a suitable situation for them, but they are better by themselves.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

MUCH as last week. Made the most of the little water we could command to keep Peas, Beans, Lettuces, Turnips, growing and crisp, and shading a little to break the force of the sun's rays. Watered Cauliflowers, except what was nearly fit for use. Earthed-up the forwardest succession, leaving a hollow along the middle for future waterings, and earthed-up chiefly to keep the water we gave round the roots. Instead of taking the remains of the Cauliflowers to the rubbish-heap as usual, will most likely strip off all the leaves, and lay them along the sides of the advancing crops, to shade the ground and keep the moisture in.

Never have we witnessed such glorious weather for securing the haycrops in first-rate condition; and notwithstanding the drought, Turnips that are pretty forward in the fields are looking well. All cereals that we have noticed, with the exception perhaps of a little patchy Barley, are from their beautiful appearance enough to fill every heart with gratitude. It is only in gardens, where the water-

supply is a very serious consideration, that such glorious days and bright suns bring with them any feeling of anxiety and alarm. This great water question has for a long time been like a coil of ropes round our legs, impeding freedom of action. If a bit of envy should ever enter and find a short resting-place in our mind, it would be from seeing a garden where water in abundance was ever present, and where, by the mere placing a pipe on a tap, quarters of Strawberries and vegetables might be flooded at will. There can hardly be a comparison made between such a place and another in which water must be dribbled out as if it were wine. The practical deduction to draw would be the importance of securing such water-supply for the site of a garden, and the imprudence of fixing on the top of a hill for a garden, and especially if there was much done in the way of bedding plants, the water to be depended on being merely that which can be caught from the atmosphere.

We are rather pleased than otherwise that the hint the other week about landlords building cottages and leaving the tenants to scour the ditches and dirty pools by the highway for water has so far told. Entering into particulars is out of the question. Kindly intentioned improvement—not bitter acrimonious criticism or exposure—will ever be our motto and practice in such matters. We are well aware of what one correspondent tells us, “that many landlords would be horrified at such a state of things, which exists solely from their ignorance of the matter, and from no want of kindly sympathy.” Then would it not be good policy to try in a quiet way to dispel that ignorance? Philosophers may debate, and never settle, how far, if at all, human character is moulded by mere circumstances. Simple observation tells us that there are men of such strength of determination as to rise superior to all circumstances of position, however seemingly unfavourable. With the mass of us common folks circumstances exert a most powerful influence. Look at that little girl, who, with the instinctive love of the beautiful so largely inherited by woman, is as much or more pleased with her pretty new frock than the belle of the ball-room is with her satin and pearls. Would she be so likely to roll in the dust and the mud (though children may do much worse), as if clothed with a ragged garment, so dirty that it would require a microscope to speak of its colours? We could instance the wonderful transformations, even in outside appearances, effected by moving a family from a tumble-down rickety homestead, and settling them in a nice cottage, on the conditions that cottage and garden were to be kept clean, and the latter well cultivated. Even in such a cottage, however, a woman’s attempts at cleanliness and honest respectability of position, must be greatly neutralised if she must hunt the ditches to get even a little of muddy water. If a few more landlords would inquire into such matters for themselves, we would be delighted.

SURFACE-STIRRING.

The general reader will, we trust, excuse the above digression as to pure water for cottages. The want of plenty of water in the garden has caused us to resort to many makeshifts. Surface-stirring is one of the most generally applicable. From several notes received there seem to be much doubt and darkness still existing on the subject. One lady tells us that her plants are dying, that the ground is very hard on the surface and is cracking in many places, and that she imagines that if she slightly forked over her ground she would be still worse off, as the heated air would penetrate and dry up her soil more and more, until the roots could find no moisture to nourish them. The dry hard-baked surface of many a border and bed is sufficient evidence that such an idea is very general. It is, however, based on a thorough fallacy. Here, however, let us note that an excess of luxuriant growth and an excess of fruitfulness are two very distinct things. To secure great fruitfulness at the expense of diminished growth the soil can scarcely be too firm, either at the surface or anywhere else. To secure rapid growth the soil should be more loose, and the surface open enough to receive the air and its oxygen. Thus, to secure a dwarf standard or pyramidal Apple tree, we must resort to means somewhat different from those we should adopt for securing a very large head of Cauliflower. In the first case we should have what firmness we could, with as much mulching or more moving of the surface as would

prevent cracking, and in the second we would have deeper than surface-stirrings of the soil in order that air should get to the roots, that the roots themselves might be multiplied, and thus the organs increased for sucking up the rich waterings presented to them. We have often seen a piece of ground in Cabbages that had become case-hardened in April or earlier wonderfully improved in its appearance in twenty-four hours merely from deep surface-stirring, say 3 or 4 or more inches deep—a very different thing as respects roots and air from mere surface-scratching with a Dutch hoe, &c., though that, too, has its uses and advantages. By such means the air is admitted, to effect mechanical and chemical combinations with the materials in the soil; but the great effect upon the Cabbages is not produced so much by letting heat in and moisture out as our correspondent, by her reasoning, might suppose, as by quite contrary means—namely, the keeping the moisture in and the heat out.

On this principle, when we wish to get a mass of soil as much heated as possible by the sun’s rays, we would have the soil firm and the exposed surface smooth and level rather than rough. Hence, when we have wished to obtain very early Cauliflower under hand-glasses, we have kept the surface of the soil rather smooth and firm in early spring, that the great stimulus of heat should get down to the roots, and then as the leaves began to shade the ground and we could receive little help from direct absorption and conduction of sun heat, we have then stirred the soil for the purposes already stated. All this we should do on the simple principle that, as a general rule, bodies absorb, conduct, and radiate heat in proportion to their density. Thus, if we place a two-foot rod of seasoned wood in the fire, we may hold the end of the rod without feeling any inconvenience until the flame of the burning wood comes too near to us; but if we place a similar bar of iron in the fire, the end which we grasp would soon be too hot for us. In such an experiment the wood should be old and seasoned. We recollect long ago, when burning a piece of green wet Ash and holding it by the end, it got so hot that we thought we had discovered some unknown heat-conducting power in the Ash; but we had done nothing of the kind—the moisture in the wood was heated by the fire, and was thus forced through the pores and vessels of the wood, just as steam or hot water rises from a boiler.

We come, then, to two conclusions—first, that firm soil is by absorption and conduction sooner and more highly heated by the sun, and just so much sooner cooled by radiation of heat when the atmosphere is colder than the ground, than a loose open soil would be; and, therefore, surface-stirring arrests extra heat from the sun during the day, and lessens the loss of heat by radiation at night; and secondly, as the loss of moisture by evaporation is in proportion to the heat applied, then the looser the surface the less the amount of moisture raised by evaporation. Those who still doubt as to the first, may satisfy themselves by burying two thermometers that indicate alike—say 1½ inch from the surface—the one in loose soil and the other in very firm soil, the soil in both cases being of the same consistence as to dryness, and examining both at 5 p.m. after a sunny day. We will be surprised if that under the firm soil do not show the higher temperature. After a dull day and a clear night we should expect it to stand the lower of the two in the early morning.

We satisfied ourselves as to the second in a very simple manner. We took two good-sized bell-glasses with rounded conical, not flat tops, because we wished the vapour raised during the day not to drop from the top when condensed, but to run down the sides. The bottom of each glass was then fitted into a lead gutter, formed of the material often used for the small squares of cottage windows, but which we trust will be soon superseded for that purpose by cheap glass. These two glasses with their troughs were set, one on firm ground and the other on moved ground, but as much alike as possible in other circumstances, and both full in the sun, care being taken by earth and putty outside that neither air nor vapour should enter the glasses from without, so that whatever moisture was found within in a morning must have been entirely owing to the heat of the sun raising it as vapour from the ground enclosed. The results were very varied; but when the glasses were examined early before the next morning’s sun had time to vaporise

the condensed moisture trickling down the sides, the general fact arrived at was, that the trough in which the glass stood over the solid ground had most water in it. The same results we believe would take place in every garden and field according to their relative circumstances. True, on stirring soil with fork or share, the heat of the air would enter, and in proportion to the dryness of the air, would the soil be deprived of superabundant moisture, and other chemical and mechanical advantages would follow; but the heat admitted would almost entirely be the heat of the air near the surface of the ground, and not that accumulated heat from the sun's rays striking repeatedly on the same solid spot. In the first case, too, the conduction of heat downwards is arrested by the open surface; in the second it is assisted. The surface-stirring acts, therefore, in both cases very much like the shade of a thick mat spread over the ground. Putting a cold hand successively on iron, stone, firm smooth earth, and loose earth exposed to the sun's action, would almost decide the matter by the mere sense of touch.

The strongest argument a friend suggested against such conclusions was gained from the well-known fact, that tender fruit trees against houses and cottages often fared better than in gentlemen's gardens, even though they scarcely ever had any waterings, and the ground above the roots was either paved or pitched. How did the roots get moisture at all if the heat of the soil and the evaporation from the soil were so much in proportion to the firmness of the surface? We think the case on the other hand is quite in our favour. The earth being close to the paved surface got more heated in spring than a common garden border would do, and thus roots would be stimulated in unison with branches. So little is this the case in general with trees against walls at the back of cropped borders, that it is quite common to shade the wall in early spring, or to leave the twigs dangling from the wall, and thus keep them colder than they otherwise would be until the earth would get a little heated. A vast deal has been written on concreting the bottom of borders; but we believe much might also be done by concreting the surface as soon as the trees were established. Then as to the moisture question, there need be little fear of that if the roots are not wholly isolated from the surrounding earth. We cannot say how far a good healthy plant will draw moisture for itself in such circumstances, but the greater the evaporation, the greater the quantity attracted to supply it. We once had a Vine-border that could not receive from above a drop of water for five years, and yet on uncovering it, it was found to be just nicely and healthily moist. The leaves were less, and the fruit more abundant every year; and on taking up the pavement over the roots of fruit trees trained against a cottage, we have generally found the soil nicely moist though not wet. This is, however, another side of the question—fruitfulness *v.* luxuriance. The principle fairly understood, we can easily vary it, just as we would bring such knowledge to bear very differently on two young Cabbage plants, one of which it was desired to bloom as soon as possible, and the other to become in the shortest time a great thumping head to fill the tray at the hall table.

ORNAMENTAL GARDENING.

We skip other departments to continue the practical illustration of the same principle. In addition to much of what was stated last week we knived part of the lawn where there were some Daisies, in preference to mowing, as it is not desirable in such warm weather to make the grass too short. The chief work, however, has been regulating beds and borders, hoeing or surface-stirring, watering what we could, and then almost immediately covering with a slight layer of leaf mould and old Mushroom-dung. Generally we used to pass all such material through a one-inch sieve, and then add to it a little soot and lime before strewing it over the bed, as these latter ingredients tend to keep the beautiful birds scratching it about over the lawn, and this they can hardly attempt when the beds are too thick for their bills and shoulders. This year, being scarce, we have been obliged to use leaves of this season rather too rough for the back rows, and our old mixture for the front rows and all the smaller beds. Now, though we consider this covering from half an inch to an

inch or more as a capital thing when rightly used, the right use depends much on the time and the season. Scarcity of water has made us resort to it sooner than we otherwise would have done, when a still warmer soil would have done no harm, whilst the great heat would have prompted us to thus mulch some things sooner than we did. We shall now for some time be pretty independent of the water-pail as respects those beds thus managed. Rougher things, such as Dahlias, have had a dressing of short mowings, and without any watering they are standing well.

As examples are best remembered we will single out two classes of favourite bedding plants, and show how the same principle would apply to them somewhat differently. First, there are the Scarlet Geraniums. We believe the summer can scarcely be too bright and warm to insure their doing first-rate out of doors. In a dull summer and wet autumn they are more prolific of leaves than flowers. So much is this the case, that in such circumstances, and but for the expense, planting in pots, would be best—in fact, treating them like the tree with its roots under pavement. So well convinced are we that these plants like a warm soil, that we would stir the surface but little, and would not mulch at all but for the dread of the plants being dried up. As our ground is poor, half an inch or so of the compost just helps to prolong enough of vigour for flowering, and keeps the moisture in. Then, secondly, there are the Calceolarias, which are now so beautiful, and which, in our opinion, require quite different treatment. These plants will often do well in a dull cold season, when Scarlet Geraniums only pretend to mass with bloom; but we have never known the brightest and longest-continued sunny weather have any other effect on them except to make them brighter, provided the roots are kept cool and moist. Neglect these provisos, and we will not say much as to the results we would anticipate in such circumstances; hence in their case we early and frequently stir with hoe and fork the surface soil, and this is likely all we would do if we could water them often with cold water; but as we cannot do so, and as by midsummer the soil is generally warm enough for them, we give them a mulching of the riddled Mushroom-dung and leaf mould, and would give them more than 2 inches instead of 1 if we could afford it; and in hot dry weather such as this we make a boy just move the surface of this covering, which thus breaks the line of conduction and of evaporation, and so helps to keep heat and moisture in, on the same principle that we defend ourselves from too bright a fire when seated near it by placing a fire-screen between it and our bodies.

We are very short of this mulching after clearing out all our Mushroom-beds—for the first piece in the open shed is now too much covered with Mushrooms. However, as there were only a couple of inches or so of good stuff on the surface, if the bed continues long thus prolific we shall be agreeably disappointed, and have taken measures for succession accordingly.

Our chief fresh work in the fruit garden has been layering more than a thousand Strawberry plants in small pots, as mentioned a fortnight ago.—R. F.

TO CORRESPONDENTS.

* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

BURNING SURFACE SOIL (G. H. W.).—In No. 96 of this Journal are full directions for paring and burning. Buy "Manures for the Many," just published at our office; you can have it free by post for four postage stamps, and it contains the same directions.

DESTROYING WOODLICE (*W. T. Suffolk*).—Wrap a little hay loosely round a boiled potato, and place it at the bottom of a flower-pot. Lay the pot so bared on its side near your ferns, and every morning shake the woodlice out of the hay and off the potato into boiling water. Rewrap the potato to the hay, &c., and continue to do so until the pest is extirpated. A much nicer plan for ladies and gentlemen is to cut a raw potato in two equal parts: scooping out the cut part a little with the knife, and then placing the half-potatoes, with the cut or hollow side downwards by the side of the eaten ferns on the soil or sandstone. Every morning treat the woodlice to a boiling bath: you will find them secreted under the potato and adhering to it in the hollow. This is so clean a plan that any amateur gardener can adopt it. The potatoes will last well for a twelvemonth, but not in frosty weather. As your ferns are so much eaten examine the plants after dark with a lantern, and you will, not improbably, find some slugs at work; if so, pick them off into a flower-pot, and sprinkle some salt over them; or if you have any ducks they will thank you for the present unsalted. A few fresh cabbage leaves will enable you to catch hundreds of slugs if the leaves are placed near their haunts, and are examined every morning.

LAPSTONE KIDNEY POTATO (*A Nine-years Subscriber*).—We think it ought to be entered in the class for late Kidney Potatoes.

BEST EIGHTEEN PENTSTEMONS (*S. S. S.*).—Admiral Lincoln, Brilliant, Charles Watson, Coccinea Magnifica, Cyrus, Flora, Dr. Hogg, Illuminator, Juno, Léon Kera, Poirée Prince, Scarlet Gem, Sultan, John Salter, Tynningham, Rose of England, Carl Apphus, Albicans.

BEST EIGHTEEN FLOXES (*Ibid*).—Boule de Nègre, Comte Vigier, Eblouis-sant, Flore, Hôlé, La Candeur, Le Vêve, Liervall, Madame Liervall, Madame Van Houtte, Mlle. Aouds Aubert, Ne Plus Ultra, Madame Standish, Souvenir de Mons. Fries Morel, Sarpassé Madame Readatier, Triomphe de Twickel, Vénus, and Mr. Kollisson.

SIX NEW AND GOOD GLOXINIAS (*Ibid*).—Bird of Paradise, Cornelia variegata, Lady Diana Beauclerc, Lady Feodora Wellesley, Levantine, and Most Beautiful.

HARDY HERBACEOUS PLANTS (*C. H. S.*).—You can obtain plants of the less common from any of the florists who advertise in our Journal. Write to them for a catalogue and you can select for yourself.

SPECIMENS OF PLANTS (*A. B. C.*).—No letter accompanied them, so they were thrown away.

FERNS IN WARDIAN CASE (*T. E., Dublin*).—Too much light and too little ventilation will make the fronds turn brown. Our fern case never has the sun shining upon it, and has the sides partly open all the day and night.

SEEDLING PANSIES (*Dr. C. Stuart*).—Of those sent Midnight seems to be the best (we say seems, for they were so dry it was hardly possible to accurately judge them). It is very dark; and if it have a good habit, as you state, for bedding, it will make a valuable addition to those we already possess. In sending flowers avoid wadding. A tin box with damp blotting-paper (or one on Mr. Mellan's plan), should be used.

AMARYLLIS LONGIFLORA ROSEA FALLING (*Pond-dhu*).—The warm heat of a plant-stove or cucumber-frame ought to have brought out the blossoms of your Amaryllis, as they generally expand well enough when they are formed. The offset you mention will not bloom this season probably, but by being well ripened will perhaps do so another year. Be sure and let it have a good long rest, rather cool than otherwise; and though it ought to be kept dry, a too great extreme in this is not to be recommended.

AUBRETTIA PURPUREA EDGING (*J. B.*).—Seedling plants of this may be planted any time during the summer, or slips of older plants may be put in during showery weather; but it is better to put them into some shady place to strike and then plant them out. Old plants, however, yield rooted layers or offsets, which do very well. As an edging, it looks best when it overhangs and grows amongst stones; but it may be grown near a grass verge, in which case about 10 inches will not be too far off, if you allow it to attain a good size afterwards.

PEARS DECAYING ON THE TREE (*K. W.*).—It is no unusual thing for Pears that have been attacked by an insect while in the bloom to swell to a certain size and then fall off, but we never knew the whole crop to be so affected. It would be advisable in your case to examine the diseased fruit, and see if there be any insect in them to account for the premature decay. Many Apples, and Pears too, drop shortly before arriving at maturity in consequence of an insect which has either burrowed into their side, or its larva being deposited while it was in bloom, and it advances with the fruit. There is no preventive to this, but there are generally sufficient left unburnt for a crop. Write us again if yours all drop at a certain size. Some kinds we know are addicted to this in unfavourable seasons. It seems as if the conditions necessary to bring the fruit to perfection were not in existence at the time, and the tree refused its support to them and decay ensued. We have seen a tree of Williams' Bon Chrétien so affected, but it is not at all a common occurrence; such a general failure often is caused by a parasitic fungus.

HUMEA ELBOANS NAKED AT BOTTOM (*Bovody*).—The cold winds in May were one of the causes of this plant losing so much of its foliage, as we have plants 10 feet high with the same fault; but as they are flowering well at top we must not object to their naked bottom. We have, however, surrounded the base of our plants with tall-growing things, as Chrysanthemum regium plenum, tall Lobelias, African Marigolds, and the like; and another season we may very likely plant a Maudslayi, along with the Humea. Do not by any means cut it down.

HYBRID PERPETUAL ROSES ON THEIR OWN ROOTS (*E. G. E.*).—In favourable situations most of the ordinary kinds will do pretty well in a bed, but some that we have tried did not succeed. Of those that do best we may name Caroline de Sansal, Baronne Prevost, Baronne Halez, Géant des Batailles, Jules Margottin, Souvenir de la Reine d'Angleterre, Madame Rivers, Paul Ricant, Général Jacqueminot, Madame Hardy, and William Jesse. Others might be added, but we prefer limiting our remarks to such as we have found do best. We are, however, promised an article on the subject from one of our contributors.

GREEN SLIME IN AQUARIUM (*E. D. S.*).—The only mode of prevention is by changing the water frequently. We have a syphon, and change the water of one in a drawing-room daily. The "whitish powder" on your Grapes is the mildew (*Oidium Tuckeri*), and will destroy them if you do not dust them and the leaves thoroughly with flowers of sulphur.

HEATING A SMALL CONSERVATORY (*A. L. B.*).—No stove without a pipe or chimney ought to be admitted among plants—it slowly destroys them. We had such a small conservatory once, and we heated it by a gas stove, but with a pipe to carry off the fumes resulting from the combustion of the gas.

ROSES FOR FORCING (*Idem*).—The following are good for the purpose. *Hybrid Perpetuals*.—Baronne Prevost, Dr. Marx, Géant des Batailles, Jacques Laitte, Reine des Fleurs, and William Jesse. *Tea-scented*.—Abriote, Comte de Paris, Devonensis, Niphetos, Safrano, and Vicomtesse de Cazes.

SEEDLING STRAWBERRY (*J. Cookson, Lenton Furs, Nottingham*).—Your seedling Princess Alexandra is a large dark-coloured Strawberry of the character of Sir Harry, and does not supersede that variety in any of its points. We therefore think, notwithstanding its great merit, that it is not desirable to increase the varieties already in cultivation by adding this one to them.

VARIOUS (*F. B. F.*).—A zinc case kept filled with hot water would hasten the germination of seeds. Its top should be covered with sand, and the seed-pans plunged in it. We could not say whether the flower you name is a Carnation or Picotee, not having either an inspection or description of it. Guano and superphosphate of lime would enable you to grow kitchen-garden crops without other manure.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ISLINGTON AGRICULTURAL HALL POULTRY SHOW.

HAVING seen a communication from the authorities of the Crystal Palace stating they had discontinued holding poultry shows and offering to sell to the Agricultural Hall Company the pens used at their Shows, I was asked my opinion of holding a poultry show in connection with a flower, fruit and vegetable show to take place in the last week in August. Knowing the decision came to, or as every one would suppose, had been come to, after offering to sell the pens used at the Show at the Palace, I advised a poultry, pigeon and rabbit show to be held in connection with the flower show at the Agricultural Hall, Islington, and this was sanctioned by the Finance Committee and liberty given to offer a very liberal prize list. We then go to the Crystal Palace on the 28th June and are asked by the head official to buy the pens, knowing the Agricultural Hall Company had in contemplation holding poultry shows.

This I beg of you to lay before the poultry exhibitors, as I am highly compromised by the recent announcements of the Crystal Palace Company. It was neither the intention nor spirit of the Agricultural Hall Company to commence an opposition to the Crystal Palace Show; but they were induced to adopt a poultry show through my representations, and my object was for the benefit of poultry, pigeon and rabbit breeders.

After having been informed by letter from the Crystal Palace Company, and by word of mouth from its official, who I concluded was authorised to sell the pens, now they state that a rumour has prevailed that the Show was to be discontinued, but that no such decision was ever arrived at.

After offering to sell their poultry pens it seemed as if poultry-breeders would be left without a summer show for chickens; and as the Agricultural Hall Company kindly took the Show up, it will be to the interest of all breeders to support their proposed poultry Show. I now leave it in the hands of exhibitors to say whether I was justified in doing as I have done.—JOHN DOUGLAS.

WHEN EGGS SAT UPON ARE UNHURT BY BEING CHILLED.

I NOTICED in your Journal the inquiry relative to eggs being sat upon and then chilled. The following is my experience of two cases similar to that of the inquirer.

Some years since I placed fourteen eggs (Golden-spangled Hamburgs) under a Game hen about ten o'clock on the Saturday night. She seemed to sit close, but the following morning I found the hen off at six o'clock. I gave her food and water, but could not induce her to notice the nest again for some hours. I removed the eggs and gave them to her at 8 o'clock on the following Monday morning, not thinking to have a chicken; yet at the expiration of three weeks she brought me fourteen beautiful birds. This year I placed fourteen eggs of Golden-spangled Hamburg under a hen on Thursday night, April 23rd, about nine o'clock. She sat close till eight o'clock on the following morning,

she then came from the nest. I gave her water and food and she returned to the nest, remaining on until ten o'clock. She then deserted the eggs until four o'clock in the afternoon, when she came to the nest and laid, and then sat with a good will. On the following Monday morning about eight o'clock I placed under her the same eggs she sat on before. This time I was full of confidence, and should be

again, for she hatched thirteen beautiful chickens, and now they are doing well.

I should not object to sit a hen on eggs that had not been sat upon more than twenty-four hours, for I am of opinion that vitality does not commence until after that time. I have a friend who has had a similar case this season, and all the eggs yielded chickens.—T. MAY.

HEN-AND-CHICKENS COOP.

I HAVE had coops for chickens made of many different kinds, but all cumbersome to move and stow away in the winter, and occupying much room. Lately, at a neighbour's I saw some which I think excellent, and am induced to send the particulars.

The coop is made without a bottom, to be placed in an orchard, &c., as may be convenient, and two (one inverted) can be stowed away in a loft compactly. Next, the enclosure is formed of two boards placed edgewise, with a shorter one at the end, fastened at the corner, and attached to the coop by small wire hooks, hooking into wire staples.

Then there are three deal frames filled in with galvanised wire netting, two lying horizontally on the boards forming the enclosure and one standing upright against the front of the coop, and just retained there by similar hooks, &c., to those spoken of before. Pretty enough did the chickens look running about beneath the wire. The hen was in the coop, and the sliding-bar let down.

Now, the advantages I conceive to be these. The chickens are restrained from wandering into the high and wet grass, and their food is protected from the small birds and themselves from cats, and the whole is comparatively inexpensive. Because, walking over the kitchen garden, I found similar boards (forming the enclosure) and similar wire-filled frames in use by the gardener to protect seed-beds. I think the boards might also be found useful in keeping together and tidy the covering put over late Sea-kale; and the frames, elevated at the four corners by means of inverted flower-pots, might be found useful for drying onions before storing, and, covered with paper, for drying seeds, &c., either on the ground or on the front stage of the greenhouse—useful, because air would be admitted beneath the roots, seeds, or fruit.—S. C. W., *Bromley, Kent*.

EGGS SAT UPON AND THEN CHILLED.—In reply to "EVESHAM," I am quite convinced that the hen sitting upon the eggs for only seven hours could

not possibly be the cause of their being addled. I have tried similar experiments, and have taken the eggs from the hen after sitting close for twenty-four hours, and at the end of a week or eight days I have again placed them under a hen, and the result was eleven chickens out of fifteen eggs. I tried this three successive times with Dorkings, Game and Cochins, the result being the same.—WESTMORELAND.

LOSS OF QUEENS—PROCEEDINGS OF BEES PRIOR TO SWARMING.

EVENTS proved the correctness of your verdict in page 464 of the last volume, that the queen ejected from my storified-hive on the 25th of May was the mother of the hive. She must, however, have been assassinated by her subjects, as twelve days elapsed before the commencement of piping, and it was not until the thirteenth or fourteenth day after her expulsion that the bees attempted to swarm. It seems that even a fertile queen is exposed to some risk when hives are transposed, as the following will prove:—On the 20th of May I made a small swarm by placing two frames of brood (one of them containing a nearly mature royal cell), and two frames of empty comb into a four-frame nucleus-box; and on the 16th of June, finding that the young queen had laid a considerable quantity of eggs, and that the combs were well filled with brood, I determined to shift the four frames with their queen into a full-sized ten-frame hive, and transpose them with my first swarm of May 9, which was

becoming so crowded that I apprehended a maiden swarm would shortly issue forth if not prevented.

The operation was quite successful as far as the workers were concerned, very little fighting taking place, but on the following morning I found the young queen dead in front of the hive. Happening to have a very fine Italian queen in my unicombed-hive, I caught her and carefully introduced her to the queenless hive, as recommended by "B. & W." I placed her with only two of her subjects under a small bell-glass, and putting them over the aperture in the crown-board, with a slip of perforated zinc to regulate the admission of bees from below, slowly and cautiously permitted the bees to ascend. Finding them all well disposed, in less than two hours I withdrew the slide entirely, and the queen with a considerable number of bees which had been allowed to ascend, speedily disappeared between the frames. I examined the interior of the hive a few hours afterwards, and

was pleased to find the queen at liberty receiving the adoration of her new subjects.

The bees in the unicomb-hive made four royal cells, and I had for the first time an opportunity of witnessing the conduct of the senior princess and also that of the workers previous to the issue of a second swarm. The queen at liberty constantly attempted to reach the royal cells containing the imprisoned queens, and frequently got quite to one of the cells, but the workers would then seize her by the leg and chase her until she was several inches from the forbidden territory; they then appeared to rather fawn upon and caress her. A swarm issued forth on the eighteenth day from the abstraction of the old queen. I also observed that the aperture in the royal cells containing the imprisoned queens was not small, as I should have inferred from Dr. Bevan, but the end of the cell was entirely nibbled away long before the queen gained her liberty.

After the departure of the swarm the hive appeared almost depopulated, but a small knot of bees still kept vigilant watch over the imprisoned queens, and I did not see the elected one at liberty until the morning of the 7th inst., twenty days after the loss of the old one. The first young queen was very dark and not at all visibly different from an English queen, but I am glad to see that the one now regnant is very well marked and a most decided Italian, and may turn out a first-rate queen.—J. E. B.

[The instance above related tallies with our own experience, that strange bees cannot be introduced into any stock, either by transposing or by any other means, without considerable danger to the queen regnant.]

VARIATIONS IN THE COLOUR OF QUEENS AND DRONES.

I MUST dissent from the conclusion arrived at in the editorial reply to "A HAMPSHIRE BEE-KEEPER," in page 20, since it appears to me by no means correct, but, on the contrary, highly improbable, that the so-called yellow-banded queen possesses the slightest trace of Ligurian blood. Had the old queen met a Ligurian drone as suggested, the fact would have been made evident to the most superficial observer by hundreds of her worker progeny displaying the peculiar orange-coloured belt which adorns the Italians, instead of its being apparent only in the person of her successor. The truth is these variations in colour occur more often than is generally supposed. I have probably handled and examined more queen bees, both English and Italian, than any other Englishman, and have several times met with those of the former species whose annulated appearance perfectly corresponded with the one described by "A HAMPSHIRE BEE-KEEPER," but which had not the slightest claim to affinity with the Italian race; whilst, on the other hand, I have seen pure Italians that scarcely differed in outward appearance from the ordinary black queens. Nor is this variation confined to the females; it has already been stated in these columns that pure Ligurian drones are frequently very dark, but I have only recently become aware that drones of the ordinary species may simulate the appearance of Italians. This has, however, been the case in a recent instance in which, whilst destroying the few drones which existed in a second swarm of common bees that I had purchased, I was astonished at finding some among them as distinctly marked as any of my best Ligurians. What rendered this more remarkable was the fact that neither the queen-mother herself nor any of her worker offspring participated in the slightest degree in the gay colours which distinguished their male relatives.—A DEVONSHIRE BEE-KEEPER.

AGE OF QUEENS—BEE SEASON IN SOUTH DURHAM.

I OBSERVE in No. 117 that "A LANARKSHIRE BEE-KEEPER" states that he had a queen for "seven years." Would he kindly say if this is what he wrote, or is it a misprint?

I am glad to say the weather in this part (South Durham) since the 9th of June has been very fine and good for bees, and should it continue a few weeks more I do not think there will be any occasion to take them to the moors.

I think there can be no doubt that the Ligurians are much superior to the common ones. I had a swarm from one of mine in a common straw hive on the 21st of June, and this swarm swarmed again on the 1st July; a half-bred swarm, hived into one of Tegetmeier's observatory-hives, filled it with comb, honey, and grub in twelve or fourteen days, and I have been obliged to put two glasses on, to give them air at top and bottom, and destroy the queen-cells to prevent them swarming in twenty-one days from the day of hiving. I cannot say from experience that the hybrids are equal to the pure Ligurians, but they appear to be superior to the common bees; and this season I find both the hybrids and Ligurians as tame as I ever found the common bees. To preserve them pure you must keep them at a distance from one another, and I have, therefore, moved my hybrids four miles away.—A. W.

APIARIAN NOTES FROM GLOUCESTERSHIRE.

I CANNOT give a very favourable report of the bee-season from this county. The spring was too dry and too cold for honey-gathering. The first swarm I heard of in this neighbourhood was on the 18th May. The second was on the 28th from one of my own old stocks; but breeding has gone on well with the help of occasional feeding. The honey-gathering has been delayed until this time (the 18th June), in consequence of the want of that fine electric weather which often takes place the last fourteen days in May. There are only now about from fourteen to twenty days left for honey-gathering; but the grass is later than usual, and we have no heath and little Dutch clover. In July and August the bees have a bad chance, excepting in heath countries, and where the Dutch clover abounds in July and August, and even latter in some localities. Yesterday (the 19th June) and to-day, incessant rain from N.E. and North.

As I do not admire artificial swarms, I cling to the old-fashioned natural, and, as Virgil describes it, that "Divine instinct" which teaches the bees to increase their number in their own way, which, to my mind, is one of the most wonderful, and by far the most exciting act which these extraordinary insects perform.

Your correspondent from Durham seems to make a shrewd guess that the cold easterly winds in May render the flowers and blossoms nearly useless to the bees. In 1848 we had twenty-nine days of easterly wind, and little or no honey was gathered in that month. The late districts have certainly a chance of doing better this summer, and I have always been of opinion that July and August will be finer and drier than in any of the three preceding seasons.

The exhibition of bees and hives at the meeting of the Bath and West of England Agricultural Show amused me very much, and I was pleased to observe that Mr. Woodbury's hives were greatly admired at the Show, and that his "live stock" made such a "buzz" in the newspapers. It was very agreeable news also to hear that his Ligurian bees had arrived safe, and had been so much admired in Australia. The latter I consider a great feat accomplished, as it is well known that in a voyage of probably more than ninety days, the greatest care must have been taken of those bees to insure success.

I omitted to mention that I hived a second swarm on the 12th, which had hung under a thick shrub all night in the rain. They were very weak, and I gave them some honey; they are now working most vigorously in one of Nutt's old-fashioned boxes.

The last two days I have had a first swarm (from one of last year's) swarm no less than four times; and yesterday (the 17th), no less than twice on the same day, and each time the swarm returned to the parent hive, after half-settling twice on an artichoke plant, and twice on a young pear tree; not the same tree each time. I fear they will not issue out again, as rain has set in.

I can say, certainly, that for half a century I do not remember four consecutive seasons so bad as the past three, including the present, to be ranked almost as unpropitious as any one of the three, so many stocks having been ruined by the cold weather in the spring.

The twelve days' rain from the 5th to the 17th of June caused great distress to many young swarms. In 1849 (then living at Thornbury Park), I lost three stocks

of bees from sheer want, and, of course, inattention. It had been nearly incessant rain for twenty-six days.

Many swarms perished, or became much reduced, by the rains this month (June).

I am glad that the little useful publication "Bee-keeping for the Many" is coming out with additions and improvements. It would be well, as I have often said, that such a book as "Hive-making for the Many" should issue also. It would be pleasing to see cheap bar-hives and Payne's improved cottage-hives with supers and glasses on sale at such prices as would suit the poor cottager. Take the country in general, how few of the farmers, leaving cottagers out of the category, have adopted any of the novelties in hives so often described in *THE JOURNAL OF HORTICULTURE*? In the town of Cheltenham with 40,000 inhabitants, none except the everlasting old-fashioned straw hive is to be seen for sale at any of the hive-shops.

M. Dzierzon's remarks on feeding bees seemed very practical. The bees should only be fed when it is needed, and to those who are watchful over bees, it will soon be discovered when that happens. At the same time, in feeding weak stocks in the autumn against winter, it should be done plentifully, according to their wants and weight.

June 22.—My third swarm came off yesterday (after six times issuing forth), and was hived at one o'clock. Weather cloudy, drizzly, and unsettled, but a warmer temperature, and brood rising.—H. W. NEWMAN, *Hillside, Cheltenham*.

LIGURIAN BEES IN AUSTRALIA.

I AM indebted to Mr. Edward Wilson, President of the Acclimatisation Society of Victoria, for the perusal of various reports from the Australian Apian Society, and journals kept by the gentlemen to whose care the Ligurians were entrusted upon their arrival in Australia, from which I glean the following interesting particulars.

Mr. Sayce, President of the Apian Society, writing under date of the 23rd March says, "It may now be fairly stated that the Ligurian queen bee is a more prolific insect than that with which we have been so long familiar; and I do not hesitate to say that the industry exhibited by these bees is unapproachable by that—great as it is—which characterises the others; or perhaps I should speak more correctly were I to say that the Ligurian bee is a more puissant insect, and that this, added to a most extraordinary gift of scent, which enables it to discover the existence of honey however remote or hidden its receptacle, gives it a superiority in the collection of food. I have also observed that its labours are less interfered with by the weather; for during the recent rains, except when very stormy, the bees went out and returned laden with their stores, apparently quite unconscious or indifferent to the existence of anything which could occasion them inconvenience or discomfort."

Mr. H. Templeton, of George Street, Fitzroy, gives most interesting details in his diary respecting the management of the Ligurian stock entrusted to his care. The bees were shut up by me on the 22nd of September, and underwent a confinement of seventy-nine days, as appears by Mr. Templeton's diary commencing on the 10th December, when he states he "received a hive of Ligurian bees, the property of the Acclimatisation Society, which upon examination proved to be in a most wretched condition, the inner surface of the hive bearing testimony to the great distress which the swarm had endured on the voyage. Found about three quarts of dead bees in the empty box placed under the hive for the purpose of ventilation, which I at once removed. On examining the comb I discovered a few living bees—not more than a large tea-cup might contain, and many of these in a sickly dying state. Left these to gain a little strength before further troubling them." Two days afterwards Mr. Templeton says he "took out the frames containing the combs one by one in order more fully to ascertain their true state. Found on both sides of one comb and on one side of the combs adjoining on each side of it, a number of fine-looking bees, by this time much revived, each having an orange belt round the upper part of the abdomen, and yellow rings distinctly marked back to the point. Discovered the queen—a fine large yellow one—actively running about on the centre comb occupied by the living bees, evidently enjoying excellent health." In two days more fresh-

laid eggs were discovered in three of the combs. From this time all went well. Three stocks of common bees were at different times united to the Ligurians, and with such skill and good fortune were these junctions effected that no fighting took place. Copious feeding was also resorted to, and under the influence of this stimulus a number of drone eggs were laid. Queen-rearing and the formation of artificial swarms were next attempted with similar success; and under date of March 23rd Mr. Templeton says, "The young queens are come to maturity, and are out of the cells. I have supplied two common hives with Ligurian queens, and have, therefore, four hives, two of which I know to be all right, and the two others are hopeful." In a continuation of the journal it is remarked that "the quantity of brood deposited by the two young queens is most astonishing;" and under the date of April 3rd Mr. Templeton says, "I examined a few frames, and found the old queen not only lively and well, but carrying on the breeding as vigorously as ever. Were I to state the number of eggs that that queen has laid since the 10th December last—viz, sixteen weeks, it would appear quite fabulous; no bee-keeper will believe it until he sees them—it is more than double the number a common queen could produce in the same time."

The diary ends on the 11th April, before which time the writer announces his possession of four royal cells, which being from the brood of a young queen would produce grand-daughters of the old queen that came from England. He also states that he has twelve stocks in frame-hives, of which four have yet to be supplied with Ligurian queens.

It may be remembered that the first venture was made with four stocks. All reached Australia alive, although with greatly reduced numbers; but one I believe afterwards deserted its hive. Of the remaining two, the one under the care of Mr. Sayce, the President, has well filled its hive with honey, and the other under the care of Mr. McMillan has formed a strong stock.—A DEVONSHIRE BEE-KEEPER.

BEE SEASON IN HAMPSHIRE.

THANKS for your acknowledgment of my letter. I think if there was a Ligurian hive within reasonable distance of my abode I should have heard of it. I will make more diligent inquiry—it may serve to measure the flight of bees.

We have between us made a mistake as to the number of years I have been a bee-keeper. I began in 1838, a most unfortunate time as regarded the north. I do not remember that we had a good bee year till 1842, and as I tried "no end" of experiments my disasters would fill a book. As I grew older I grew wiser; and of late years few have had more honey than I have taken. Yorkshire is a very good county for bees. They breed more, make a great deal more comb; and of course when a season is propitious three or four stone is nothing to boast of; indeed, some of those from the moors will weigh on their return "well on" to six stone. The hives are so small in Hunts and the Isle of Axholme that you could not work with them in Yorkshire, and *vice versa*. Having only been two seasons in Hampshire I judge more from the size of the hives I see in the cottagers' gardens than from actual experience.

This year the season is so good that few of my neighbours can reap the harvest they ought; and in trying remedies by cutting the tops out of old hives to make "grafts" they are making many "mulls;" and this would seem to show that grafts, or "ekes" as we called them in Yorkshire, are not much in use here.

I have not seen my striped beauty since I wrote. Her subjects began drone-killing just then, and I expect her guards may have kept her out of harm's way. Now the luck winnow is deserted. The bees are very few in number, but they have killed all their drones, are carrying pollen, and are very pugnacious, from which I gather that she is alive and well.—A HAMPSHIRE BEE-KEEPER.

OUR LETTER BOX.

SHEFFIELD POULTRY SHOW.—The prize birds single Spanish cock, Carrier Pigeon cock, and variety Pigeons belong, we said, to Mr. Smith of Sheffield, but that gentleman lives at Walsall.

PICCOLI'S *(A Subscriber)*.—Write to Mr. Tegetmeier, Muswell Hill, London, N., and ask his advice.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 73.5°, and its night temperature 51.6°. The greatest heat was 92°, on the 25th, 1844; and the lowest cold, 31°, on the 25th, 1860. The greatest fall of rain was 1.37 inch.

CENTAUREA RAGUSINA AND ITS PROPAGATION.

SEVERAL years ago I ventured to bring this lovely plant under the special notice of all who were interested in flower-gardening, as a subject which was every way likely to be of great value in combination with the far-too-limited collection of plants which are generally considered available under the present fashionable style of flower-gardening.

The high opinion which I formed of this *Centaurea* whenever I saw a well-grown plant of it has not been in the least altered, but, on the contrary, has been more than warranted by the beautiful effects which have been produced by its extensive cultivation in several flower gardens, as well as by its general cultivation in pots for all the various methods of decoration which are popular at the present time; but it unfortunately happens to be a plant with which the trade has not been very successful in getting up a stock equal to the demand which has arisen for it.

I think it was Mr. Robson who recently referred to it as a plant which was likely to be much more thought of and extensively used as soon as its adaptability became better known: and the wonder is that it has not before now been brought more prominently before the public, and popularised by the great schools in such matters around London, where I was surprised to meet with so little of it last summer. It is considered, and has been found even by some of the sharpest of the trade in such matters, a difficult subject to increase rapidly; and in instances which have come under my own ken some nursery propagators have failed with great batches of cuttings; and partly on this account I have heard it several times remarked, that any one who could have offered a large stock might have made "a good thing" of it. I have never found any difficulty in striking this plant under ordinary circumstances; and I will briefly detail the mode adopted, and refer to the way in which it has been used in the flower garden here. Let it be supposed that a few plants in pots are all the stock in possession at this time. If strong stubby plants in six-inch pots, they are shifted and placed in the open air in the full sun. By the time when plants are generally housed in autumn they will have formed fine, large, bushy plants; and although this *Centaurea* is almost if not quite hardy, it should not be left out beyond the 1st of October, because, if subjected to drenching rains, its soft woolly foliage is apt to damp-off at the centres of the plants. To keep it in the best possible condition to

afford fine fresh cuttings in spring, it requires to be kept on a dry airy shelf, and to be very sparingly supplied with water—just sufficient to keep it from drooping is quite enough, for it is a plant very apt to damp-off in winter if kept damp and crowded among other plants. In spring they are found with a quantity of cuttings studded all round the bottom part of the plants; and if these cuttings are short and without a bit of clear stem about a couple of inches in length, the plants are put into heat, and there the cuttings soon elongate, and are cut off with a sharp knife almost close to the main stem of the plant. They are prepared in the usual manner and dibbed into eight-inch pots, which are very carefully drained and filled with silver sand. The pots are plunged to the rim in a pit where *Verbenas* and other bedding plants are struck. They are watered just sufficiently often to keep them from drooping, and the foliage kept as dry as possible. They root in about twenty days; and as soon as they form roots about an inch in length they are potted-off into three-inch pots.

I have always observed that they never thrive well if left any length of time in a strong heat and in pure sand before being potted-off. They are by no means particular as to soil: half loam half leaf mould does very well. As soon as they make roots to the bottom of the three-inch pots they are transferred into six-inch ones and placed in a cool frame or house, and by the end of April they are fine strong plants ready for planting out. The first week in March is quite early enough to take the first batch of cuttings: and soon after the first lot are taken from round the lower part of the parent plants, the second lot will be ready for striking. Those cuttings with the longest and most firm stems invariably strike the soonest, and a far less percentage of them damp off in the cutting-frame than in the case of those that are short and softer in the stem.

It is a very rapid-growing plant, and cuttings may be struck as late as the end of April for the purpose of being planted in the open ground. Later-struck cuttings form beautiful little plants in six-inch pots for dinner-table decoration, as well as for vases and general decoration.

There is another method which I have adopted with less success—namely, to put in cuttings in autumn, and place them in pans and boxes in a dry, cool, airy house: in this way a great many will callus through the winter, and with a gentle bottom heat in spring will root freely. This is just as is often practised with late-put-in cuttings of *Scarlet Geraniums*, and meets with very nearly the same success. I prefer spring propagation, it being more certain, and the trouble and care entailed are less than by adopting the other mode. I have never found autumn cuttings put into bottom heat immediately do much good, but on the cool system the majority of the cuttings do very well.

To keep up a stock I think it much the best way to keep a few plants all the summer in pots—they come in useful for many other purposes, and to take cuttings from the planted-out plants sadly mars their appearance, while, on the other hand, to lift the old plants is a laborious

affair, as they form such immense bushes; and unless potted-up earlier than they can be spared from the flower garden, they require much more room and care than can be afforded them in quantity, and except under very favourable circumstances they do not bear the lifting well.

Three years ago I planted out upwards of four hundred plants; and one of the most effective and novel combinations I ever saw was *Centaurea* and *Perilla* plant for plant. The bed was a diamond bed, forming the centre of a cluster of beds on grass. It was raised to a cone 5 feet above the level of the turf. I well remember being severely found fault with by some fair critics when the bed was newly planted. The surface was paved over with blue bullet-like stones from the shore, and it certainly looked odd; but by the time the stones were all hid, those who had most severely criticised the bed had begged a thousand pardons for their mistake. The *Perilla*, of course, was the taller by a few inches, and, viewed from the distance, it was considered the best imitation of rockwork. The same season another bed was planted with blue *Lobelia*, and then the *Centaurea* dotted all over it, so as to leave a ground of blue running among the feathery foliage of the *Centaurea*.

When *Lobelia speciosa* has been used for groundwork in panel-borders, a single plant of *Centaurea* has been used for the panels; the blue and it form a very chaste and pleasing combination, and the two plants are thoroughly distinct in character. This year it is used for panels alternately with *Christine Geranium* where the groundwork is *Lobelia* speckled thinly with *Gazania splendens*. In another wide border it is planted in the centre of panels of *Purple King Verbena* where the groundwork is a deep scarlet. The *Centaurea* is raised quite above the level of the panel of purple; and even at this date the effect is very pleasing, and will be more so as the purple fills fully up and becomes more massive. Raised in the same manner it forms a beautiful centre to a cone of *Scarlet Geraniums*. In one instance or two it has been surrounded with a circle of *Christine* in the centre of *Tom Thumb*. As a vase plant edged with *Lobelia* it is most lovely. It also looks well in vases edged with dwarf *Scarlet Geraniums*.

As a plant for placing in gold vases on the dinner table it is most acceptable, and stands such work well—in fact, this is one of the most useful plants of the day. It would be a great step in the right direction if it were possible to plant over flower gardens to a larger extent with plants diverse from and more picturesque in character than the everlasting and monotonous masses and lines of *Geraniums*, *Calceolarias*, and *Verbenas*; and this want is being more largely acknowledged every year, and the more so as taste becomes more refined and alive to the fact that beauty consists not alone in gaudy colours, however strikingly in contrast or nicely harmonised.

DAVID THOMSON.

TETRATHECA VERTICILLATA CULTURE.

In answer to "J. M." we reply that the plant is rightly named. Full directions for culture were given in a previous volume. It requires when young to be grown chiefly in sandy peat, well drained, and never allowed to become very dry. It also requires a temperature of from 45° to 48° in winter, with a due proportion of air; and in summer, if the top is fully exposed to the sun, the pot should be sheltered by plunging or shading, or placing in a double pot, as, if the pot is fully exposed, the roots are apt to be injured. It generally blooms most freely in early spring and summer; and that gives, as it were, the keynote to its culture. Left to itself, it soon becomes weak and rambling; and therefore, to secure anything like compactness, rather free pruning must be resorted to when the plant has nearly finished blooming, taking care, however, not to cut farther back than the current year's wood, as it breaks badly from older wood.

After pruning, keep the plant rather dry, cool, and quiet until there are signs of breaking; then put in a cold pit or other place; and, with the exception of giving more air, treat the plant as to syringings, &c., much the same as was recommended the other week for *Epacris*. As the young shoots grow more air must be given; and if in fine days in September the plant should be exposed to the sun fully, the more ripened and short-jointed will the wood be, and

the more covered will it ultimately be with bloom. What potting the plant requires should be given when the young shoots are about 2 inches in length. After that repotting watering should be done very carefully, so as not to saturate the new soil, slight syringing and shading being resorted to in preference until the roots are working in the fresh soil. As the plant gets large, and an eight-inch or larger pot may be necessary, fibry sweet loam in the proportion of a third or so may be added to the peat, along with some pebbles, broken pots, and nodules of charcoal to keep the soil open.

Cuttings of the points of the shoots will strike at any time, but the best cuttings are thinnings of the young shoots about 2 inches long formed after the regular pruning. For these a small pot—say a small 60, should be three-parts filled with drainage with a slight covering of rough peat and sand, and a surfacing of half an inch of pure silver sand. Place the cuttings round the sides of the pot, the heads of the cuttings pointing inwards. Water well, and then place the small pot inside of a five or six-inch pot, stuff between with moss, cover with sand, and in the space between the two pots place firmly a bell-glass with a conical head, and set anywhere so as to command a temperature of from 50° to 60°, and where shade can be given when necessary with a piece of paper over the glass.

The cuttings, with the glass down, will stand a good deal of sun morning and evening. If kept too close and shaded they will draw very spindly and weak. To neutralise that, and also prevent the cuttings damping, move the glass a little at night, and as soon as the cuttings callus freely take it off altogether at night, if there is no likelihood of the tender cuttings being dried from being placed near a heating medium. To prevent damping on the one hand and drying up on the other, it will be found preferable to keep the place round the cuttings moist, and even to water the space between the two pots instead of watering the little pot in which the cuttings are placed. We have not grown the plant lately; but, by the above mode, we have found every cutting strike and grow freely. In potting-off we first placed four round the sides of a small 60-pot, using chiefly sandy peat with a little charcoal about the size of bird-shot, watered, kept close, and shaded from bright sun until they were growing freely and each plant was forming a nice little mass of roots, when each of the four plants received a single pot.

The plants were frequently stopped by pinching-out the points, and brought under the general routine of management. In potting place the drainage as directed the other week, so that wherever the plant is placed worms cannot get in from beneath, as the plant will not thrive with worms about the roots; and, though they may be dislodged with clear lime water, we always found the plant disliked such applications, or even hard well water of any kind. If rain water cannot be had, and spring water must be applied, it should stand in the sun twenty-four hours before being used.—R. F.

GRAPES AND MELONS FAILING.

THE Grapes in my hothouse I perceive are drying-off; their appearance a few days ago was luxuriant. I have been speaking to a gardener about it, and he says my head man gives them no longer any water, contending that, the Grapes having swelled, the Vines should be dried-off. Common sense, one would think, indicates a totally different plan; for when the plant requires the greatest nourishment, then the greatest moisture should be administered. This is my theory. Am I right?

From precisely the same cause, I think, my Melons are good for nothing, and not bigger than a cricket-ball. My man may be right: if he is, it strikes me as the greatest anomaly in nature. Another thing I should mention in regard to the Melons—the vines run all over the frames, and would get out if they could. Does not this exhaust the plant?—E. B.

[We feel that it is a very delicate matter to pronounce upon the fitness of a certain treatment, when it is a matter of dispute between a gentleman and his gardener, where the data given are necessarily so meagre. When Grapes are dead ripe it is often advisable to keep the borders rather

dry, as a little excess of moisture is apt to cause the berries to crack. If the Grapes were merely swelled, not ripe, then extreme dryness would be apt to make them shrivel and dry up. As they seemed so luxuriant a few days ago, we could not be positive that this was the cause, unless assured that the roots were dry. In such weather they might soon become so, if the roots were shallow, and no mulching or watering given. If the roots were moderately deep, we should be inclined to judge that dryness at the roots was not the reason; but to assign it to a very dry and hot atmosphere inside. As a general rule, however, we should never think of "drying-off" the Vines until the fruit was not only ripe but mostly cut. When fully ripe, we could not deluge the border, but we should rather wish it to be dry until the fruit was pretty well gone. A good theory may become a nuisance and a mischief when too hard driven. In such dry burning weather, even if Grapes are ripening, a little moisture in the house from syringing walls, stages, floors, &c., will prevent shrivelling and drying. In cold, dull weather, such treatment would help the berries to crack and rot. If the Grapes are merely swelled, not ripe, watering at the roots if dry will be all in their favour, and just a moist condition in opposition to dust dry should be the state of the roots until most of the fruit is cut. Even then some tender kinds are easily influenced by a moist or very dry atmosphere. In moist, muggy weather, therefore, it may be advisable to put a little fire on and give plenty of air; and in very dry weather it may be just as necessary slightly to damp the atmosphere of the house, by syringing floor, paths, &c.

We fear that there may have been something of the same extreme as respects the Melons, only the extra luxuriance makes us doubt a little. If there was a good depth of soil, and that was well saturated after the Melons took hold, and the surface stirred afterwards, we have frequently had fine crops of Melons that never again were visited by water. These were cases in which the heat was more important than moisture, and when we knew there was plenty of moisture to swell and ripen the Melons. In general cases, Melons just require as much water as most other plants—quite as much as the Cucumber, until the ripening process approaches. If there is an exception, it is the importance of having a dry atmosphere when the plants are in bloom. That is best secured by having the surface of the bed dry then. Of course, if the soil, as a whole, were dry, we should not expect the fruit to set, and if set, we should not expect them to swell. When the swelling commences we like the soil to be moist. If the weather is unfavourable, and a moist surface would cool the place too much, then we would moisten the bulk of the soil, and leave the surface dry. In fine sunny weather there will be no harm in watering the bed in the usual way. A dry surface is essential for flavour, if the fruit is ripened in dung-frames; but the soil containing the bulk of the roots should not then be dust dry, and neither should it be deluged. Except when it is setting and ripening its fruit, the Melon needs as much moisture as a Cucumber, and not a great deal less than a Cabbage. It is only as the fruit approaches maturity that the extreme of dryness is a matter of importance. When plants are grown in pots, or in narrow beds, and trained to a trellis, and the fruit suspended under the foliage, but considerably above and free from the bed, then even surface dryness of the soil is a matter of less importance for securing flavour. In all cases where the fruit is merely swelling, we should consider a very dry state of the soil unsuitable, and calculated to ripen the fruit prematurely before it had gained half its usual size.

The slight doubt as to this extreme of dryness we find in the "another thing," as to the vines being so luxuriant and trying to get outside, the frames being full of them. This is hardly compatible with extreme dryness of soil, unless, indeed, the roots have gone in search after moisture beyond the soil, and are revelling unchecked in rich rotten dung, or something of that kind. In such a case the plant will not become exhausted—quite the reverse; but it will most likely be a very successful instance of luxuriance *versus* fruitfulness. Such luxuriance of bine speaks of the plant thriving, but then it also speaks of want of concentration for a definite purpose—namely, fruit. Leave such luxuriance unchecked, and the plant in its eagerness to grow and

expand may forget all about the fruit that needs elaborated sap to swell it and give it flavour. When a plant in a frame is thus a thicket of shoots, more than half the foliage is uninfluenced by the sun, and, therefore, hurtful rather than otherwise. If not curtailed, it would be a good thing for the plant if the frame were raised, and the Vines allowed to go outside. Melons dislike cutting and slashing. The best mode is to disbud at first, and pinch merely afterwards. In such a case as we presume the present to be, a severe cutting and thinning would do more harm than good. The check given to the mere growth would act on the fruit, and very likely arrest its swelling. Shorten all the shoots of the small fry at once by merely picking-out their points, which will thus give a gentle check to mere growth of wood, so that the fruit may have the benefit of the nourishment which would otherwise have been appropriated to the production of wood, and then take a little foliage away day by day, until at last there are few leaves that cannot be fully exposed to the light and air when you give it. If there is plenty of heat, leave a little air at the top of the frame all night, and give as needed during the day. If thus kept cool at night, the plant will rejoice rather than otherwise in a high temperature during the day. But for the enervating influence of a high close temperature at night, there would be less trouble with airing and shading during hot sunshine.

Such are a few random ideas, the results of some experience; but we by no means think they will clear up thoroughly the difference as to opinion between "E. B." and his gardener. If they help to do so, or to establish the principle that one system may be very good, if thoroughly carried out, whilst two good separate systems if blended and mixed will often produce mischief and failure, we will be more than satisfied. Without understanding the system on which a man works, it is not an easy matter to say that his practice is wrong. Nothing could seem more different than watering Melon plants only at planting time, and watering on an average, say, once or twice a-week, and yet precisely similar results may be obtained in both cases by a little diversity of detail. Only this much we may say, that the man who strikes out a fresh path for himself whilst in the service of another, must make up his mind that he must also secure pretty fair success. Many a servant has lost a good master because, right or wrong, he would have his own way. Many a master has lost a good servant because he would not exercise a little forbearance.]

STRAWBERRY-GROWING.

I CAN from experience safely recommend "H. C. K.'s" mode of mulching Strawberry plants with a liberal quantity of horse-droppings; but I cannot bear out his assertion that it is possible by this treatment to keep "one piece of ground under Strawberries for sixteen years without the slightest loss of either quality or quantity." As he speaks from experience, will he kindly inform your readers more clearly if he means that he has had for sixteen years good crops from the same old crowns, without renewing the beds with fresh plants? Surely he can hardly mean this, for it is against all recognised theory or practice. His system, if correct, will be a perfect blessing to the host of amateurs, who with their odd man or boy have to rack their wits how to renew their Strawberry-plots every three or four years.

Whilst on this topic I venture to say that I have accidentally found that the waste fibre from the cocoa mat and brush factories is an excellent protection for the ripening Strawberries instead of straw or grass. It keeps the fruit clean and dry, does not harbour vermin, and with care lasts many years. It was sent to me by mistake for the potting fibre; but it is now the right thing in the right place.—W. X. W.

PROTECTING STRAWBERRIES FROM SLUGS—COTONEASTER MICROPHYLLA.—Some of your correspondents have been inquiring how to protect Strawberries from slugs. I am much tormented with them, and have found dry sawdust from my sawmill a complete safeguard. In addition to the uses lately mentioned for the *Cotoneaster microphylla* you might suggest the grafting it on Thorn stocks about 4 feet

high, and training it to a round head. It has a beautiful appearance in the autumn. It is the only plant I know which naturally grows towards the north, and, therefore, if planted against a wall with a south aspect will always keep close to it without nailing.—AN IRISH SUBSCRIBER.

NOTES ON NOVELTIES AT SAWBRIDGEWORTH.

THANKS to the orchard-house system, we have been enabled to make the acquaintance of several novelties this season which without the aid of such an appliance we might have lived all our days in ignorance of. Whatever may be said for or against orchard-houses depends entirely upon the point of view that the advocates or opponents of those structures view them from. A great deal has been said in our pages lately on both sides, and it cannot be denied but that much ability has been displayed by the writers by the way in which they severally supported their views on this subject. It is not our intention at present to support the views of either party, but simply to record such facts as have come under our own observation, and to take advantage of the new information we have obtained—information we should have despaired of ever having got except for this mode of cultivation.

For some seasons past Mr. Rivers has had in operation a glass structure which he calls a Cherry-house. It is in every respect the same sort of thing as the ordinary orchard-house; but being devoted exclusively to the cultivation of Cherries in pots, he has designated it by this name.

Like ourselves (and, oh! how often have we felt it), Mr. Rivers had felt the disappointment arising from endeavouring to prove new Cherries on trees grown in the open ground. It mattered not how much trouble was taken with them; however skilfully pinched and pruned, or artfully fashioned, they may have been; or however profusely they may have blossomed; if a cruel May frost did not devastate the promised crop, the birds devoured it ere it was half ripe. Years passed on, and no progress in knowledge was made, till in pure desperation the trees were crammed into pots and taken for refuge to the Cherry-house. And well have they repaid the trouble taken with them. The trees are beautiful pyramids 3 to 3½ feet high, and literally studded with fruit of the greatest beauty and finest flavour. We would strongly advise our readers to see them. Among the new varieties we observed as possessing very great merit, and which cannot fail to become permanent in our collections, were the following:—

EARLY RED BIGARREAU (*Bigarreau Rouge de Gouben*).—The fruit is large, about the size of the ordinary Bigarreau, but of a decided heart-shape. The skin is bright red and transparent, like that of Belle de Choisy. The stalk is 1½ inch to an 1¾ long. Flesh firm, rich, sweet, and excellent.

This is a very excellent early Cherry, quite ripe before the old Bigarreau begins to colour. The tree is like a Duke in its habit of growth, but the fruit is so decidedly heart-shaped, and the flesh so firm, that it must be classed among the Bigarreus.

EARLY BLACK BIGARREAU.—This is a fitting companion to the preceding, and ripens at the same time. The fruit is large, distinctly heart-shaped, as large as the Bohemian Black Bigarreau. Skin jet black. Stalk 1½ inch to 1¾ long. Flesh dark purple, firm, richly flavoured, sweet, and excellent.

Mr. Rivers received this from the Continent under the name of Bigarreau à gros fruit couleur de chair, which is evidently a misnomer.

LUIGIO'S BIGARREAU.—Fruit large and perfectly heart-shaped, terminating at the apex in a sharp point, with a slightly marked suture on one side. Skin shining, of a fine bright red colour, which is evenly distributed over the whole surface, except that it is a little paler on the shaded side. Flesh pale yellow, very tender and melting, much more so than Bigarreus generally are. A delicious early Bigarreau, ripening just after the Early Red Bigarreau.

BOHEMIAN BLACK BIGARREAU.—This is a fine large Cherry, of a roundish heart-shape, even and regular in its outline, and flattened a little on one side, where it is marked with a faint suture. Skin jet black and shining. Stalk dark green, remarkably short, being not more than 1½ inch long, stout,

and rather deeply depressed. Flesh quite black, firm, but not crackling, juicy, richly flavoured, and delicious.

This is ten days earlier than the common Bigarreau. It is a splendid Cherry.

DROGAN'S BIGARREAU (*Bigarreau Blanc de Drozan*).—This is a very early form of the Bigarreau, being quite shrivelled when that variety is only just ripe. It is perfectly heart-shaped, rather pointed at the apex, and flattened on one side. Skin yellow, mottled and flushed with red on the side that is much exposed. Stalk 1½ inch long, stout. Flesh firm, sweet, and richly flavoured. A very desirable variety.

TRANSPARENT.—This is said to be the result of a cross between Reine Hortense and May Duke, and it has preserved in the form of the fruit that of the latter parent. The fruit is above medium size and oblate, with a bold style-mark on the apex, and with a very faint suture on the side. The skin is thin and transparent, showing through it the netted texture of the flesh, and of a uniform pale red colour all over. Flesh melting, tender, sweet, and delicious. This comes among the Red Dukes, and is allied to Belle de Choisy.

DECHENAUT is another of the Red Duke class. The fruit is large, roundish heart-shaped, broad at the stalk, rather flattened, and marked with a faint suture on one side. Skin bright cornelian red, and shining, becoming darker red when quite ripe. The stalk is 1½ inch to 1¾ long, inserted in a wide and deep depression. Flesh tender and succulent, with the May Duke flavour. This is a fine large Cherry, well worth cultivating.

These were among the most attractive of the new sorts of Cherries. There were many more, some really new and others old friends with new faces, or, rather, with new masks; for the new names under which Mr. Rivers imported them were merely masks to palm-off old sorts, and which but for the orchard-house might have continued undetected for years to come.

We have heard a great deal lately about the difficulty of fruiting Apricots in the orchard-house. There seems none about it at Sawbridgeworth, for in one of the large orchard-houses there are some splendid large trees completely studded with fruit. The whole secret, if secret it is, consists in ramming the soil in the pot when the tree is planted as closely as it is possible to pack it. This soil should consist of tenacious loam and dung, and the surface should be mulched in summer with very rich soluble matters, such as malt-dust and horse-droppings saturated with very strong liquid manure. Among the novelties in this department we observed the two following, which will doubtless prove valuable acquisitions:—

EARLY MOORPARK.—This came from the Continent under the erroneous name of Angoumois Hâtif, which is a totally different thing. The fruit of the Early Moorpark is roundish, inclining to oval, with a very deep suture on one side extending from the base to the apex. Skin yellow, mottled and dotted with crimson on the exposed side. Flesh in all respects resembling that of the Moorpark. Stone oblong, with a covered channel along the back, which is perversive. Kernel bitter. This ripens three weeks before the Moorpark.

SARDINIAN (*De Sardaigne*).—This is a small early Apricot, not much larger than the Red Masculine, but equally as early and much superior in flavour to it. The skin is white, but where exposed to the sun it is spotted with a few crimson spots, and sometimes has a flush of red. The fruit has a deep suture on one side. The flesh is very juicy, with a sprightly sweet flavour, which is very agreeable. The stone is very small, not more than half an inch long, with a covered channel, which is perversive. Kernel bitter.

The tree is a great bearer, and ripens its fruit as early as the Masculine. This season it was ready for use in the orchard-house on the 28th of June.

The pot-fruit-tree culture in this vast establishment is truly marvellous. We observed house after house literally crammed with Peaches, Nectarines, Apricots, Plums, Figs, Cherries, and Vines, all in preparation for the winter campaign. One mass of two thousand of the new Victoria Nectarine, which is to be sent out this season, particularly struck us by the health, vigour, and uniformity of their growth, and the neatness with which they had been worked so close to the soil. But there is a new idea Mr. Rivers is about to introduce, and to which he attracted our atten-

tion. It is no other than what he calls "Japanese trees"—Apples, Pears, and Plums, or, in fact, any kind of fruit trees, grown in No. 24-pots. There was a lot of them not larger than a decent-sized Geranium laden with fruit, and their dimensions are limited by a constant system of pinching. Judging from what we saw on this occasion, the idea bids fair to become popularised, as they are grown, not under glass, but simply plunged in rows on a bed of dung, leaves, or other fermenting material from which a steady, gentle, genial heat can be obtained. There is no covering whatever required; and those who complain of the constant watering necessary in the houses will have an opportunity under this system of indulging in the amusement of growing pot-plants without so much labour in watering as there is in the house-system.

ROSES.

MESSRS. FRASERS' NURSERY, LEA BRIDGE ROAD.

A visit to this extensive nursery is well repaid at this season of the year. Messrs. Frasers' Roses are now in high condition, and among them are to be found the very best varieties in cultivation. The soil seems particularly adapted to the Rose; and although the time of flowering may be a little later than in other nurseries, the size and colour of the individual flowers cannot be surpassed. Every Rose-grower should visit this collection and make notes of the new and distinct varieties. There is much advantage in purchasing Roses after seeing them in bloom—it prevents that frequent disappointment which attends the purchase made from description.

Messrs. Fraser have also now in bloom a large and interesting collection of Fuchsias. Much is it to be desired that our Fuchsia-growers would pay them a visit at this season. They would learn that the new varieties can make good specimen plants; and if they could only see Comet, Lord Warden, Elegantissima, Marginata, Signora, Hermine, and the double variety True Blue, as grown in this establishment, they would immediately introduce new and excellent kinds into their collections. The amateur who cultivates the Zonale Pelargoniums will find in this nursery some excellent new French varieties, novel in colour and perfect in form. Much is it to be desired that this beautiful class of plants should receive more attention.

Among other interesting plants the Messrs. Fraser have a very large collection of single and double Petunias. These are planted out in a bed, and seem well calculated to be very effective for that purpose. Several of the double varieties are as large as the Rose Baronne Prevost when fully expanded, and some of the striped varieties are exquisite.

Should any person be induced to run down by the Eastern Counties line (making the journey in twenty minutes), let him be sure to ask to see the splendid collection of German Stocks, and he will agree with me that they alone are well worthy of the journey.—X.

HOT-WATER PIPING REQUIRED FOR HEATING A VINERY.

WHAT quantity of pipe will be required to heat a vinery 70 feet long, 14 feet wide, 5 feet high in front, and 12 feet at back? It will be in three divisions, one being for early forcing?—CUMBRISSENSIS.

[Supposing the first house to be 23 feet, for that you will need 140 feet of four-inch piping for early forcing; for the second about 100 feet; and for the third or late house, and to be kept so, about 80 feet. If all the 70 feet were intended for Grapes from July or so, then about 250 feet would do. It is best, however, to err on the side of having enough, as then you might change your houses gradually at any time from late to early. Deficiency of piping just means waste of fuel, and, therefore, is seldom true economy.]

SHOW RANUNCULUSES.—It may be interesting to some of your readers to know the names of a few choice sorts of Ranunculuses that have appeared in successful stands at exhibitions this month. The following notes were made at Oxford and Wallingford of flowers, which well deserve the

cultivation of lovers of this interesting flower. Among edged flowers on white grounds I noted fine specimens of Kilgour's Queen, Lifey, and Herald. Edged on cream or buff grounds, Linden and Terpander. Edged on yellow grounds, Eva, Sir W. Hoste, Delectus, and Festus. Mottled flowers, Melancthon and Coronation. Spotted flowers on yellow grounds, Pertinax. Self-colours, Apollo, Bouquet, Marquis of Hereford, Eliza, and Suranné. Two or three edged varieties of seedlings were produced, but without names, so that there were no means of identification. I understand the promise of vigorous bloom was good in the early part of the season, but the frosts of April and May did much injury.—X.

STUDLEY ROYAL.

(Concluded from page 29.)

Now for the gardens. Introduced by a friend to Mr. Clarke, the clever gardener, I was privileged with a view of his department, for the pleasure grounds form a department of themselves.

The mansion is situated in the outskirts of the park and near to a public road. Although much improved by its present owner, it is not sufficient either in size or architectural beauty to harmonise with the surrounding scenery. The outline of another mansion close by, partly built some years ago, still remains, and is used for a variety of purposes. In front of the mansion a large new garden, or rather series of gardens, in the terraced style, with geometrical beds, some on grass, others on gravel—after the designs of Mr. Thomas, of London—was fast approaching completion. The plans are simple but very chaste, and harmonise well. The parts are not so intricate as in many of a like kind, nor so toy-like as the polychrome figures or parterres at the Royal Horticultural Gardens. The finished part of the garden was very effectively planted, and the plants being large, showed the various edgings, ribbons, and masses well considering the earliness of the season (June 6th). In company with Mr. Clarke I made for the kitchen garden, and in the chat by the way I found he is one who looks on all the brotherhood of Flora as friends. Being a perfect stranger I had no idea of putting on paper what I saw; but, what with the kind reception and the known celebrity of the place, I became bold enough to jot down a few things seen and heard.

The kitchen garden is situated some distance from the mansion, and is separated from the park by a low wall. It is divided into several compartments by walls, and appears to have been made at different periods. The principal garden, however, is a parallelogram, divided into quarters in the usual way, and the walks are bordered with fruit trees. It was well stocked with vegetables, and the beds of Asparagus, though very old, bear well. The north wall of this garden is covered with fine Peach trees loaded with fruit, testifying that there is no necessity for an orchard-house, even in the north, to secure good Peaches. There is more fruit on one of these trees than in any orchard-house I have ever entered. The leaves of the trees, however, were somewhat scorched, as if some caustic solution had been applied to them; and, what was most remarkable, no insect had, I was informed, infested them: consequently no solution likely to cause the leaves to blister and wither had been used. In other respects the trees were very fine.

At one end of the garden is a double row of pits, formerly Pine-pits, heated by hot water and dung-linings, but now used for plants, furnishing cut flowers in winter and plants for decorative purposes, besides bedding plants, &c. Mr. Clarke speaks highly of Una and Beadsman Geraniums as furnishing early blooms for cutting.

Another pit, considerably below the level of the ground, is planted with Vines, which apparently are very old, but they annually produce good crops.

In an adjoining house were some very fine Cucumbers of a variety named Scott's Superb, and, whether a local or old variety, it certainly is not in general cultivation. It is not a very abundant bearer, but moderately handsome and large, hanging a long time without turning yellow, besides being a good winter-fruited variety. The house in which it is growing is used for propagating and many other purposes.

In another house—a narrow one—I noticed some well-grown Vines in pots. The pots containing the Vines were placed along the front and the canes trained up the roof, but so closely together as to cover the whole of it. By this plan double the quantity of fruit is obtained, and early Grapes ripen more surely than when the roots are outside in a colder medium than the canes. Each Vine in a pot is allowed to carry from six to nine and even twelve bunches, and finer Muscats could not be wished for. The Muscat of Alexandria, White Muscat, Canon Hall, and Tottenham Park Muscat, all do well; and the last, although in every respect like the White Muscat, is yet a much freer setter than any of the Muscats and not so liable to spot as most of them. Mr. Clarke, who has had ample opportunities of comparing the Vines in all stages of their growth, says the Tottenham Park is as free a setter as a Hamburgh. The bunches are stiffer, and the footstalk of the berry is considerably stouter than that of the Muscat of Alexandria. Another kind, under the name of White Muscat, is in no way different, I think, from the Muscat of Alexandria; but as I have seen it elsewhere under that name, I may be wrong.

In some pits were Peas in full bearing, a row each of Sangster's and Eclipse; the first dish, however, had been gathered three weeks previously.

The southern division of the garden is occupied by a pond with an island in the centre, and near to it is the approach from the park, and a neat little flower garden, mostly occupied by herbaceous plants; but I understand a re-arrangement of this garden is contemplated.

A barn-like building in its external appearance is used for the growth of Mushrooms, and has in its interior a bed in the centre on the floor, and two shelves, or beds, all round. These shelves, or beds, are formed in a very substantial way, the sides being of iron, and are about 15 inches deep and 5 or 6 feet wide, with iron-grated bottoms. Two beds were just coming into bearing, and promised a prodigious crop. I understand this house produces a succession in abundance of very fine well-flavoured Mushrooms.

All the garden walls are covered with fruit trees in good order, and bearing well. A Pear that Mr. Clarke speaks very highly of, the crops of which are enormous, is Hacon's Incomparable. It is a large melting Pear, in use for dessert from November to January. A black Mulberry on the wall adjoining a Fig-house has the branches trained perpendicularly downwards, and annually produces good crops. Besides the walled-in portion of the garden mentioned there are other two compartments, in one of which was a Fig-house, with Vines on the rafters. The Fig trees are planted inside the house, in narrow borders at the back, about 1 foot wide and 2 feet deep, and the trees trained to the back wall. The fruit was large, plentiful, and ripening. The variety was, if I mistake not, the Brown Turkey, the best of Figs for any purpose whatever. The narrowness of the borders would cramp the roots, and unless this is the case Figs make too much wood to bear well. The Vines were only newly planted, but Vines in pots were bearing splendidly, thus making use of the house until the young Vines are of sufficient size to bear. I incline to the opinion that Vines can be grown equally well in pots as planted out, and better where the border is outside on a cold wet subsoil. The house can then be used for a variety of purposes in winter; but where the Vines can be planted in the house or the border heated it saves time and labour to have them planted out. In this house I noticed a very fine plant of *Coleus Verschaffelti* in preparation for planting in the flower garden to form a centre bed. It was more than 6 feet across, and by planting Golden Chain Geranium round it, edged with *Amaranthus melancholicus ruber*, it was expected an effective bed would result. Should Mr. Clarke carry out his idea and find it answer, I hope he will favour this Journal with a notice.

Two vineries adjoin the Fig-house. The Vines, however, had been cut down and grafted with newer and better kinds than the old ones, and beside each Vine was a Vine in a pot. The grafts were just beginning to break. Inarching, however, I consider a better way of working the Vine than grafting. Inarching can be done at any time, and a much stronger cane can be had the first season than from grafting, however well done.

Here, again, were more Vines in pots bearing profusely.

The pots were only 9 inches in diameter; and by placing them about 2 feet apart, and bringing the canes of both pots together, they were tied in the shape of a half-circle.

Some of the pots, or arches, had twelve bunches, and one being White Frontignan and the other Muscat Hamburgh, they were, indeed, very handsome. The Grizzly Frontignan, so liable to shank when planted in an outside border, was here in pots colouring beautifully, the bright amber colour of the berries contrasting well with the jet black of the Hamburghs. In this and the next house I noticed good plants of *Graptophyllum pictum*; *Crotons pictum*, longifolium variegatum, and variegatum; *Pothos argyrea*; *Cordyline indivisa*; *Draena terminalis*, and a host of other variegated and fine-foliaged plants too numerous to mention. Of the golden-veined *Lonicera aureo-reticulata*, Mr. Clarke possessed a good stock, and should this stand our climate in summer only, it will make a very effective edging. Who will be the first to try it? Mr. Clarke intends doing so this summer, and I hope he will communicate the result.

In the centre of the gardens stands a large greenhouse, or rather vinery, used as a late house. The Vines were just setting and promised an abundant crop. Under the Vines on a high steep stage were a great many winter-flowering plants, as *Cytisuses*, *Camellias*, *Azaleas*, &c., making good wood, the Azaleas being neatly trained. The house is heated by a combination of smoke-flues and hot water, just reminding one how ineffectual flues are in large houses.

Probing Mr. Clarke on the subject of flues *versus* hot-water, his reply was in favour of flues for small houses and a series of houses wide apart; but in favour of hot water for large houses or a series or range of houses requiring a forcing temperature. Notwithstanding that the houses at Studley are wide apart, most of them are heated by hot water and the old flues done away with, for all the houses are very old. Most of them, however, are kept at a high temperature.

Close by here are the under-gardeners' rooms, not so bothy-like as some of the like kind in other places, nor half so inconvenient. A commodious fruit-room, or rooms, potting-sheds, &c., adjoin. Another walled compartment, called the orchard, contains all the best kinds of hardy fruit trees in full bearing; and on the north wall (south aspect), were some very fine Apricot trees, Moorpark chiefly, loaded with fruit. How many Apricot-houses have 700 fruit in them? Yorkshire is "a county where Green Gage Plums are never seen in perfection," says the writer of a book reaching into tens of editions; but so far is this from being true, that not only Green Gage Plum trees in Yorkshire bear well as standards and yield bushels of fruit, but there are Apricots on many cottages the fruit of which annually pays their rent.

In a Cucumber-house heated by hot water, the old flues being done, we saw Reynolds's Winter Cucumber. It is a free bearer; but as for being a handsome fruit, it is just the contrary. Nevertheless, it is said to be good for use, and it hangs a long time. Adjoining is a Pine-pit with plants in a flourishing condition, and some young Vines preparing for forcing, amongst which were Chavoush, Denbies Muscat, and other select and new kinds. In a small compartment were *Alocasia uetallia*, *A. macrorrhiza variegata*, and other choice plants.

In the way is another Cucumber-house planted with Carter's Champion (will any one tell me the difference between Champion and an old kind that was formerly grown under the name of Smither's Winter Cucumber, or Scott's Winter?) and on some shelves at the back were Oscar Strawberries bearing profusely in pots. This variety promises to be a good forcer.

Time would not allow of my seeing much more; but in a dung-frame I noticed an abundant crop of Melons, large enough for anything. The kinds were Orion, Golden Perfection, and a new kind, Princess Alexandra, evidently a good cropper, large, and of handsome shape, and if it be as well flavoured as it looks it will merit its name.

Crossing the park I reached the old flower gardens, and these call for a few remarks. They form one of those old-fashioned places with winding paths, verdant lawn distinguished by a bed here and another there, and shrubs planted hap-hazard. An old greenhouse with high front-lights or windows and an opaque roof shows old notions, and is, of course, of little value for plants, but it was gay with some

Geraniums, &c. A tea-house ornaments the centre of the garden, and some beds of various shapes in front, planted with bedding plants, looked pretty. On the lawn is a very large round bush of the variegated Box (*Buxus sempervirens variegata*), about 15 feet high, and not less than 60 feet in circumference. Besides a fine *Cedrus deodara* and *Picea cephalonica*, I noticed *Picea nobilis* or an intermediate variety between that and *Picea Nordmanniana* about 25 feet high. Roses in flower, *Rhododendrons*, ornamental deciduous trees, and evergreen shrubs worthy of note, are also met with everywhere.

Somehow I have omitted mentioning a Peach-house in its proper place; and as I noticed not only some fine fruit on the trees planted out, but some trees in pots preparing for forcing, I took Mr. Clarke's opinion about trees in pots. For early forcing or affording a few fruits early he considered a dozen or two of great service, but for affording a supply he denied their utility.

With another look at the new flower garden, and thanking Mr. Clarke for his kindness, I departed. In conclusion let me add that every thing under Mr. Clarke's management denoted indomitable perseverance, intelligence, and skill. In the welfare of his assistants he also takes great interest. They are privileged to leave work at five o'clock on Saturdays; and I trust that ere long every gardener and every man employed in gardens will have his hours of labour shortened, not only at Studley, but throughout the country, and instead of leaving work at five o'clock on Saturday, that they may have Saturday afternoon, like other trades, to themselves, to improve themselves by visiting other gardens, and collecting plants or studying nature in the field. Men who would not work harder during the remainder of the week to make up for Saturday afternoons I would discard from the gardening world; but I feel sure they would, and that no employer would regret granting the advantage.—G. A.

ROOTING STRAWBERRY-RUNNERS.

In rooting Strawberry-runners into small pots, ought the pots to be put under the first joint of the runner (I mean the joint nearest the plant) when the roots are sprouting, or under the last bud? If put under the first joint, ought the end of the runner to be cut off?—M. B.

[The question is of more importance than would appear at first sight. When it is desirable to increase a favourite kind every runner made may be layered with propriety, and thus a great number of plants may be obtained from one stool. In this case the first layer is put in, and every one that comes after in succession, and none are cut from the mother plant until all are rooted. In such case the first layers will generally be the strongest, and we would advise their being kept by themselves and planted by themselves. Where time and means exist, this plan of rooting the young plants is by far the best for making autumn-plantations, as the plants will be strong and established enough to produce a fair crop of very fine fruit the following summer.

We lately stated that we approved of layering the plants in small pots when forcing plants were required; but we said nothing as respects our correspondent's interesting inquiry as to what would be the best layer to adopt. Here, then, we must just tell what has been our practice of late, though somewhat opposed to the theory which experiments led us to consider as the soundest and best in the matter, if circumstances admitted of its being carried out.

To clear our way we must here allude to another query about runners, sent by a correspondent "Quiz," who has had a hot discussion with a friend as to whether runners were to be looked upon as feeders or robbers. We think that both are right and both are wrong, according to the stand-point of the argument. For instance: here is a Strawberry-stool that we wish to become as bulky and luxuriant as possible; and in such a case, were size and luxuriance the objects, we would look upon a number of runners, each rooting and catering not only for itself, but also by the connecting link for the old parent plant, as being much less robbers than feeders. It so happens, however, that we value the Strawberry-stool less for its mere luxuriance and large leaves than for its well-ripened buds and consequent extreme fruitfulness. In such a case we think little

of the young plants either as feeders or robbers. Our object is to concentrate as much strength in every parent stool as shall be compatible with the extreme of fruitfulness, and hence we shorten and remove all runners early. We even remove some of the weaker buds or shoots of the stool, not only that the strength may be concentrated, but that the sun and air may play freely round, and thus thoroughly ripen the buds for next season's produce. In gaining this result we prefer that the runners should grow a few weeks before they are nipped off, as sometimes when we have kept them nipped close all along, some of the extra strength being thrown into the buds, they were apt to burst or, as it is called, come blind, at the fruiting season. Though we generally keep our Strawberries about three years on the ground, we have often proved that if stools are so deprived of runners early, and the smallest shoots thinned out and rich top-dressings and manure-waterings given, the same plantation may be kept in good bearing order for many years, though no great advantage is thus gained—not enough, in our opinion, to make up for the advantages of a regular rotation of cropping.

Owing to the cold springs and dry summers our practice of late has been to layer the first runner that came, and, then, unless in a case of scarcity, to nip off the running point, to concentrate all the growing strength into the single runner. Thus, also, a few runners from a stool get more sun and air than if a greater number were layered. These first layers, in general, make as stated above, the finest and strongest plants, and if well managed afterwards, they will be found very fair for fruitfulness. If made too luxuriant, or kept growing too long in the autumn from rich surfacings and manure-waterings, the fine buds will be apt to split, and then it will be found that the extreme of luxuriance is not always attended with the extreme of fertility.

Though for the above reason of lateness of runners, we chiefly depend on the first-formed, we would under other circumstances be inclined to slip off the first-formed one without hurting the string, and wait for the second young plant on the runner to layer. Several years ago, we made experiments in this direction, and although the results were not in all cases so conspicuous as to give grounds for forming an unalterable theory, still they were such, as, on the whole, fully to convince us that the second young plant formed on the runner, though generally less luxuriant, was also generally more compact and fruitful. In this case two new runners were allowed to go beyond the layer on the pot. On account of the dryness of the ground, we have been obliged to take the first runners, and these will be none too early for early forcing; but we should be glad if others more favourably situated would make some experiments in this direction, as what may be of less moment when some thousands are grown, may be of considerable importance where only a score or two of pots can be managed.

From whatever cause, some stools will often be found much more inclined to sterility than others in the plantation, and these should be either pulled up or marked, so that no runners be taken from them. This is the more necessary, as almost constantly such plants send out the earliest and strongest runners, and the sterile habit is almost sure to be continued. We recollect picking-out such stools of the Elton perfectly barren, when all around them had a dense crop, and on marking and trying layers from such plants for four years, we never gathered a fruit from them. A little trouble in selection, therefore, is far from being labour lost in small gardens, where every foot of ground is an object. Take layers, then, if possible, from the best bearing plants.—R. F.]

FRUITERS' COMPANY.—On the 8th instant, the Master of the Fruiterers' Company (William Brown, Esq.), with the Wardens (Josiah Walker, Esq., and Hilary Nicholas Nissen, Esq.), and Mr. O. C. T. Eagleton, the Clerk of the Company, waited upon the Lord Mayor at the Mansion House by appointment, and presented his lordship with a choice selection of all the fruits of the season. The Master and Wardens in addressing the Lord Mayor, referred to the deviation the Company had made from the ancient custom of presenting sundry bushels of Apples in the winter, and expressed a hope that the present now made would be more acceptable. The Lord Mayor acknowledged the present in

a very pleasant and appropriate manner, while the Lady Mayoress and the ladies of her family inspected with much delight the splendid specimens of Pines, Grapes, Peaches, Nectarines, &c., which were displayed in the saloon.—(*City Press*.)

THE OLD KENTISH PLOUGH.

It is seldom that the gardener calls in the assistance of expensive machinery to aid him in his manifold duties. True a water engine is a machine; and of late years much improvement has been made in mowing machines, which, in fact, have become so common, that it is a question if more turf is not kept in trim by these appliances than by hand-mowing. Machines for fumigating and dusting plants with sulphur have been tried, but are often more novel than useful; and there seems much difference of opinion about the relative values of the different tree-planting machines. The one containing the greatest complication of parts, giving it the greatest claim to the character of a machine, is certainly not the best; it is, in fact, more a mechanical apparatus than a horticultural one.

Pre-existing machines of a simpler construction, which did their work with a less amount of screw and other complications of a mechanical kind, but with, perhaps, an increased amount of hand-labour, did it much better for the patient operated on; simplicity in most things is best for the multitude, and unless a piece of mechanism perform its work much better and cheaper than the same can be done by hand it soon falls into disuse. Its strongest advocates fail in maintaining its popularity, and the original implement it was intended to supersede is restored to favour again. Nevertheless, we now and then meet with decided improvements in something where it was thought perfection already existed. Tools have been much improved in the last few years, digging tools especially; and the implements used in different localities have been brought into competition with each other, and the advantages and disadvantages of each made apparent to all not too deeply tinctured with prejudice.

Every one connected with rural affairs knows a plough; but there are plenty of ploughmen who are, no doubt, adepts at their calling that would be puzzled to understand the action of a Kentish plough; and if they accidentally came upon one not at work, they would, in all probability, suppose it to be intended for some other purpose than tilling the soil. And yet this implement—heavy, cumbersome, and to all appearance the most antiquated in its class—has not been exceeded in the quality of its work by the best-constructed implement that has been brought to contend against it from the manufactories which have a European reputation for the skilful adjustment of all the parts of their implements. In the matter of ploughs, Kentish farmers have taught their brethren a lesson in other parts of the kingdom, while in return they have received some useful hints in the same way themselves. Doubtless some amount of prejudice still exists in both cases, but that will in time vanish. Sound principle will in the end prevail; and when once the way is opened for the admission of an error, its removal is more easy. Returning, however, to the matter of ploughs, let us see in what way the Kentish plough differs from others in the way in which it does its work.

In most parts of England where I have been the ploughing-up of a Clover-bed is regarded as a job in which ploughmen delight to show off their skill; and when working hours are over it is not unusual to see them all walking backward and forward along the headland, examining with the eyes of connoisseurs each other's work, and commenting accordingly. The qualification for such work is to exhibit the furrow slice turned up with great exactness, so as to resemble the ridge of a house, or, in fact, a series of ridges and furrows, each side of the ridge presenting the angle of 45° ; and, assuming the sharp edge of the ridge and of every ridge to be straight, the work would be considered well done. This is, or until lately was, one of the criterions of good ploughing in the central and northern counties of England. We will now compare it with what is done in Kent.

The Kentish ploughman turns over his furrow in quite a

different manner. He has been to see the fashion of ploughing in the midland counties, and he tells them plainly they do not turn over the soil at all, they only turn it three-quarters over; that their vaunted angle of 45° means that instead of having turned the ground over as much as 180° , as he does at home, they have only moved it 135° from its original position; and that he could show them how to turn it upside down, which, in fact, he does completely—the criterion of good work with him being to do so, leaving the bottom of the furrow slice quite flat on the top and a clear crease or line of marking between each furrow as straight as possible. The advantages of this plan are that any weeds, rubbish, or dung that may be on the top is completely buried, the weeds being less likely to grow than when half buried in the three-quarter-turnover system of other places, and he consequently feels not a little proud of the old-fashioned wooden instrument which he sees others despise.

Kentish ploughs have also another peculiarity—only one furrow is wanted, as they are so constructed, that by the movement of a mould-board and another direction being given to the coulter when they come to the end of a furrow, they return in the same ground, and turn the soil in the reverse way, the alteration not taking more than a minute to make. Much stress has been laid on this point at meetings where Kentish ploughs have competed with others, the latter requiring two furrows to be thrown against each other to start with, forming a sort of ridge, certainly not wanted for any purpose; whereas the Kentish plough, by beginning at the outside, and using only one furrow, leaves all its work as level as where it begins. It is needless to say it could go round a piece the same as other ploughs do; but it is seldom if ever done. Some little alterations have been made in it during the last few years, but comparatively few to what its neighbour, the iron plough, has undergone in the hands of a Howard and a Ransome; and it is not too much to say that these great makers have borrowed from the Kentish plough more than that implement has done from them; and at a challenge meeting some two years ago, between the advocates of the ploughs of one of these makers and the old Kent implement, much interest was evinced, and impartial judges were unable to determine which of them did the best work. Even scientific men, who assume to be oracles in their way in deciding on the laws which ought to govern mechanics, have found their theories overthrown at times by the performances of the Kentish plough.

A gentleman well versed in engineering matters and mechanical constructions, thought he had invented a much lighter implement, but when subjected to the test of the dynamometer, it was found to be the reverse in the draught wanted. One or two leading features in the Kent plough being good seem to atone for all that appears clumsy. The parts that penetrate the ground are long, the sole of the plough being upwards of 4 feet in length, and the wing as long; and it is pulled forward like a long, thin wedge rather than a short thick one. There is less iron in it than in most ploughs. The turn-wrest or part moveable at each end is of wood, as also are the beam and most other parts; but there being no curved mould-board as in other ploughs, strangers not acquainted with its uses would hardly suppose that it was intended for ploughing, and it seldom fails to excite the derision of such as inspect it for the first time, if not at work; but when so employed, and the qualities of the work done are examined, there is generally a pause, and an inward question is asked, Can this be wrong? Conviction is very unwilling to say No, and the idea is carried home that soils must assuredly be better that are completely turned over than those which are only partly so, and the application of this problem may be carried into other quarters as well; but enough has been said for the present, and if agreeable, I will at a future time return to the subject.—J. R.

SELECT ORCHIDACEOUS PLANTS.—The fifth Part of this beautiful and trustworthy publication is just published, and is a worthy companion to its four predecessors. It contains *Pleione lagenaria*, *Vanda cœrulea*, *Dendrobium Wardianum*, and *Lælia superbiens*. The portraits by Mr. Fitch, the descriptions by Mr. Warner, and the cultural directions by Mr. Williams, are all excellent.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

RHODODENDRON BATEMANI (Mr. Bateman's Rhododendron).—*Nat. ord.*, Ericaceæ. *Linna.*, Decandria Monogynia. Discovered by Mr. Booth in the Bhotan Himalaya. Very robust. Flowers crimson and large. Noble species.—(*Bot. Magazine*, t. 5387.)

ORNITHOGALUM CAPITATUM (Capitate Ornithogalum).—*Nat. ord.*, Asphodeleæ. *Linna.*, Hexandria Monogynia. Bulbous-rooted greenhouse plant from Cape of Good Hope. The white and purple flowers open in February.—(*Ibid.*, t. 5388.)

MEYENIA VOGELIANA (Vogel's Meyenia).—*Nat. ord.*, Acanthaceæ. *Linna.*, Didynamia Angiospermia. A most lovely stove plant from Fernando Po. Flowers purple with orange throat, opening in May.—(*Ibid.*, t. 5389.)

NEPHELAPHYLLUM SCAPIGERUM (Scapigerous Nephelaphyllum).—*Nat. ord.*, Orchidaceæ. *Linna.*, Gynandria Monandria. Imported from Borneo by Messrs. Low & Sons, Clapton. "A singular and beautiful little Orchid." Flowers yellow and white with purple blotches.—(*Ibid.*, t. 5390.)

ERIA OBESA (Thick-stemmed Eria).—*Nat. ord.*, Orchidaceæ. *Linna.*, Gynandria Monandria. Native of Martaban and Moulmein. Flowers white. Flowered in a warm stove in February.—(*Ibid.*, t. 5391.)

JAPANESE CLEMATISES.—*Clematis Fortunei*, white; and *Clematis florida Standishii*, violet blue. Both plants were found by Mr. Fortune in Japan. Probably hardy, and have had first-class certificates from the Floral Committee of the Royal Horticultural Society.—(*Floral Magazine*, pl. 153.)

PEARCE'S OURISIA (*Ourisia Pearcei*).—A dwarf hardy perennial of great beauty. Introduced from Chili by Messrs. Veitch, Chelsea and Exeter Nurseries, through their collector, Mr. Pearce. Flowers crimson streaked with darker crimson. It had a first-class certificate from the Floral Committee.—(*Ibid.*, pl. 154.)

RHODODENDRON PRINCE OF WALES (Rollisson's).—A cross-bred between Rhododendrons javanicum and retusum. Flowers bright orange.—(*Ibid.*, pl. 155.)

HEEBACEOUS CALCOLARIAS.—Four varieties raised by Messrs. Dobson & Son, Isleworth.—(*Ibid.*, pl. 156.)

CAMELLIA CARLOTTA PAPUDOFF.—Introduced by Messrs. Veitch from Florence. "A first-class variety." White blotches on a ground of carmine rose.—(*Florist and Pomologist*, ii., 89.)

WINTER HAWTHORNEDEN APPLE.—Roundish-oblate, large, pale yellow, mottled red on the most sun-exposed side. "The flesh firmer, than that of the old Hawthornden, with all its qualities." First-rate culinary Apple, in use from October to March.—(*Ibid.*, 96.)

CHIEF GARDENS IN GREAT BRITAIN.

I FEEL confident that the readers of THE JOURNAL OF HORTICULTURE will feel obliged to you for giving a list of the chief gardens in Great Britain; but permit me to suggest that your correspondents on the subject should be careful in stating to you whether their lists comprise the principal or a few of the best gardens of a county, for it is very evident that the gentleman who furnished you with a list of the "principal gardens in Northumberland" has never crossed the Aln, otherwise he would not have omitted Chillingham Castle, where the finest flower garden in the county is to be seen, and where the greatest number of bedding-out plants are; and it is quite patent that there is a very superior selection of French Pears cultivated successfully in the fruit gardens; and in the American garden, quite distinct from either of the above, there is as fine a collection of Rhododendrons as is to be found in the north. Mr. Bowey is gardener. And why should he omit Lilburn Tower close by, the seat of—Collingwood, Esq., where the gardens are almost overshadowed by the cloud-capped Cheviots? Yet here in the earliest spring Nature bursts into such beauty, that I have frequently gone miles out of my way to see in bloom the splendid collection of Rhododendrons, Azaleas, Kalmias, and other spring-flowering shrubs which thrive so well under the treatment of Mr. Dees. Both fruit and flower garden are good. Here, also, about four or five years ago they could boast of an Araucaria imbricata only second to some of those fine specimens at Belsay. Mr. Dees is very

successful with the Wellingtonia gigantea, but none of them are so tall as that very fine specimen near to the old castle at Belsay.

It would be an easy matter for me to name at least seven or eight gardens in Northumberland equal to, and some superior to, those named in your Journal this week. Why are Howick Gardens not named, the seat of the Right Hon. Earl Grey, Mr. Moore, gardener? It is true there are better Orchids at Wallington and Cresswell; but Howick Gardens are of more general interest to the tourist and visitor than some you have named; so, also, are those of the Home Secretary, and Eslington Gardens, besides many others.—P.T.E.R.I.S.

[We wish that our correspondent had increased our obligation by giving a tabular list of all the gardens he knows worthy of a visit. No one can be acquainted with all such gardens in a county, and we wish every correspondent to particularise only those really known to him. We cannot have too many of such contributions, and we shall be obliged by any one sending us the names of any two or three gardens he knows are worth visiting.—Eds.]

THE GREAT BIRD QUESTION.

IN No. 117 of THE JOURNAL OF HORTICULTURE, Mr. Robson asks for evidence that small birds eat caterpillars. I can supply some on this point. A pair of the large titmouse this year made a nest in the potting-shed in the garden here, and reared a numerous family—six or seven, I believe. One day, being in the shed, I saw both the parent birds on an Apple tree within a very few feet of me, and each with a caterpillar, about three-quarters of an inch long, in its beak; whether these were the caterpillars which infest Gooseberry bushes or not I cannot pretend to say, but, like them, they were of a light colour. The destruction of caterpillars by this pair alone was, in all probability, very great, as there was so numerous a family to feed.

Since the young birds have taken to the wing they are, however, often to be seen escaping from the rows of Peas with a Pea in their beaks; and I apprehend that the same is the case with many small birds, that their parents feed them with insects while in the nest, but that when they have to provide for themselves they indulge in a mixed, or, perhaps, sometimes an entirely vegetable diet. If this be so, the proper course seems to be to leave them undisturbed while nesting, and to diminish their numbers, where necessary, at a later time.

I have no hesitation in saying that in some places very little fruit would be left if the birds were allowed to increase without check. It must be remembered that their natural enemies, hawks and owls, are actively persecuted by gamekeepers, and very greatly diminished in numbers.—SUSSEX-ENSIS, K—Park, Sussex.

MAY FLOWERS.

FLOWER gardens in most places are, during the month of May, very deficient in a fine display of bloom. The bulbs such as Crocuses drop; Hyacinths, &c., are all over; and the bedding-out plants are only just planted out, and not in bloom, even in the most favoured places as to climate and shelter. Though many of our aristocratic families are during that month in London, yet there are large numbers who have nice gardens that prefer the country—their home in fact, to the dust, heat and discomfort of town life. Such families, no doubt, would be glad to have their flower-borders well-stocked with Flora's gifts, but they are not just up to the mark how to accomplish this point in May.

The above reflections passed through my mind on visiting a garden near Manchester that I have referred to more than once, I mean the garden belonging to J. Shorrocks, Esq., the Lodge, Ashton-on-Mersey. I saw these gardens about the middle of May, and a more gorgeous display of flowers I never beheld at any time of the year at any place whether in England, Ireland, or Scotland. The garden was literally a blaze of flowers, old-fashioned indeed, but yet very gay and effective. For the most part they grew on borders in front of shrubs, and were in such masses that very little soil was visible.

I was so much pleased with the display that I took notes of their names, and thought the list would be useful to many of the readers of THE JOURNAL OF HORTICULTURE. I was somewhat surprised at the small number of species, though that only shows how a good gardener like Mr. North may furnish his employer's flower-border at, comparatively speaking, little or no expense.

In order to render this list as useful as possible I shall not only give their names but also their colours, height of growth, the soil they will thrive in, and lastly the mode of propagation.

ALYSSUM SAXATILE.—Bright yellow. Height 9 inches. Soil, light sandy loam on a dry bottom. A plant that spreads much; many of the patches have measured 3 feet across. Propagated by slips put in in June under a bell-glass; but the best way to procure a stock is to purchase a shilling packet of seed and sow in April or early in May on a warm border, and transplant the seedlings, as soon as large enough, where they are to bloom. In order to obtain a large patch quickly, plant five plants 6 inches apart together, and the second year they will make a dense mass and a good display.

ANTHERICUM LILIASTRUM.—Clear satiny white. Height, 1 foot, light sandy loam well-drained. Propagated by dividing the plants in autumn.

AUBRIETIA DELTOIDEA.—Blue. Height, 2 inches. Soil, light sandy peat and loam. Propagated either by slips put under a bell-glass in a shady place in June, or by dividing the plants just after the bloom is over, watering the divisions every evening if the weather is dry. A beautiful spreading plant.

BELLIS PERENNIS.—A dark red variety. Height, 4 to 6 inches. Soil, any good garden. Propagated by divisions after flowering. Plant five together to form a good patch to be effective.

CHEIRANTHUS MARSHALLI.—Deep orange. Height, 9 inches. Soil, common garden. Propagated by slips taken off in May, June, or July, and planted in a bed, shading and watering them till rooted. This beautiful plant is easy to propagate. I seldom lose a single cutting. To make more sure it is desirable to make each cutting with a portion of hard woody stem at the bottom. Such cuttings or slips are more certain to root. As soon as they are rooted lift them up carefully, and transplant them where they are to flower. Here again, in order to make a good show of bloom at once, these young plants should be put in in patches of at least five together. Plant one in the centre and four around it, and you will have a goodly display the year after.

IBERIS SEMPERVIRENS (Perennial Candytuft).—Height, 6 inches. Colour, clear white. Soil, any good loam not too rich, or it will spread too much and not flower freely. Propagated by cuttings in June under a bell-glass, though I strike the cuttings freely enough when planted in shallow

pans in ordinary loam and sand, with a layer of sand on the top, and placed in a shady part of a greenhouse. The best kind of cuttings are such as are a little hardened at the base. With such I generally manage to root nine cuttings out of ten. When rooted plant them out in patches of three only, because the plant naturally spreads very much. I find it necessary every year to cut the plants in severely as soon as the bloom is over, in order to keep the patches within moderate compass. This is one of the greatest ornaments to the flower-borders throughout May; with me it is just going out of bloom in the first week in June.

PANSIES.—The dark varieties are most suitable for a mixed flower-border. I observed at this place that the yellow and white colours rather predominated: hence the dark varieties of Daisies and Pansies were most to be preferred. Any common kinds answer the purpose, provided they are pretty hardy and free bloomers.

VERONICA DECUSATA.—Pale blue. Height, 1 foot. Soil, common. Propagated easily by division as soon as the bloom is over. To form a large patch, plant five or more plants together at 6 inches apart. I am not certain this is a correct specific name, especially as I cannot find it in the *Cottage Gardener's Dictionary*. It is, perhaps, *V. gentianoides*. At any rate, it is decussate, and is a handsome border perennial, perfectly hardy, and delicately beautiful.

With these few species of hardy perennials planted at regular intervals, the borders here in May were truly splendid. No doubt the collection might be more numerous, and Mr. North informed me he intended to add to it as soon as he could. I ought to mention that the effect was enhanced by a good collection of hardy Azaleas of various colours, which formed a pleasing background to the low-growing flowers. The pleasure ground was in high order, the lawn close-mown and of the finest kinds of grasses, the lines of the borders were well defined, and not a vestige of a weed was to be seen.

In the parts where bedding-out plants are used, Mr. North had ventured to plant out early, and fortunately no late frosts have taken place in the neighbourhood. So it is to be hoped that this style of flower-gardening will be more effective than it was last year, when in many places in the north, owing to the wet summer, many beds totally failed, others grew too much into leaf, and even those that did flower had their blooms dashed and spoilt by the splashing rains.

I was much pleased with a novel mode of forming a ribbon-border here. It is the gardener's invention, and looks well, even as soon as it is planted. There are two straight lines and then two wavy lines that cross each other. These two lines are planted with Flower of the Day Geranium crossed with *Calceolaria Aurea floribunda*.

I send a rough sketch of the bed or border. It is 72 feet long and 12 wide, and is planted thus:—

1. Walk in front of hothouse.
2. Edging of Box.

3. Lobelia speciosa.
4. Variegated Sweet Alyssum.
5. Grass border.

6. Purple King Verbena.
7. Firefly Scarlet Verbena.
8. Low hedge.

9. Tom Thumb Geranium.
10. *Calceolaria Aurea floribunda*.

The sketch is drawn to a scale of one-eighth of an inch to the foot. It is just half the length of the border. I have seen the latter since the above was written, and in my opinion it is much more pleasing and elegant than mere

straight stiff, lines. Next season let some one that has space try the same plan, I am sure he or they will be well pleased with it.

T. APFLEY.

ECONOMICAL ARRANGEMENT OF FORCING AND PLANT HOUSES, &c.

IN these days of rigid economy, when persons of ample means delight to deal in the cheapest market, perhaps the following plans and suggestions for the economical arrangement of plant-houses upon a small scale, may not be without interest to some of our amateur patrons; and even young gardeners and nurserymen may study them possibly with profit to themselves. The plans have been prepared not only with strict regard to economy of space—a matter of considerable importance in small gardens—but also so as to turn the whole of the materials to the greatest advantage, and that at, considering the permanence and durability of the erections, a very moderate cost. In the construction of horticultural as in all other buildings, there is no economy in “make-shifts;” the best materials and the best workmanship will ultimately be found the most economical, and those who save a few pounds by what is technically called “scamping a job,” in the first erection, will generally find that they have been penny wise and pound foolish before the end of the first seven years. A range of houses on this plan has lately been erected for a gentleman. The forcing-house has yielded abundance of Roses and other forced flowers, with splendid Cucumbers, and at the present time a very fine crop of Melons is coming forward. These and the Cucumbers are grown in large pots plunged in leaf mould over the tank, and the roots are allowed to grow in the plunging materials. Under the Melons, &c., which are trained within a foot of the glass, plants for flower garden purposes are propagated, and a few stove plants, as Gloxinias, Achimenes, Gardenias, &c., are grown underneath. For the above purposes, or for the cultivation of a select collection of stove plants or Orchids, or even for the growth of the Pine Apple, perhaps no better arrangement could be made, the command of heat, both for the plunging-bed and the atmosphere, being of the most efficient description.

If the forcing-house was devoted to the cultivation of Orchids, for which it is admirably adapted, we should build the inner walls on each side of the pathway in rockwork, and also place a mass of rockwork the whole width of the house against the end wall, leaving niches to be filled with suitable material for the cultivation of some of the finer kinds of Ferns, Mosses, and such Orchids as are likely to succeed in such a situation. By merely opening a communication on each side from the tank and heating-apparatus, the rockwork might be supplied with any amount of moisture or bottom heat; and by simply placing a cistern of water above the level of the rockwork and over the boiler, silvery streams of warm water may be made to trickle over the tortuous

track of the rockwork, finally refreshing the feelings, and ministering to the picturesque character of the scene, by terminating in a miniature waterfall, the grateful rippling of which will do much to cheat visitors into the belief that the house is not so warm as the proper cultivation of its occupants renders it necessary that it should be.

“Oh! but,” remarks some adept in the art and mystery of growing Orchids, “to do the various kinds justice, and produce them in perfection, two houses are required.” (Granted; therefore, if you please, we will confine the Indian kinds to the house we have been speaking of, and by continuing the same heating arrangements, we will convert the greenhouse into a house for the growth of those kinds which are natives of Mexico and colder climates; and thus, with

one exception, we have arrangements as complete as the most fastidious could desire, where light, heat, and moisture are at command, to do all that is required for the proper cultivation of this beautiful tribe of plants. Indeed, in the laconic language of one of the best gardeners in the country, these are “nice snug houses,” suitable for plants of all kinds; and if Nature’s journeyman, the gardener, only performs his part properly, success is certain.

For the cultivation of Vines in pots, such houses would be perfect; and one of these houses, with the side-pits to bring on successional plants, would produce Grapes sufficient for a small family, and that for several months in the year.

In the construction of this range of houses the position of the boiler is not indicated, but we propose to fix it at the north end of the forcing-house, to heat the tanks, house and pits, independently of each other, hav-

ing stop-cocks or valves to each set of pipes, so as to work the whole or a part at the same time, as may be necessary. The greenhouse will be heated by continuing the pipes from the forcing-house, placing stop-cocks where the pipes enter the greenhouse. The pipes for surface heat are placed in a trough lined with cement, so that in case of need, when a very moist heat is required, water may be placed around the lower pipe to create moisture. The pipe for surface heat must be 3 inches in diameter, and those running through the tank for bottom heat 2 inches. For the side pits two-inch pipes will be sufficient for ordinary purposes; but if a strong heat is required, why then, three or four-inch pipes will be required.

The cold pits adjoining the greenhouse will be found very useful for the growth of Mignonette, Violets, and Stocks through the winter, and also for protecting plants for the flower garden, and in the heated pits Roses and other flowers may be forced.—(A., in *Gardeners Magazine of Botany*.)

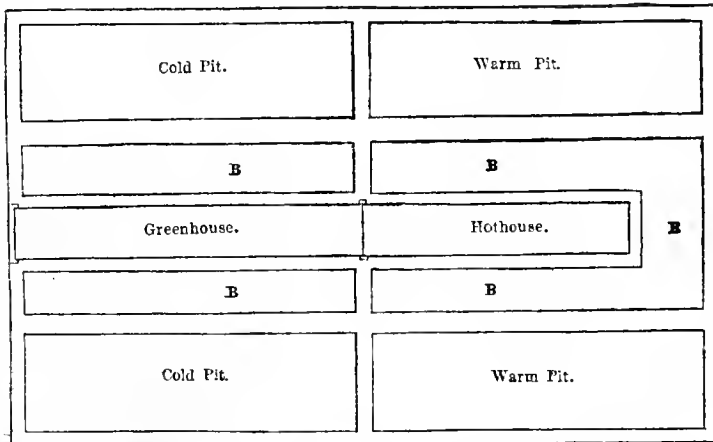

SECTION OF FORCING-HOUSE.

REFERENCE TO PLAN.

- A, Pathway.
B, Bed for plants to stand upon, or be planted in.
C, Hot-water pipes three-inch diameter in house, two-inch in pits.
D, Hot-water tank for bottom heat, heated by two two-inch pipes.

GROUND PLAN OF HOUSES AND PITS.

THE BIRMINGHAM ROSE SHOW.

JULY 16TH AND 17TH.

When any great design is carried into effect and proves to be a success, the word "patronage" is whispered about as though the rich man's purse were the only or chief motive power; but those who are in the habit of looking beneath the surface will surely acknowledge a motive power still more potent. In support of this view I would instance the late Birmingham Rose Show, which, as a Rose show, I believe was second to none in the kingdom, and, probably, in the world; and it was held in the midst of a manufacturing town which, like manufacturing towns in general, is densely populated, very smoky, and inhabited by two classes of people—employers and employed, boasting of few if any of the upper ten thousand.

The Town Hall in which the Show was held is a fine massive building of the Corinthian order of architecture. Interiorly it is both spacious and lofty, and the ceiling is finely decorated. At one end is an orchestra surmounted by one of the finest organs in the country; and below the organ a crescent was formed by some of the stages or seats being arranged with Camellias, Conifers, Ferns, and other plants, and within this crescent the band performed.

The Roses, which certainly were the principal features of the Show, were arranged on stages in the body of the building; and although a portion of them were to be found up-stairs, the most important collections were below. Each temporary stage contained two rows, and between these were Ferns, Begonias, Caladiums, &c., the whole looking exceedingly well and doing credit to those who had the arrangement of them. I took a few notes of the Show, which I send for the benefit of your readers; and though my remarks may not be in so masterly a style as those of a professional reporter, yet I will do what I can.

In giving any opinion on the condition of the flowers I can only speak from impression, for, not having seen the preceding Shows, I cannot speak from comparison. There were Roses that had not attained their best, and there were those that were past it. Some were not without fault as to form and colour; but, on the whole, I consider they were very good. Some would say that the flowers were too open, but every Rose-grower knows what a difference a single day will make in the appearance of a flower in the bright sunny weather that has lately prevailed. Making allowance for this, I consider no one has a right to complain that the exhibitors had not done well. Certainly instances were not wanting in which the same varieties would differ considerably on different stands; but this is natural and may be the effect of locality, or it may be that individual flowers differ on the same plant.

In Class A (Nurserymen), ninety-six varieties, single trusses, the first prize was awarded to Mr. B. R. Cant, Colchester. Among his lot were *Lelia* (very fine), *President*, *Madame Vidot*, *François Lacharme*, and *Gloire de Dijon*, all first-rate. The second prize went to Mr. John Keynes, of Salisbury. In this collection were some good blooms of *Jean d'Arc*, *Jules Margottin*, *Maréchal Vaillant*, *Mlle. Bonnaire*, *Comtesse Oubaroff*, *Madame Knorr*, *Beauty of Waltham*, *Alphonse Karr*, *Celine Forestier*, *Lady Stuart*, *Madame Hector Jacquin*, *Madame Boll*, *Triomphe de Rennes*, *Gloire de Santenay*, *Olivier Delhomme*, *Souvenir de Comte Cavour*, *Baron Gonella*, *Comte de Nanteuil*, *Général Jacqueminot*, *Gloire de Vitry*, *Senateur Vaisse*, all good and fresh-looking—more so, in my opinion, than the preceding, and they were certainly better arranged. Messrs. Paul and Son, Cheshunt, and Mr. W. Paul, of Waltham Cross, were equal third in this class. In the collection of the former were good flowers of *Eugène Desgaches*, *Comtesse Cécile de Chabillant*, *Duc de Rohan*, *Jaune de Smith*, *Madame Pierson*, *Niphotos*, &c., all good and neatly packed; but many would say the flowers were too full blown. Mr. W. Paul's collection contained, in addition to fine flowers of some of the above, *Duc de Cazes* (very dark), *Général Jacqueminot* in fine condition, and *Louis XIV.*

In this class entries were also made by Messrs. Francis, of Hertford, who showed *Louis Peyronney* very large, and the following first-rate:—*Baron Gonella*, *Louise Magnan*, *Prince Camille de Rohan*. From Mr. Turner, of Slough, whose collection looked really charming, there came amongst

others good blooms of *Triomphe de Caen*, *La Boule d'Or*, *Eugène Appert*, *Gloire de Santenay*, *Souvenir d'un Ami* (good), *Madame Bravy*, *Madame Charles Wood* (very large). Mr. Cranston's collection included many good flowers, but they were loosely arranged compared to the last. Mr. R. Smith also entered in this class.

In Class A (Nurserymen), forty-eight varieties, three trusses, the first prize was carried off by Mr. John Keynes, of Salisbury, with a most excellent stand, all fresh and beautiful. The second prize went to Messrs. Paul & Sons, Cheshunt; and the third to Mr. B. R. Cant, of Colchester. In this class were several other exhibitors, including Messrs. Francis, Keynes, W. Paul, Paul & Sons, Smith, and Turner. In Mr. Francis's collection I particularly noticed fine blooms of *Anna de Diesbach*, *Mrs. Rivers*, *Catherine Guillot*, *Comtesse de Chabillant*, *Prince Imperial*, *Madame Schmidt*, and what seemed to me *Jules Margottin* named *Senateur Vaisse*.

In Class A (Nurserymen), twenty-four varieties, three trusses, the first prize was taken by Mr. Keynes; the second by Mr. W. Draycott, Humberstone, near Leicester; and the third by Mr. George Batley, of Rugby.

Class A, No. 4, twenty-four varieties, single trusses, was open only to nurserymen in the counties of Warwick, Worcester, and Staffordshire. The first prize was awarded to Messrs. S. Perkins & Sons, Coventry; the second to Mr. W. H. Treen, of Rugby; and the third to Mr. George Batley. The other competitors in this division were Mr. J. Cole, of Birchfield, near Birmingham; Mr. R. Smith, Worcester; Mr. A. Wood, Worcester; and Mr. R. H. Vertegans, Chad Valley, Edgbaston. The trusses shown here were in no way inferior to the others, proving that these counties are well adapted for the culture of this the queen of flowers.

In Class B, No. 5 (Amateurs), forty-eight varieties, single truss, the first-prize cup was given to Mr. J. T. Hedge, Reed Hall, Colchester. Here were splendid flowers of *Reine Victoria*, *Comtesse Cécile de Chabillant*, *Beauty of Waltham*, *Jaune de Smith*, *Alexandre Fontaine*, *Madame Charles Wood*, *Louise Magnan*, *La Boule d'Or*, *Mrs. Rivers*, *Auguste Mié*, *Triomphe de Caen*, *Louis XIV.*, and *Sollaterre*. The second prize was awarded to Mr. S. Evans, gardener to C. Newdegate, Esq., M.P., Nuneaton, Warwickshire, who also had some good blooms; and the third prize to the Rev. S. Reynolds Hole, Canneton Manor, Newark.

Class B, No. 6 (Amateurs), twenty-four varieties, single trusses.—The first prize went to Mr. J. T. Hedge, Colchester; the second to Mr. S. Evans, gardener to C. N. Newdegate, Esq., M.P.; and the third to Mr. E. Sage, gardener to Earl Howe, Atherstone. These collections were all good, and some were really first-rate.

Class B, No. 7 (Amateurs), eighteen varieties, single trusses.—The first prize was awarded to Mr. C. J. Perry, Castle Bromwich; the second to Mr. J. T. Hedge; and the third to Mr. E. Hunt, whose collection included good blooms of *Smith's Noisette* and *Prairie de Terre Noire*.

Class B, No. 8 (Amateurs), twelve varieties, single trusses.—The first prize was taken by Mr. J. Stratton, Manningford, Wiltshire, with a collection including *Cloth of Gold*, *Triomphe de Rennes*, and others little if anything inferior. Mr. E. Sage, gardener to Earl Howe, had the second prize; and the third went to Mr. E. Hunt, Leicester, who had *Celine Forestier*, *Madame Hector Jacquin*, and *Madame C. Crapelet*, very good.

Class B, No. 9 (Amateurs), twelve varieties, single truss, open only to amateurs resident within fifteen miles of Stevenson's Place, Birmingham.—The first prize was awarded to Mr. W. Brown, gardener to Mrs. Alston, Elmden Hall, near Birmingham; and equal second prizes were given to the Rev. P. M. Smythe, the Rectory, Solihull, and Mr. C. J. Perry, Castle Bromwich.

Class B, No. 10 (Amateurs), six varieties, single truss, open only to amateurs resident within fifteen miles of Stevenson's Place, Birmingham.—The first prize was taken by Mr. C. J. Perry, Castle Bromwich; the second prize by Mr. W. Brown, gardener to Mrs. Alston, Elmden Hall; and equal thirds by Mr. R. Garnet, Sutton Coldfield, and Mr. B. Wright, the Quarry House, Great Barr, Staffordshire.

Class B, No. 11 (Amateurs).—Six varieties, open only to amateurs resident within three miles of Stevenson's Place, Birmingham. In this class there were no entries.

Class C, No. 12 (Open).—Collections not exceeding twenty-

four new Roses of 1860-61-62, single trusses. The first prize went to Mr. John Keynes; the second prize to Messrs. Paul & Son, Cheshunt, Herts; and the third to Mr. C. Turner, Slough. Entries were also made by Messrs. Cant, Cranston, S. Evans, and W. Paul. The collections were very similar to those in other classes, and contained many of the same varieties.

Class C, No. 13 (Open).—Best new Roses of 1860-61-62, six trusses. Here Mr. J. Keynes was first with *Maréchal Vaillant*, *Madame Furtado*, *Charles Lefebvre*, and *Olivier Delhomme*. Mr. Wm. Paul was second. He had *Madame Furtado* and *Beauty of Waltham*. Messrs. Paul & Son were third with *Madame Charles Wood*. Mr. Cranston, also, had fine trusses of *Louis XIV.*; Mr. Cant, *Madame Furtado*; and Mr. Francis, *General Washington*.

Class C, No. 14 (Open).—Best six varieties of Roses, single trusses, with stem and foliage as cut from the tree; each truss to be shown singly in a vase. The first prize was awarded to Mr. E. P. Francis, Hertford; the second to Mr. G. Batley, Rugby; and the third prize to Mr. Turner. There were many other exhibitors in this class.

Class C, No. 15 (Open).—Best design, basket or vase, of Roses and Rose foliage. Mr. R. H. Vertegans, Edgbaston, took the first prize; second, Mr. R. T. Evans, Severn Lodge, Shrewsbury; and third, Mr. Turner, Slough. There were here some fine masses of bloom, and all deserved notice; but I did not consider there was anything striking in the vases or the arrangement.

Class C, No. 16 (Open).—Best bouquet for the hand made entirely of Roses and Rose foliage. First prize, Mr. J. Cole, Birchfield; second, Messrs. F. & A. Dickson, Upton, Chester; third, Mr. Vertegans, Edgbaston.

Mr. Perry, of Castle Bromwich, exhibited a fine stand of *Verbenas*, consisting of forty-eight bunches of five trusses each. Many plants were also contributed by the surrounding gentry. There were several good plants of *Cissus discolor*; a fine *Maranta zebrina*; some very good *Ferns*, including a large *Acrostichum alciornae*, *Pteris argyræa*, and others; *Adiantum affine*, *brasilense*, and the ever-beautiful *cuneatum*. There were also varieties of *Caladiums* and *Begonias*, *Coleus Verschaffelti*, and the older *Blumei*, looking rather pale, and a few *Heaths*, at sight of which many of our good growers would make an involuntary grimace. These and other plants were contributed for the purpose of decoration and not for competition. They certainly did their part well, affording an agreeable change from the glowing masses of colour presented by the *Roses*.

Under the head of Horticultural Implements and Garden Ornaments there were many objects exhibited of considerable interest to the gardener. Messrs. Lloyd & Summerfield, Park Glass Works, Birmingham, showed an aquarium with fountain. This was surrounded with *Ferns* and fronted by a plant of *Cyperus alternifolius variegatus*, a most interesting plant. From the same firm also came vases for flowers and fruit, some of them filled as if ready for the table, and looking very tempting. A somewhat similar exhibition was made by Mr. Jackson, of Birmingham. There were also some vases and table ornaments from Messrs. Naylor and Dunn, of London. The silver plate of Messrs. Derry and Jones, Birmingham, comprised some very graceful dinner-table ornaments; also those by Mr. Spurrier and by Messrs. Gouch & Sylvester, whose flower-vases were exceedingly pretty.

Pottery from Mr. J. Jackson, glass of Mr. C. Bryan, and meteorological instruments from Mr. T. Rabone and Messrs. Field & Son, varied the character of the Exhibition as well as added to its interest.

Garden implements were shown by Messrs. Mapplebeck and Lowe; and, in looking over them, I found many really useful and well-made instruments, and some also made more for show than use. Mr. R. Thomas and Messrs. Parkes and Co. had also exhibitions of a similar character. Messrs. Mapplebeck and Lowe were also exhibitors in garden seats and ornaments, and wirework. A large wire rosery, exhibited by Messrs. G. Baker & Co., stood in the centre, being neatly decorated with plants for the occasion. Messrs. Gilbert Brothers had some very good garden cutlery. Messrs. Bentley & Stone, and also Messrs. Griffiths & Browlett, exhibited the *hydropuit*, which I found easy enough to work, especially that exhibited by Messrs. Pumphrey, which, I

think, is as good for conservatory work, and may be bought at a lower price. A number of wire garden-stands, filled with plants, were exhibited by Messrs. Mapplebeck and Lowe.

Artificial flowers were there too, showing great skill and delicacy of touch on the part of those who fabricated them. A beautiful case was shown by Mrs. E. F. Howe, of Birmingham; and those of Mrs. James Stoddard were perfection, being modelled out of rice paper, and all looking exceedingly natural. There was also a case of fruit modelled from some that were shown last autumn. They were of immense size, and exact imitations of the natural fruit. Both artificial fruit and flowers were exceedingly well done, and reflected great credit on those who made them.

To do justice to such an Exhibition as that held at Birmingham a thorough inspection must be made, and it is well worth the time.—F. CHITTY.

APHIDES AND TWO OF THEIR ENEMIES THIS SEASON.

HAVING noticed in the public papers of last week an unfavourable account from the Hop-growers in consequence of the prevalence of the aphid or green fly, I beg to offer the following brief remarks for their encouragement especially, as well as of horticulturists and agriculturists in general:—

Up to the present time, in this locality at least, the aphid has proved exceedingly injurious both to Gooseberry and Currant bushes, and, indeed, to trees and shrubs generally; but it is gratifying to be able to state that the larvæ of our old friend the lady-bird (*Coccinella*) and the larvæ of the hovering fly (species of the *Scæva* genus)—and especially the latter—are busily engaged in devouring all the various species of aphid; and I have no doubt, in a week or two, they will make such a clearance of these pests that there will afterwards be little or no cause of complaint.

These little friends of ours, but enemies to the aphid, have made their appearance much later than usual this season, in consequence, no doubt, of the cold spring we have had.

For the information of those who may not be aware of the utility and importance of these little fellows, I will give a brief description of one of them.

The lady-bird is generally well known. Its larvæ will rarely be noticed except by close observers, for it is in that state generally amongst its prey, exceedingly ugly, rough, and of a dark brown colour. The perfect insect feeds very little in comparison to the larvæ.

The hovering fly, or perfect insect of the *Scæva* genus, is two-winged, the most usual species being a little larger than the common house fly, thicker, and with longer wings and body. They are distinctly marked round the body with stripes of black and buff. They are mostly seen in fine warm weather steadily hovering amongst plants, then darting right and left. There are several species, some very small, but they are all valuable. The larvæ of those mostly seen are something like leeches in miniature, very soft and flat, of a buff colour slightly variegated, and about the size of the maggot of the flesh fly. After feeding, the chrysalis is generally formed amongst the leaves and plants on which the insect feeds.—JOSHUA MAJOR, *Knosthorpe, near Leeds*.

ON COTTAGE GARDENS.

THE advantages of the allotment system, or division of land into gardens of the size required by cottagers, are now so generally recognised, that it is scarcely necessary to advocate its adoption. While, however, nearly all are agreed respecting the benefits the system confers on the poorer classes of the community, its influence for good on the more affluent has, I think, been in a great measure overlooked. The farmers, for instance, who at one time were much opposed to its introduction in our country parishes, on the supposition that the possession of gardens would render the labourer too independent of his employer, have, for the most part, discovered that the independence it has created is of a kind with which they are not disposed to find fault—independence from relief obtained through the poor-rates. We have not indeed quite gone back to those happy times—if

ever they existed elsewhere than in the realms of poetry—when “every rood of ground maintained its man;” but, if cottage gardens continue to multiply throughout the land, we shall soon reach a state of things where every rood of ground maintaining its pig will contribute greatly to the maintenance of the pig’s owner and family.

But if the distribution of small portions of land among the labouring classes of agricultural districts proves a benefit to the large land-owners and the farmers, it is especially beneficial to one individual in every parish, whose influence for good over those among whom he is placed it is most desirable to extend—I mean the incumbent or the minister appointed as his substitute. The experience of the writer of this article may perhaps be admitted as an illustration of the fact.

About eleven years ago it was his lot to be appointed to the incumbency of a somewhat populous parish, situated in one of the most agricultural districts of the midland counties. There are now, he most sincerely trusts, few parishes in England in so neglected a state as that in which he found the village of —. There was no trace of any previous incumbent having resided there; and, indeed, it had no house for him to reside in. The land was almost entirely in the hands of large absentee proprietors; Dissent almost universally prevailed; and the place was notorious throughout the country for dissipation and deeds of violence.

To be instrumental in effecting a change in the moral aspect of the place was, of course, the earnest wish and endeavour of the writer; and though, even at the present time, he is painfully conscious that much still remains to be done, he thankfully acknowledges that a large amount of good has been effected, and for this good he is in a great measure indebted to the allotment system. It will perhaps conduce to clearness if, in detailing the means by which that system was carried out, and the general mode of its operations, he should now speak in the first person.

The most important thing to be done was naturally to build a parsonage, and thus to secure, both for the present time and the future, the residence of a clergyman in the parish; the second was to devise some plans for the gradual improvement of the parishioners. I have said that nearly all the land was in the hands of proprietors who lived at a distance from the source of their income, and who contributed in nothing to the welfare of their numerous tenantry. Among these absentees had hitherto been the former incumbents, who, as the tithes were commuted for land, were, for the period of their incumbency, land-owners of some importance. The probably permanent residence of this land-owner was now at all events secured; and it appeared to me that the possession of land might be turned to good account for the purpose of assisting in the amelioration of the position of the working classes. Land, even to the extent of a rood, or a quarter of an acre, was scarce among these, and in so great demand, that as much as £1 yearly rent was gladly given for so small a quantity, the rates and other taxes upon it being paid by the tenant. A suggestion which, shortly after entering the parish, I one day threw out to a labourer—that if a field was divided into cottage gardens, it might prove beneficial to himself and those in a similar situation—was soon repeated; and the news of the possibility of such an occurrence spread rapidly over the village, affording for the time a subject for gossip of a less hurtful kind than that which is too often the established means of entertainment in small communities. Two or three days after I received a petition signed by nearly all the labourers and working men of the place, which as it may prove a curiosity to some of my readers, I literally transcribe:—

“To the Rev. ——— Vicker.

“1852.

“We the undersigned poor of this parish do Earnestly Request your favour to allot a portion of Land to each of us The undersigned which we shall esteem it a great favour by so Doing at any Reasonable Rent you think will do us any Good By so doing we shall remain your obedient Servants.”

[Here follow the signatures of forty-nine labourers and artisans.]

The day after a supplement to this petition was sent me, with some ten or twenty more names appended to it.

However ungrammatical this composition might be, its

brief and simple earnestness spoke eloquently to my feelings, and a favourable reply could alone be given by one who was a well-wisher to the petitioners. There was a field, or close, as it is locally denominated, containing somewhat more than twelve acres of excellent land, conveniently situated for the purpose required, and forming part of the glebe. This field I divided into forty-seven allotments: which were distributed by the drawing of lots among those whom I considered the most deserving and the most in want, of those who had signed the petition. My object in having recourse to the method of drawing lots for the distribution of the gardens was to prevent any discontent which might arise from some portions of the field being deemed better than others. The price of each allotment was fixed at 12s. 6d.—the landlord paying all rates and taxes due upon it, and the tenants keeping the hedges and ditches in a proper state of repair. A few short and simple rules were printed and given to each tenant. I do not transcribe the rules, as they are, for the most part, the same as those laid down in similar instances. One deviation, however, from that similarity may be mentioned: no condition is made that holders of gardens should be regular church-attendants—my motive in omitting that usual condition being that, as many of them had been brought up in the principles of dissent from the Church, I did not wish it to be supposed that a premium was held out to them for the performance of a duty, which by other and better means I hoped in time to make them fulfil. Experience has not caused me to regret the absence of such a regulation. Indeed, on the subject of rules in general in connexion with allotments, I would remark that it is my belief, that the less stringent and the less numerous they are, the more efficient as well as the more acceptable they will be found. For their own sakes the tenants will nearly always cultivate the gardens in a proper manner; and, after all, good crops are the best tests of good cultivation.

It may farther be stated that the allotments are at the present time occupied by thirty-four agricultural labourers, four shoemakers, two blacksmiths, two carpenters, two bricklayers, two machinists (workers of steam threshing-machines), and one small shopkeeper.

The result of ten years’ experience of the working of the system may now briefly be detailed. I shall begin by observing that though the payment of rent is required but once a year—about three or four weeks after harvest (September 25th), a time when nearly all the crops have been removed from the field—I have almost invariably received the whole rent on the day appointed, and in no case have I ever lost any portion of it. I have, indeed, frequently encouraged the deserving and assisted those in need by returning to them a small part of the payment; in one case only have I remitted the whole, and that was one of great necessity; but every remission of rent has been granted of my own accord and without any solicitation from the tenants. Last year, with these deductions, the receipts for the forty-seven gardens were £27 14s. 6d., instead of £29 7s. 6d., the full amount. In the year 1857, a year in which there had been some distress among the agricultural labourers, it was £26 7s. 6d., the smallest annual payment since the establishment of these gardens. But it must be added that the rent previously paid by the farmer who had occupied the field before its division into cottage gardens, was only £15; or, taking into consideration that he paid the rates and taxes upon it, about £17.

The cultivation of the garden has, on the whole, been very satisfactory; it may even safely be asserted that the produce of the field is more than double what it was when it formed part of a somewhat large farm. The profit made upon each garden varies of course with the degree of cultivation, and is in every case difficult of estimation; but that a fair profit is made is evident from the circumstance that only two gardens have as yet been voluntarily given up, while there are ten or twelve applicants for the first vacancy which may occur.

The best result of the system has apparently been the habits of economy which it has tended to create. Money, which too often before found its way to the ale-house, is now expended in the purchase of a pig or in seed and manure—more manure being generally required for each garden than can be produced in the pigsty. I may here

mention one curious consequence of the cottagers in this village having nearly all a garden—a consequence which certainly was not anticipated when the allotment-scheme was introduced. Owing to the large quantity of cattle and horses kept by the farmers, hundreds of cartloads of farm-yard manure are carted-out along the highways during the winter season. Traces of the passage of the carts used to be disagreeably manifest to the wayfayer, and much that might have contributed to the fertilisation of the soil was converted into a public nuisance. At present the value of the fertiliser is too well appreciated for even a few shovelfuls to be left upon the road; a pleasing sight may almost daily be witnessed of small children, with their minute spades and wheelbarrows, gathering up the hitherto-wasted fragments for the increase of the muck-heaps in their gardens. Indeed, a more efficient band of little scavengers than that which the allotment-system has called into existence could not easily be found.

Enough has perhaps been said to show that in the parish of —, at least, garden allotments have proved a powerful auxiliary in ameliorating the condition of the agricultural poor; and the temporal improvement of that class of the community is intimately connected with their spiritual advancement. Indeed, whatever tends to raise the condition of the poor, places them in a favourable position to be influenced by the teaching and example of those whom Providence has placed in a superior station of life, and who desire to make use of the advantages that station gives them, to further the well-being, both temporal and spiritual, of their fellow-creatures in the lower grades of society. The poor man must be persuaded that the rich man is a friend, before he will listen to him as a counsellor.

For the purpose of showing that others have derived the same benefit as myself from the allotment system, I quote the words of a writer who has evidently had much experience on the subject, and who has published the results of that experience in an interesting little work, to which I would refer those who desire further information respecting it. It is entitled "Sketches of Country Life and Country Manners, by one of the Old School: London: Rivingtons: 1840." "Should the labourer," he writes, "unfortunately be unable to obtain any employment from the farmer, he will, at all events, have sufficient in the produce of his little plot of ground to keep himself and family from absolute destitution, without applying to the parish for assistance until a new demand for his services occurs. And, should a more favourable state of things take place, and the labourer be fully occupied with work during the whole year, the little gains of his allotment will provide him with a few comforts, or become a little store to which he may look in a season of distress or sickness." While cordially approving of these and many other remarks in the work from which I have borrowed these words, I would not be understood as coinciding with the author in all his opinions on the subject of country life and country manners.

Let me also refer my readers to another short treatise, published likewise by Rivingtons, under the following title—"Some account of a system of Garden Labour, acted upon in the parish of Springfield, Essex; by the Rev. Arthur Pearson, Rector of Springfield." The reader will there find an estimate of the nett value or clear gains to the cultivator of one-eighth of an acre; this the author puts down at £1 13s. 2d., or £2 16s. 4d. for a rood. Such an estimate, however, I consider to be higher than the average clear gains in this part of the country, where—as it is one of the most favoured agricultural districts in England—the labourer, it is probable, is more constantly employed than in most others, and has less time to spend upon his own garden. The clear profit here, I have said, it is difficult exactly to estimate; but I believe that it may be fairly stated as not under 35s. or £2 the rood.

From an article in the *Quarterly Review* (vol lxxiii., p. 477), we borrow the following statement, written in the year 1844. "Of all immediate remedies for pauperism, the allotment system offers the most cheering prospects; the experience of almost every one who has travelled in Great Britain will have afforded examples of the benefit resulting wherever land is appropriated to garden culture by the labourer in such small proportions as interfere not with his ordinary duties as a servant to the farmer.

I have now briefly given the result of my personal experience of the advantages arising from the mode, which is yearly becoming more prevalent in England, of distributing to the poorer classes of the community small portions of land at a reasonable rent, and under regulations neither too numerous nor stringent, and have endeavoured to corroborate my testimony of its utility by the evidence of others, who have had a similar experience with myself. My motive in doing so has been chiefly to gratify a wish, often indulged in, to throw into the balance of public opinion the weight, trifling though it be, of a country clergyman's practical appreciation of the good resulting from the measures I have endeavoured to describe. I would, in conclusion, most earnestly urge its adoption on all land-owners, and even on large tenant-farmers, who might, for such a purpose, doubtless readily obtain the sanction of their landlords. But most especially would I advocate a fair trial of it to the beneficed clergy in country parishes, most of whom have more or less land at their disposal. I am very far from asserting that it is the first or the most important improvement to be introduced by a new-comer in a rural district where the temporal and spiritual wants of the inhabitants have been hitherto neglected; but it is my full conviction that it will be found a most valuable auxiliary to all other means of improvement. Indeed, in one respect, it has a prominent advantage over most other modes of benefiting the poor; an advantage which the minister of the parish—who has often a great portion of his income to spend in objects of charity—will duly appreciate. It will be found as profitable to himself as it is to others; and, while obtaining a higher rent for his land, he will also, for the most part, have a more thankful and contented class of tenants than if he had let it out in larger quantities to two or three farmers. Like mercy—to use the well-known words of our great national poet—the allotment system proves itself "twice blessed," for "it blesseth him that gives, and him that takes."*—(*Macmillan's Magazine*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

ERADICATE all seed-weeds before they shed their seed; pull them up by hand, as cutting them up with the hoe, and allowing them to remain on the ground, is nearly as bad as letting them stand; for although the seed may not be ripe at the time, the sun will soon mature it. We allude particularly to Groundsel, Shepherd's Purse, and Sow Thistle. *Broccoli*, finish planting-out these and Winter Greens as speedily as ground can be obtained; for unless the autumn should prove very favourable those planted after this time will not attain much size. *Cauliflowers*, the main crop for autumn to be planted on a rich piece of ground. This vegetable, when planted at this season, becomes useful after the Peas are over. *Celery*, pay strict attention to the early crops; let them be gone over with the hand, and all the offsets taken off, and, if convenient, let them have a thorough drenching with dung water, after which, on the following day, give a slight covering of earth to prevent evaporation; it should be remembered that this plant in a state of nature is an aquatic. *Cabbages*, make a sowing of East Ham for early spring use, and the last sowing of Coleworts. *Endive*, plant it out on very rich soil. *Lettuces*, thin and transplant a sufficient quantity for use. Keep them watered during the continuance of dry weather. *Parsley*, sow immediately. If any has been left for seed let it be gathered as it ripens, or the best of it will be lost. *Peas*, earth and stick the advancing crops. *Radishes*, the Black and White Spanish to be now sown for winter use; also sow the common kinds for successional crops. *Spinach*, a good breadth to be sown. For the northern counties the Flanders should be substituted for the Round-leaved; but it is time enough for the former more south. *Strawberries*, dig down exhausted plantations, and plant the ground with Winter Greens. Use all diligence in filling-up vacant pieces of ground as they become available with Broccoli, Borecole, Brussels Sprouts, Coleworts, &c.; and where ground is scarce crops likely to come

*Much valuable information on the "Allotment System" will be found in a very well written article on the subject in the first vol. of the first supplement of the *Penny Encyclopædia*. Also in *Chambers' Edinburgh Journal*, New Series, vol iv., p. 101.

off soon should be interlined for the purpose of establishing as large a breadth of these useful vegetables as can be done.

FLOWER GARDEN.

The progress of all mass flowers to be attended to with unflinching care. In shortening-back shoots that incline to extend beyond the edges of the beds, avoid the least appearance of formality by thinning-out the under shoots, and keeping all parts of the beds of equal depth or thickness. Climbers on walls to be attended to as they advance in growth, keeping the young shoots neatly tied-in, &c. The climbing Roses will also require to be gone over occasionally for the purpose of cutting off decayed blooms. Phloxes and other herbaceous plants to be neatly tied up, avoiding huddling the shoots together as is too frequently done to save time. Any of the Perpetual-blooming Roses that have flowered very freely to be assisted by liberal waterings with manure water from the stable or farmyard tank. Indeed, too much of this can hardly be given to any of the autumn-blooming varieties. Dahlias will require abundance of water. Disbud and thin-out as the habit and constitution of the plant require it. The Pink-pipings put in early as advised, will now be ready for transplanting, and if so, let it be done at once, as they will require time to establish themselves so as to prevent frosts from injuring them. If the situation ultimately intended for them is vacant, they may be planted there at once; but if occupied at present by something else, let the young Pinks be planted 4 inches apart on reserved beds in an open situation, the soil to consist chiefly of light loam and well-rotted dung, to which may be added some charcoal dust, or charred refuse. Finish the laying of Carnations, Cloves, Mule Pinks, &c., of which there is rarely an overstock.

FRUIT GARDEN.

A systematic application of the principles of pruning should be continued to fruit trees during the summer and autumn months. The tendency to excessive luxuriance renders the operations of disbudding, stopping, and shortening shoots more particularly essential. In the first place it is advisable to pinch-off all young shoots not necessary for the framework of the tree; secondly, to stop those shoots which threaten to overgrow their neighbours; and, finally, having commenced a system of repression, to continue it with the lateral shoots which are developed by this system of stopping. If root-action become too powerful, root-pruning may, in the proper season, be practised with advantage. Strawberry-runners to be looked after either for pot-culture or for plantations. In consequence of the continued dry weather wall trees will require watering, or the fruit will drop prematurely. One thorough soaking will be sufficient to prevent any further mischief at present from drought if they are afterwards mulched.

GREENHOUSE AND CONSERVATORY.

Camellias, whenever the young wood appears to be ripening, may be removed to the open air. They thrive best in the shade, and a situation shaded from the midday sun and sheltered from high winds should be secured for them. Be careful to place them on a dry bottom to prevent the possibility of worms getting into the pots. Chinese Azaleas, which are equally forward in their growth and have formed their next season's flower-buds, may likewise be turned out; but, unlike Camellias, they require full exposure to the sun and air, and should be placed in an open situation that their wood may become thoroughly matured. It will be prudent, however, to place them for a week or two in a partially shaded situation, to harden their foliage sufficiently to bear the full sun, or the sudden change from a house to bright sunshine might cause their leaves to turn brown and burn. Calceolarias and Cinerarias to be shifted as they require, and kept cool. Heaths and New Holland plants to be freely exposed, especially at night, guarding only against heavy rains. Water regularly and copiously. Shift, stop, and train as necessary. Expose succulents freely to the light. Remove Cacti which have completed their growth to a dry airy place. Cut down Pelargoniums when the wood is ripe after blooming. When cut down to be placed in a shady situation until the most forward young shoots are in a long, then to be shaken out and repotted into small

pots, using sandy loam and peat. Afterwards place in a cold frame until they begin to grow again, when they may be fully exposed to the weather until the approach of frost renders it necessary to house them for the winter.

PITS AND FRAMES.

Commence the propagation of stock for next season, to secure strong well-established plants before winter and without the necessity of keeping them so close and warm as to induce weakly and watery growth. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

As we could water very little, did what we could to prevent crops being burned up. Think we will manage for another eight days, will then be at our wits' end as to nice succulent Lettuces, Cauliflowers, and even Peas. The extreme brightness of the sun, and dryness, will also tend to break in on our contemplated succession of crops; but we must just do our best. Shaded Lettuces, Cauliflower, Celery, &c., with branches that had previously been withered. These will do something to break the force of the sun's rays. Watered some young Lettuces intended to stand where sown. Planted-out Lettuces, and cut-in the side leaves considerably before doing so. "What a Goth!" we hear some reader say; "the more leaves the quicker would the plant be established." We grant the fact, if you could protect and shade, and make an interesting patient of every Lettuce plant. The more leaves kept from flagging the sooner will a plant or cutting root and establish itself. But it is the flagging that is the drawback, and the more and larger the leaves, the greater the likelihood of flagging and dying in such weather as the present. Not only so, but all Lettuce ground where planting is resorted to must be pretty rich, and, therefore, worms and slugs may be expected; and these will either pull the flaccid leaves into their holes, or feed on them as they lay withering on the surface of the ground. We, therefore, cut off a few of the largest of the leaves before planting, so that the plant may stand up boldly, and thus be so far free from the attacks of worms and slugs, and also from the reduced surface for evaporation there will be less necessity for repeated waterings. In all such weather, however, much labour may be saved by sowing such crops thinly, thinning-out, and leaving the plants to perfect themselves where sown. Such plants can cater for themselves in a way which transplanted ones cannot do for some time. Once got them fairly started, and dry weather is of less importance to them. They need little or no watering, as, however dry the surface, moisture will reach them from great depths. The mere damping of the surface would arrest the rising of moisture in the shape of vapour to be caught by the roots as it passed them. A rough surface, though to a certain extent it would arrest rapid evaporation from the soil, would not impede the rising of moisture by capillary attraction from beneath, as a mere wetting of the surface would do. That mere drizzling never reaches the roots, and does more evil than good, as it arrests the rising of moisture from beneath until it is itself all evaporated, and the usual course of evaporation is brought into exercise. From this great source of moisture in the bowels of the earth, fresh-transplanted plants in summer receive little or no benefit whilst the surface is moist, and it must be pretty moist, unless we plant with great balls. Hence it will be seen that even the best rules as to planting may be broken at times with advantage. Watered early Celery to prevent it bolting, and covered with half an inch of dry earth. Must wait for a change of weather before we can plant out any more. A man with a stream at hand need not wait, for he has water ready. When plants with fine balls can be raised, we do not like to injure a leaf. When that is not the case we would be inclined to dock them a little, to lessen the perspiring surface. Hoed and forked amongst growing crops; cleared the ground of early Cauliflower and Peas, and prepared for digging for fresh crops. Watered beds of Endive and Lettuces, and sowed more, also Spinach, Turnips, Radishes, and Dwarf Kidney Beans, where we shall be able to give a little protection in autumn. Other things much in routine.

FRUIT GARDEN.

Thinned late Grapes. Tied-in Peach-shoots. Watered and regulated Figs, Cherries, &c. Layered Strawberry-runners. Thinned and stopped shoots of fruit trees, as previously stated. Planted-out late Melons. Cut-back the first bed for a second crop. The second bed had been too much punished with bearing and rather dry to do much more good, so moved plants out, and part of soil to 2 or 3 inches deep. Cleaned the frame, painted with sulphur inside, and planted with strong young plants. We have also put some where a little fire heat can be given in the autumn. Successions come in well. Strawberries are suffering considerably from the drought. Even the blackbirds seem to care less for the fruit, as it has become more saccharine, and is less juicy. The crops on the whole have been good. We have noticed the trouble that some people have to obtain a crop; but it is in general all their own fault. A friend of ours has a large bed, but he scarcely ever has any fruit. He had manure water and litter at command. No plants could have bloomed better, and the bloom was perfect; but for want of the water and the litter the large crop shrivelled up. We have instanced several cases in which sterility was owing to extra and late encouragement to growth, by which fine plants were secured with soft flabby buds. We know it is often difficult to procure good crops on light land, and we approve of the plan recommended by a correspondent of adding clay to such soil. We have, however, seen fine crops secured by a simpler process still. The ground was well manured and well dug, and the plants put in the usual way, after the ground was well rolled and trodden. As soon as the plants were fairly established the ground was beaten firmly about them with large beetles when it was in a rather wet state, and then the hard firm ground was slightly littered over with half-rotten dung, and a thicker coat was put on early in spring. We never saw plants do better; the leaves were large, on short footstalks, hanging close to the ground, instead of tall staring things.

This just reminds us that no rule, however good, should be too hard driven. One of our rules as to Strawberries is to enrich the ground, dig it well, and after planting never to put a spade in it until the plants are dug down. Another rule is never to cut away a Strawberry leaf from a plant we wish to remain and be fertile, except perhaps a few dead ones at the spring-dressing. This answers well with us here, and we should look on such an operation as mowing the tops of our Strawberry-beds early in the autumn as something barbarous—quite as bad as cutting over a quarter of Asparagus in the beginning of August. But holding that idea, we must say that we have seen the scythe used in a Strawberry-quarter with very good effect. In very light soil the foliage comes long and lanky, it is frequently all spotted and brown before the fruit is all gathered, and therefore the wasted foliage cannot elaborate for the buds of the following year. When neatly cut over early a fresh batch of green leaves is produced; and these so grow and flourish that ripened and far better buds are produced on compact fresh plants before the end of autumn than ever could have been produced from the old, spotted, half-dead leaves. Only in such circumstances would we sanction the scythe or the knife; but even on such soil we shall be surprised if such a practice is much needed if the firming process is resorted to. Thus rules must bend at times to suit cases and circumstances.

ORNAMENTAL DEPARTMENT.

Potting hardwooded and softwooded plants, training flowers in beds, keeping clean, and the general routine much as last week, which see. Our labour is greatly regulated by the scarcity of water, and moving our rough surface presents a fresh point for the sun to act upon, and so far breaks the line of evaporation and conduction without doing much to prevent the free rising of moisture from beneath. We have been obliged to water some Calceolarias that were showing signs of distress, as they are heavily loaded with bloom. Geraniums are standing the drought nobly as yet.—R. F.

EXTRAORDINARY FROST.—On the night of Saturday last the thermometer near London fell to 27°, or 5° below freezing, a temperature which we believe has never before been registered in July.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

CHERRIES FALLING IN AN ORCHARD-HOUSE (*Observer*).—Your Cherry trees are, from your description, of the Bigarreau race, and your house being "forced on early in the season," the blossoms drop from the pollen not acting. Bigarreau Cherries are most impatient of heat when in bloom, and do not force well. You should remove them and plant May Dukes, but with them much care is required when forced. They should have abundance of air when blossoming.

GUANO LIQUID MANURE (*J. C. Muckross*).—For plants in pots half an ounce of guano to a gallon of water; for plants in the open ground one ounce of guano to the same quantity of water.

PLUMS IN POTS (*An Irish Subscriber*).—There is either a defect of action at the roots or you keep your orchard-house too close. What is said in answer to another correspondent to-day relative to his Cherries falling may be suggestive as to the cause of your Plums becoming yellow and falling.

SPOT IN GRAPES (*G. M.*).—The berries of your Muscat Grapes are unquestionably affected with the "spot," a disease which we consider has no connection with exposure to the light. Try removing the soil down to the upper roots, replacing it with a mixture of light loam, limy rubbish, and thoroughly-decayed stable-dung, giving also copious waterings with tepid water.

BERRIES OF COTONEASTER AND PYRACANTHA (*F. P.*).—They are not tempting in flavour, but we should certainly say that they are not poisonous. The *Crataegus pyracantha* belongs to a genus, the berries of which are really palatable. Formerly both *Cotoneaster* and *Pyracantha* were included with the Medlar in the genus *Mespilus*.

WHITE CURRANTS (*Lex*).—The White Currants you saw in Covent Garden were the White Dutch. They are produced by being grown in a fine strong loam, and by the trees being pruned on the spur system.

NAMES OF INSECTS (*T. Morgan*).—The Black Pincher is a species of ground beetle (*Harpalus ruficornis*), and is no doubt beneficial in gardens and fields, by destroying and eating worms and other soft-bodied insects. —W. (*Bees*).—It is the *Sirex gigas*. The appendage to its abdomen is used for boring into Fir trees for the deposition of its eggs.

HORSE-DUNG FOR MUSHROOM-BEDS (*C. P. Wigan*).—We would recommend horse-droppings that have been collected four months and dried in the shade, without any litter amongst them, to be mixed with at least one-third of their quantity of fresh dung.

THRIPS AND RED SPIDER ON GRAPES NEARLY RIPE (*A Many-years Subscriber*).—Fumigate the house with the best shag tobacco to destroy the thrips; paint the walls at the top of the house with sulphur, and the hot-water pipes also if they are the source of heat, but not a flue. Put a sharp fire on at night, opening the windows early. If you dislike using fire, slack 2 or 3 lbs. of fresh lime in a pail, and when pretty well slacked, mix with it half a pound of sulphur. Were we in your case, we would go over all the worst leaves with a sponge just moistened with soap water, so that the insects would stick to it, and there would be no danger of any dropping on the bunches. A man might thus soon clean a house, especially with the help of the sulphur fumes. The sponge is the safest application.

CLIMBERS FOR GREENHOUSE (*J. P.*).—Presuming that you wish for climbers of short duration, as you have named *Tropæolum canariense*, the following, in addition, will give abundance of flowers:—*Thunbergia alata* and *T. alata alba*, *Tropæolum Lobbianum* Brilliant, *Lophospermum Cliftoni*, and *Maurandia Barclayana*. We should prefer some of the more properly-speaking greenhouse climbers, for most of the above are hardly worth house-room, as *Hibbertia grossulariifolia*, yellow; *Jasminum gracile*, white, and sweet-scented; *Keanedya inophylla*, and *K. monophylla*, blue; *Rhynchospermum jasmimoides*, white, very sweet; and *Keanedya coccinea*, red. All these will do well in nine-inch pots, with ordinary greenhouse temperature.

EVERGREEN BERBERIES (*G. M.*).—Your border will just suit Berberies. Trench the ground if possible, and then work in, as your soil is light and poor, a liberal dressing of well-rotted manure or leaf mould. You will hardly be able to have more than two rows to such a narrow border, 4 to 5 feet. In the back row plant *Berberis canadensis*, *B. edulis*, *B. Fortunei*, *B. Leschenaultii*, *B. empetrifolia*, *B. heterophylla*, and *B. dulcis*, all of which attain 4 to 6 feet, and that is the distance they should be planted from plant to plant in the row. In the front row *B. Darwini*, *B. asiatica*, *B. Beali*, *B. japonica*, *B. nepalensis*, *B. sinensis*, *B. trifoliata*, and *Mahonia aquifolia* should be planted alternately with the plants in the other row. The plants should not be less than 2 feet from the edge of the bed, and the same between the rows, so that your border should not be less than 6 feet wide. One row of plants is ample for a bed 4 feet wide; but two rows look better than one, and three are better still, especially when the centre is planted with the taller, and the outside rows with the dwarfier kinds. Any planted between October and March in mild weather is the proper time to plant them. All the pruning Berberies require is to cut away in early summer any straggling shoots and such as are weak and old. They will need copious supplies of water the summer after planting in droughty weather.

SALT FOR MILDEWED VINES (*J. A. J.*).—We do not think the salt would injure the Grapes, but we would not run the risk, since it is established beyond controversy that flowers of sulphur applied thoroughly is a specific for the Vine mildew.

CROSS-BRED GERANIUM (Christine).—We can form no opinion from the parts you enclose, nor should we conclude anything unless we could see the plant, or, at least, an entire flower.

ANSWERS TO CORRESPONDENTS (J. M., Londonderry).—You are "disappointed" because you are unreasonable. Your question reached us on Monday, the very day we go to press, and it was not possible to insert an answer. No query can be sure of a reply in the next Number of our Journal unless we receive the query in the first half of the week.

NAMES OF PLANTS (A. B.).—1, *Blechnum spicant*; 2, *Lastrea dilatata*; 3, *Lastrea Filix-mas*; 4, 5, 6, *Athyrium Filix-foemina*. (*A Cockney*).—1, Hyssop; 2, Savory; 3, Pennyroyal; 4, Balm. Any gardener or cook could have told you these names, and we ought not to have our time occupied thus needlessly. (*Alpha*).—All the specimens imperfect; but we can just make out, 2, *Stachys sylvatica* and, 4, *Sisymbrium officinale*. (*W. L.*).—We have often said that we cannot undertake to name many plants from one correspondent. So out of yours we name—1, *Taxodium distichum*; 3, *Ceanothus azureus*; 4, *Spiraea filipendula*; 6, *Ruscus racemosus*; 12, *Ornithogalum scilloides*; and, 13, *Acorus calamus*. (*W. L.*).—No letter or any writing came with the specimens. Three or four perfect specimens in a card-box with a little damp moss to keep them fresh is what we desire. Numerous dry specimens we have no time to examine.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CHILLED EGGS.

In reply to your remarks and "Evesham's" as to eggs chilled during hatching, I must with all deference and with much diffidence object to your idea that the hen being off her nest several hours at so early a period in the sitting was sufficient to destroy the vitality of the eggs.

I once sent in the evening some miles for a promised sitting of eggs. They were laid by a Cochin hen running with a Minorca cock. When my messenger arrived, he found they had that morning been placed under a hen. They were, however, removed, and he brought them to me, of course quite cold. I think I had ten chickens out of that batch.

I look, however, on the general habits of broody hens as telling more against your opinion than even my case above. It is a popular notion, with perhaps a good share of truth in it, that stolen nests are most productive; and those of us who have watched hens know, that for many days during the laying of the last three or four eggs, the hen is often several hours on the eggs and then off again for as many, thus placing these eggs frequently in the same position as "Evesham's," yet they hatch. At this early date there is no real vitality in the egg. Indeed, until the appearance of blood on the third day, comparatively little change takes place to the eye of a careless observer. So many authenticated cases of success after chilling having occurred, it is wise to persevere if eggs are of value.

Can "Evesham" be certain that eggs from the same yard about the same time prove fertile? Are eggs of Sebright Bantams of less vital power?

I have this year hatched a great number of eggs that had been greased to keep them fresh; the lard, though keeping an egg beautifully fresh for months, is easily wiped off, and does not then interfere with the admission of air into the egg.—Y. B. A. Z.

In April, 1854, No. 291, Vol. XII., I gave you an account of a hen having left a sitting of eggs on the twenty-first day, and that on the twenty-second day part of the eggs were placed below another hen, after having been deserted for more than twenty-four hours and becoming quite cold, and that on the twenty-sixth day five birds were hatched, and on the twenty-seventh day three more were added to the stock. In the Number above referred to there are communications from six different individuals giving instances of eggs being chilled from six to twenty-four hours.—J. T.

SEEING inquiries as to the time for which eggs might be left during sitting without vitality being destroyed, I beg to mention the following fact. Five eggs (Silver-spangled Hamburg's), were put under a Bantam hen, which deserted them after about a week. They remained certainly twelve, and so far as I remember, twenty-four hours, and were, of course, quite cold, when another Bantam hen took to the nest. I broke one egg, and seeing some slight motion in the embryo chick within, I left the other four eggs, of which three have just been hatched, twenty-two days after the first hen commenced sitting.—W. R. J.

SELBY POULTRY SHOW.

A POULTRY Show in connection with the tenth annual meeting of the Selby, Tadcaster, and Market Weighton Agricultural Society was held on the 10th inst. at Selby. Notwithstanding the excessive heat, the thermometer being at 86° in the shade, to the great distress of the poultry, the ground was crowded with visitors from the opening to the close of the Show. The birds this year excelled both in number and quality those exhibited at any previous meeting of the Society, so that, altogether, we may congratulate the Society upon the success of their Show at Selby. There is one point in which the Society has room for improvement—viz., the pens provided for the reception of the birds, many of which evidently want renewing, being in a very dilapidated condition, so much so that they proved only insecure receptacles for the birds. The frequent escapes were a source of great annoyance to exhibitors.

Spanish were first on the list, Miss Beldon taking first with an excellent pen. The prize for Spanish chickens was withheld. Old Dorkings were a good class, though the one for chickens of this variety only produced two pens of average quality. The Cochins, mustering eleven pens, were better this year than at any previous Show. Messrs. H. & G. Newton had an easy walk over for the first prize in old birds; there was, however, some good competition for the second, which these gentlemen also eventually secured, still continuing their success by taking both first and second in chickens with very promising Buff birds. The Game classes were rather below the average, the great Game-breeder of the district, Mr. Adams, not being in competition. At this Show there are no classes for "pens" of Game (except chickens), but only for single Game cocks and for pairs of hens. Miss Beldon well deserved her first position in both classes. In the Hamburgs, as will be seen from the prize list, Mr. James Dixon maintained his reputation as amateur of these beautiful varieties, by taking the bulk of the prizes offered against very strong competition. Good Black Hamburgs and Brahmas were the prize-takers in a large Variety class. In the chicken variety class, Dorkings were first (notwithstanding the class for Dorking chickens) and Black Hamburgs second. In Bantams, Laced took both prizes—Gold first, and Silver second. In the class for Any variety of single cocks (mustering twelve pens), the first-prize bird was a very fine Dorking; the second, an equally fine Buff Cochin. In pairs of hens, Spanish, followed by Polands, had the honours.

The Ducks, Geese, and Turkeys were strong both in number and quality. We cannot omit mentioning Mr. Young's first-prize Aylesburys, which would have done credit to any Show.

SPANISH.—First, Miss E. Beldon. Second, T. C. Trotter, Sutton Hall. Commended, T. Liddall, Halifax.

DORKINGS.—First, R. M. Stark, Hull. Second, O. A. Young. Chickens.—Prize, T. E. Kell, Wetherby.

COCHIN-CHINA.—First and Second, H. & G. Newton, Garforth. Commended, E. Witty, Cottingham. Chickens.—First and Second, H. & G. Newton. Commended, O. A. Young.

MALAY.—First, Miss Beldon. Second, O. A. Young. GAME.—Cock.—First, Miss Beldon. Second, H. M. Julian, Beverley. Commended, J. Baxter, Barby. Hens.—Prize, Miss Beldon. Commended, H. M. Julian. Chickens.—Prize, O. A. Young.

PHEASANT (Goldee).—First, J. Dixon, Bradford. Second, G. Holmes, Driffield. Commended, Miss Beldon. Chickens.—First, J. Dixon. Second, O. A. Young.

PHEASANT (Silver).—First, S. Campling, Nottingham. Second, J. Dixon, Bradford. Commended, T. C. Trotter, Sutton Hall. Chickens.—First, J. Dixon. Second, T. C. Trotter.

HAMBURGH (Golden-pencilled).—First, J. Dixon, Bradford. Second, Miss Beldon.

HAMBURGH (Silver-pencilled).—First, J. Dixon, Bradford. Second, Miss Beldon. Commended, G. Holmes, Driffield.

POLANDS.—First and Second, Miss Beldon. Commended, J. Dixon, Bradford.

ANY BREED OR CROSS.—First, Miss Beldon. Second, H. Lacy, Hebden Bridge. Chickens.—First, C. Hutchinson, Selby. Second, H. Pickels, Earby, Skipton.

BANTAMS (Any variety).—First, Lord Londesborough. Second, Miss Beldon. Cock.—First, J. Dixon, Bradford. Second, H. & G. Newton, Garforth. Hens.—First, J. B. Hepworth, Hatfield. Second, J. Dixon.

GESE.—First, J. Dixon, Bradford. Second, O. A. Young.

DUCKS (Aylesbury).—First, O. A. Young. Second, T. C. Trotter, Sutton Hall.

DUCKS (Any other variety).—First, J. Dixon, Bradford. Second, R. M. Stark, Hull.

TURKEYS.—Prize, R. M. Stark, Hull.

GUINEA FOWLS.—Prize, J. Dixon, Bradford.

Mr. Joseph Richardson, Thorne; and Mr. J. O. Jolly, Acombe, York, officiated as Judges of the poultry.

GAME AND A FEW OTHER BIRDS.

In concluding my articles on birds as regards the good and injury they do, it now only remains for me to glance at those I have not previously noticed: they are the Doves, Game, Waders, and Swimming Birds.

Of Doves or Pigeons we have five wild species—namely, the Ring Dove or largest Wood Pigeon, the Stock Dove, the Turtle Dove, the Blue Rock Pigeon, and the Chequered Dove-house Pigeon. These are all seed-eating birds; their office is that of weeders, and they do a great deal of good in eating the seeds of weeds—much more than is often supposed. That they eat corn and peas when they can get them is quite true; but their feet are not made for scratching, nor are their bills fit for digging, so that they do not do so much injury as is generally laid to their charge. The grain they devour is mostly scattered or imperfectly covered, and, consequently, but a trifling loss.

Under the head Game, I class Quails, Partridges, Grouse, Ptarmigans, and Pheasants. These are also very useful birds in the field, where they destroy an immense quantity of insects, which if left would do a great amount of damage. It is this kind of food that gives the peculiar richness of flavour to their flesh. Of corn they also eat a little, but except where they are kept in too large a number for their natural food, the evil arising from them is not noticeable, but in the neighbourhood of preserves Pheasants often do a considerable injury to the crops just before harvest.

Waders are a numerous family, but rather sparingly spread over the country. I include under this head Peewits, Grey and Golden Plovers, Corn Crakes, Moorhens, and many other birds occasionally met with. Their food consists almost entirely of insects, and they are good friends to the farmer and agriculturist. It is a great pity they are so scarce; but as they are not strictly Game, and excellent eating, we need not be surprised at their scarcity. Some meadows in Kent that used to be much frequented by the common Plover, have much deteriorated in value since the destruction of the Plover's eggs, which are sold as a *bonne bouche* at 4s. per dozen, for since the almost extermination of these birds the daddy longlegs or gadfly have increased to such an extent as to destroy the turf in many places. These birds are the best I know of to keep in gardens for the destruction of many insect pests, but they are rather delicate, and require protection from cats and rats.

The Crane and the Heron are also waders, but the Crane and Stork, Spoonbill, and Bittern, are now very rare in England, while the Heron is also becoming scarce. I do not think he does any good, and the injury he commits is only that of taking a few fish.

The water fowls, as Teal, Widgeon, and wild Ducks, feed mostly on aquatic insects and seeds, and can scarcely do much harm. Wild Geese, like tame ones, are vegetarians; they are not very numerous, and I am not acquainted with any injury laid to their charge.

Sea birds, as Petrels, Terns, Gulls, Cormorants, &c., do not, I think, affect the gardener or farmer, unless it is in assisting to form deposits of guano.

With this I close my brief notices of the good and evil done by British birds, and trust that these papers have not been without some interest to a few of the readers of THE JOURNAL OF HORTICULTURE.—B. P. BRENT.

REMOVING BEES TO THE MOORS.

As the time has now arrived for removing bees to the heather, I wish to remind your readers of the very great advantage a hive taken to the heath has over one that cannot be taken there. It gives the bees at least six weeks longer honey-harvest, and I find my bees not taken to the moors always lose weight after July. The heather, I find, is fast coming into bloom, so that no time should be lost in sending the hives; and if this beautiful bee-weather continue, the quantity of honey collected will be immense, so that the bees should have plenty of room given to them before they are sent.

I will now give your readers a few directions for removing their bees to the heather. The first thing to be attended to is to give the bees plenty of room, as if the weather is

favourable they collect from the heath a very great store of honey; so the day before I remove them I place another hive on the top of the stock, when I want to join the bees on their return home to another stock and appropriate to myself the whole of their store of honey, or if I want to take the old hive from the bees and leave them in the new hive. If I want the bees to remain in their own hive I place the addition underneath, as the bees always fill the top hive first and afterwards the bottom one, and the honey in the new hive being deposited in new combs in which there has been no brood is very beautiful, and much more valuable than the honey out of old combs. Where the two hives join I tie a piece of calico securely with two strings round each hive, so that they cannot separate or any bees escape when being removed. I then raise the hives about an inch from the floor-board upon pieces of wood, and early next morning I find every bee has gone off the floor-board into the hive. I spread a piece of net or lino on a board and lift the hive upon it, and tie the net very securely with two strings round the hive, and when so fastened I turn the latter gently upside down and place it on a cloth, and then tie the corners together, so that the hive is easily carried by suspending it by this cloth on a pole across the cart; but it matters very little if suspended or not, as the combs will not break down, the hive being turned bottom upwards. The bees by that means obtain plenty of air, do not melt the combs with their great heat (being excited), and I do not find the honey run out of those cells that are not sealed over, to do the bees any injury. I let the bees remain at the moors until about the middle of September, and when brought home I put them upon the scales, and the next day I deprive them of their surplus stock (leaving the bees, combs, and honey, 20 lbs. weight, which insures their preservation until the next summer); this I consider a proper return from these grateful creatures for my kindness in having given them a change of air in such luxuriant pastures, where many tons of honey are annually lost for the want of collectors.—W. CARR, Clayton Bridge Apiary, near Manchester.

P.S.—This month has so far been a splendid one for bees, the white clover being so very abundant. Many of my stocks have collected upwards of 2 lbs. of honey on several of the days.

BEE-KEEPING IN DEVON.—No. XVIII.

A DWINDLING APIARY.

RATHER more than twelve months ago* Mr. Edward Fairbrother first made inquiry as to bees which had done well one year gradually dwindling away the following spring, and ultimately, as he expressed it, "deserting their hives" entirely. In making this inquiry he stated that his was by no means a solitary instance, and was confirmed in this a fortnight afterwards by my friend "BAR-HIVE," who testified to his having experienced the same misfortune; and whilst declaring it to be a subject of great importance to the bee-keeping community at large, appealed personally to me as being "the very person to unravel this mystery."

In reply to these appeals I did my best in the way of suggestion as to the probable and possible causes of these puzzling failures, gave such advice as seemed likely to be beneficial, and, whilst confessing myself at fault, appealed to others to aid me in endeavouring to throw light on the subject; but to this request no response was made.

Here, then, the matter ended—unsatisfactorily enough, I confess. Unprolific queens were blamed for the absence of prosperity in the hives over which they presided, and Mr. Fairbrother was told, in reply to his further inquiries as to the selection of queens, that this desirable end would most probably be brought about by his attaining sufficient apiarian skill to breed queens and select them for himself. Now all this was, as I said before, sufficiently unsatisfactory, and I could not but confess that we had eluded the difficulty rather than fairly resolved it. Hundreds of people keep bees, and make them prosper, who never saw a queen in their lives, and are probably ignorant even of the very existence of this important member of the bee community; or, if they have some dim inkling of the fact, they either confound her sex

* Vide THE JOURNAL OF HORTICULTURE, Vol. III., page 187.

altogether and invest her with the title of "king," or they provide her with a prince consort and gravely declare that "there is a king and a queen in every hive." Added to this I may state my conviction that, although there is undoubtedly an immense variation in the breeding powers of queen bees, and that in this all-important point the Ligurians possess a great and unquestionable superiority; yet, as a rule, the full breeding powers of even a common queen are seldom tested to the utmost, and under favourable circumstances nearly every queen I have met with has proved herself equal to the occasion and fully competent to sustain the population of a flourishing colony. I, therefore, take this opportunity of recording my belief that when stocks dwindle away it is seldom through a lack of reproductive power in the queen herself, but rather owing to this power lying dormant through being thwarted in some way by adverse circumstances.

Whilst cudgelling my brains to little purpose in the vain attempt to give a satisfactory reply to the query propounded to me, I little thought how soon Mr. Fairbrother's case would become my own, and that finding myself fairly confronted by the same difficulty, I must either solve the problem or bid adieu to prosperous bee-keeping. Such has, however, been the case this season, which has been to me one of continued worry, vexation, and disappointment, both English and Italian bees having been equally at fault. Had I not already thoroughly tested the good qualities of my Ligurians, I might probably have pronounced them worthless, and had I met with such ill-success on their first introduction, I would scarcely have troubled myself about naturalising them. Thus, then, the matter stands. Although all possessed of young queens, many of them sprung from a race proved to be far superior to the ordinary species, my hives have gone from bad to worse, until some with the purest and most valuable queens have threatened to become altogether extinct, and none approached to anything like the prosperity which they have hitherto attained in far less favourable seasons. All my endeavours to restore weak stocks by the hitherto-unfailing process—exchanging brood-combs with more populous ones, turned out of no avail, whilst I continued to receive the most deplorable accounts of the few colonies I had been induced to part with. Repeated examinations of the interior of my hives led only to the same conclusion, that the queens were in no case in fault, but that comparatively few of the eggs laid by them developed into bees. Setting this down to the account of the cold nights we at that time experienced, it may readily be imagined how I longed for warm, nay, for very hot weather, when no low temperature could exist even in the most thinly-populated hive to interfere with the development of the young larvae.

Thus passed the spring months, until at length in May it became evident that the bees themselves were incompetent to remedy the mischief. Many of the combs had become mere masses of abortive brood, which the bees allowed to remain untouched, apparently overpowered and paralysed by the magnitude of the evil, and I was irresistibly impelled to the conclusion that something must indeed be done. By way of experiment I took one of the worst combs, opened every sealed cell, and by repeated and continued jerks over a sheet of paper succeeded in dislodging a vast quantity of a dark brown slimy matter, from which arose a most unpleasant smell. Having by this means and the use of a damp flannel removed as much as possible of the offensive substance, I returned the comb to the hive, and awaited with anxiety the result of my experiment. Before very long the bees set to work, and having apparently purified the comb, the queen next entered upon the scene, and soon filled it with eggs in the most methodical manner. This, then, thought I, is the right course to pursue. My little labourers are evidently appalled at the magnitude of the task, and if I only lend them a helping hand they will do the rest themselves. I at once set to work: comb after comb was, at the cost of infinite labour, cleared and replaced; and I looked forward with confidence to the time when the development of what I thought must now be healthy brood would replenish my depopulated hives, and enable me once more to rejoice in the possession of a flourishing apiary. In this, however, I was grievously disappointed. It soon became evident that the bees hatched were even fewer than before, and that at

the cost of so much time and trouble I had only given an impetus to and actually accelerated the downward progress of my apiary!

During all this I had from time to time made a few spasmodic attempts at queen-rearing; but such was the weak state of my colonies, that it was with difficulty any of them could spare a few bees to stock even a small nucleus: and of the royal cells that were formed, so great a number turned out abortive that June was ended before I had raised more than a single queen.

When June was nearly at a close, and I found myself in the same dilemma, I was fairly at my wits' end. I thought of Mr. Edward Fairbrother, and, like him, confessed myself fairly beaten. Never had I met with such a case, or even anything approaching to it; neither could my apianian friends assist me by suggesting a remedy for what was to them altogether unprecedented. All their bees were in the most flourishing condition; and one in particular fairly told me that he believed he had more bees in one of his Ligurian stocks than I had in my entire apiary. Can it, therefore, be wondered at that, in the bitterness of my heart at this humiliating contrast, I was almost tempted to wish that I had never become—A DEVONSHIRE BEE-KEEPER?

DRIVING BEES.

I OBSERVE in your No. 118, that "A. B. C." has been unsuccessful in driving and transposing. I will, therefore, give him a little of the practice I have had. Last year I drove three hives. One proved successful, but the other two did not; and the next day I was rather astonished at seeing the three hives fraternise, the bees going from one to another. One of them, it turned out, had no queen, and, consequently, it was robbed, and the bees joined the robbers.

Driving does not always succeed, as sometimes the bees will not go out at all, and I find natural swarming is better than artificial; but you may save time and trouble in watching by driving. One of my last year's Ligurian queens not breeding good bees, I put on a drone-stopper, and it appears to have prevented her from swarming, as the bees have come out once or twice, and lately have been hanging out; but last Friday (July 10th), I observed many of them going to the next hive, and no fighting going on. I have, therefore, transferred this hive, and have added a large quantity of bees to a young Ligurian queen. I find bees join better, and with less fighting at the latter end of the season than now. The other day I had a very fine Ligurian queen come off, making the third swarm; and as there was not enough of bees for this time of the year, I fumigated one of the hives that I suspected to have no queen, as there were so few bees going in and out; but I found the queen and destroyed her, as she was evidently no breeder, and then put the swarm into the live with comb, and joined the bees together. On the next morning I observed a small cluster of bees under the alighting-board, and on looking into them saw the queen, and got her into the hive. She very soon came out again, and I therefore put her with the few bees that followed her into an empty hive, and on going home the next evening was told I had another swarm, but on examination found the hive empty, and also the other live, showing that the queen and the few bees had left the hive again. I did not find her that evening, but succeeded in doing so early the next morning in the place where she had alighted on the day before, and, therefore, I hived her again, but at night found she had gone, and have not been able to find her since. I fancy the bees would not have her because she would not be impregnated.

Can any of your apianian correspondents inform me how many days piping may be heard before swarming, as I have a swarm that has been piping for these four days? The people here say it says "out," meaning the old queen has gone.—A. W.

OUR LETTER BOX.

LARGEST BROOD OF DORINGS (*M. P.*).—The most numerous we ever knew comprised seventeen chickens. The hen had sat herself in the thatch of an outbuilding covered densely with ivy.

WEEKLY CALENDAR.

Day of Month	Day of Week	JULY 28—AUGUST 3, 1863.	Average Temperature near London.			Rain in last 36 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 75.4°, and its night temperature 51.5°. The greatest heat was 92°, on the 1st, 1846, and 2nd, 1856; and the lowest cold, 34°, on the 1st, 1856. The greatest fall of rain was 1.39 inch.

BOILERS.

IN constructing a hot-water apparatus, a good boiler is the first consideration.

In my opinion the merits of a boiler for horticultural purposes, should be

measured in the following order:—1st, It should present a large surface to the direct action of the fire. 2nd, It ought to need little water to fill it. 3rd, It should be made of a material not likely to wear out soon. 4th, The base or bottom should be double the width of the top. 5th, It should be so constructed that it will not be soon choked with soot, and should be easily cleaned out. 6th, It should be of easy access for being repaired. 7th, It should heat quickly. 8th, It should be easy of management. 9th, Its furnace should burn any description of fuel. 10th, It should require but little attention. 11th, It should be capable of being regulated so as to heat a little as well as a large amount of piping without any waste of fuel. 12th, Provision should be made to clean the inside of the boiler, to keep it clear of sediment.

Some of the points named convey their own meaning, but a few remarks on each may not be out of place.

On point 1st, I may observe that the parts immediately over the fire receive the greatest heat, and those parts ought to be stronger than the rest; but whether the expected saving likely to accrue from thus providing against wear and tear, would more than balance the increased slowness of heating, has yet to be proved. Water in a tin saucepan is sooner heated to a given point than in a copper one; brass is some time longer in heating, and an iron pan longer still: therefore, it is only common sense to imagine a boiler side or bottom half an inch thick would heat the water in contact with it quicker, and a greater quantity, than one double that thickness. I dispute the claims of a boiler to preference because it exposes a large amount of surface to the action of the fire. It would be well to discriminate between direct and indirect action. The parts immediately over the fire I think may be considered direct, and those receiving the flame or heat after it has been in contact with another part of the boiler indirect. The one has double the heating power of the other. The fire in the first place would melt brass (1869°), whilst in the other it would not melt lead (594°). Water, however, cannot be heated to more than 212°, a few degrees more or less according to the pressure of the atmosphere; yet it does not follow that a material capable of being heated by a common fire to a temperature of 1141° (Daniell), will not boil more water in a given time than the same material at half the temperature. A boiler, therefore, exposing 10 feet of direct, and 20 feet of indirect surface to the action of the

fire, will not heat more water to a given temperature than one with 15 feet of surface directly exposed to the action of the fire. It does not follow that a saddle boiler with 12 feet of direct, and the same quantity of indirect surface, will heat as much surface as a tubular boiler with 12 feet of direct, and 48 feet of indirect. The tubular in this case would heat one-third more water than the saddle boiler; but a saddle boiler with 30 feet of direct, and the same quantity of indirect surface, would heat more water to 212° than a tubular boiler with 10 feet immediately over the fire (directly exposed), and 50 feet of indirect surface.

On the 2nd point I need not comment, for it will be evident that a boiler holding but twenty gallons of water will be sooner heated than one holding forty gallons. Large boilers holding a large quantity of water must be wide inside, from one side to the other, but a boiler holding but little water must have its parts narrow. On this point I need not further enlarge, beyond stating that the heating capabilities of a boiler are nearly as much dependant on the water it contains as on the surface exposed to the action of the fire. A boiler holding forty gallons of water cannot be so economically heated as a boiler holding but twenty gallons, both having the same amount of heating surface. The former gives heat where it is not wanted, in the boiler, the other in the pipes within the house required to be heated.

I may observe on the 3rd point, that the best metal adapted for boilers appears to me to be cast iron. Water prevents metals from being heated to their highest extremes. For instance: lead melts at a temperature of 594°, but a lead tube filled with water, hot or cold, will not melt, though exposed to a red heat (1077°) temperature. To calculate, therefore, that because lead melts at 594°, and iron (cast) at 2786°, the last must necessarily last longer than the other as a boiler is erroneous. A lead pipe filled with water will last longer than an iron one. I have an instance of this in a boiler for brewing purposes with a copper bottom and lead at the sides. The copper and the lead have been in use for near half a century, but an iron one not so frequently used as the other was corroded through in half the time. It was, however, a wrought-iron boiler. Still, as lead is so peculiarly liable to melt and get out of shape, copper too dear, brass little less expensive, and wrought iron soon worn or corroded through, the preference must be given to cast iron. When of good quality, and pains are taken to secure a good cast, this iron is undoubtedly the best and cheapest material that can be employed for making horticultural boilers.

A cast-iron boiler properly cast is calculated to serve a young man his lifetime, providing he will give a good price for a good article. Cheapness is mostly obtained at the expense of quality, and boilers are no exception to the rule.

The 4th point may seem ungainly. Why have a boiler larger at the bottom than at the top? Because when a boiler is thus wider, a larger amount of surface is presented to the immediate action of the fire than there

would be providing the boiler was of an equal width throughout. For instance: a cylinder with a base of 3 superficial feet exposed to the direct action of the fire will not heat so soon as a conical boiler (supposing them both to hold the same quantity of water), with a base of 6 feet. Another reason why I would have the boilers wider at the bottom than at the top is this—When an upright passage is prepared for heat to pass through, it does so without parting with much of its temperature; whereas if the surface were exposed but inclined, the heat would run against it, as it were, in its never-failing passage upwards, and it would lose some of its temperature with ten times greater rapidity by contact than by radiation in a hurried passage. Everybody knows that an upright chimney is never so hot as a horizontal flue, the reason being heat ascends; in the chimney it is free, in the flue it is continually striving to ascend, and burrs, so to speak, against the flue top its entire length, consequently loses heat continually. In a boiler it is pretty nearly the same. A saddle boiler loses almost all the heat of the fire after its first contact with it, for when the flame goes along the side or over the boiler the top of the flue is heated more than the boiler. At the turns in the flue this is hotter, because the current of hot air is checked by an obstruction.

Another reason why I prefer a boiler wider at the bottom than at the top is, the circulation is more rapid. After water is heated the sooner it passes into the pipes the better, and the smaller the opening to admit the water from the boiler into the pipes the more quickly will it pass into them. By having the boiler top narrower than the bottom, the water is compressed similarly to a swollen river passing through a bridge, and everybody knows the current is stronger there than anywhere else. In a boiler, by heating a large body at the bottom of the boiler, and then causing it to pass through a narrow passage, we obtain double or treble the velocity. Let any one doubting this connect a piece of 1½-inch pipe to the boiler-nozzle instead of a four-inch, and he will find the hot water rush through it at six times the speed that it does through a four-inch pipe.

Water exposed to heat expands, becomes lighter, and ascends, and the quicker we get it out of the boiler after it is heated into the pipes the more heat we obtain. We do not want boiling water in the boiler and cold water in the pipes: therefore, the sooner hot water is replaced by cold water in the boiler the more economical is our heating apparatus. The water cannot come too freely into the boiler, it cannot go too soon out. I infer from this that the water should have double the space to come into the boiler as to get out.

The 5th point resolves itself into this: A boiler covered with soot and dust will not heat well. Upright flues are not so liable to hold soot as horizontal flues, and where the draught is quick the necessity to clean is not so great as when the draught is sluggish. Boilers, the parts of which are narrow and set horizontally, are very troublesome to keep clean, and when the flues have many bends more soot will lodge. Dirty flues reduce the heating power one-third, or, in other words, a clean flue will heat any surface one-third more quickly than a dirty flue with the same amount of fuel.

On the 6th point I may observe that many boilers are expensive because they cannot be repaired. A cast-iron boiler cast solid in one piece cannot well be repaired when it is worn through or burst, but a wrought-iron one can. Cast-iron boilers that cost £20 very often have defective places in them, and when these give way there is no remedy but a new one. This very often causes a serious loss to the owner and more mortification than enough, for it is not pleasant to see an expensive boiler worthless because it has a small worn place in it, or a crack that could, would the material allow it, be repaired for a twentieth part of the cost of a new boiler. It is quite possible to have a cast-iron bottom rivetted to a wrought-iron top.

The 7th point will be obvious to all. The sooner a boiler, or rather the water, becomes heated the better for meeting emergencies consequent on a fickle climate, for at times little heat may be required; but on the sudden, without previous warning, severe weather sets in and more heat is wanted. The structure to be heated has been kept as cool as circumstances will permit to save fuel and for the well-being of the subjects; but there is a minimum temperature allotted to all plants, and to subject them to one below this

is injurious if not fatal: therefore the heating apparatus should be capable of attaining a certain temperature before the external temperature has reduced the internal temperature to a point when fire heat would be too late to secure the safety of the inmates of the structure, besides the anxiety of mind consequent on waiting whilst a boiler is heating, and the mortification attendant on observing the temperature lower after the fire is started instead of heating sharply. A slowly-heating boiler is more costly than a quickly-heating boiler, but, of course, much depends on the draught. A boiler heating slowly through a bad draught, and another heating quickly with a strong draught, will be about equal in cost. A boiler, therefore, ought to heat quickly without wasting any heat or burning more fuel than a slowly-heating boiler.

The 8th point conveys its own meaning. A boiler should be under control like a horse. It ought to keep the pipes either warm or hot, and consume only half the fuel for the former temperature than for the latter.

Point the 9th is perhaps the most important. A boiler that burns coke will be more costly than worthy where coke is 21s. per ton, and other fuel can be had for 5s. per ton and afford the same result.

Such a construction as a universal boiler never has been, and perhaps cannot be, manufactured. A boiler that will heat readily by wood would suit in some places, by coal at another, and by coke at a third; but a boiler that would heat with a combination of each is much wanted.

The 10th and 11th points are solely relating to economy.

Point 12th is well nigh impracticable. Neither is it necessary to provide for the cleaning of a boiler from the inside, for there is no steam in a boiler, therefore no incrustation of the iron. No one ever, or very rarely, saw any incrustation on a boiler or pan without a lid; and in a boiler closed from the external air and full of water little or no incrustation takes place, providing the sediment resulting from corrosion is let out before the particles are united to the boiler. Boilers are more liable to become choked from corrosion and the lodgment of sediment in the lower parts and the return-pipes than to become blocked-up by incrustation. In fact, any boiler (I am not writing about steam boilers) will be corroded through sooner than choked by the incrustation resulting from the use of the hardest water. Providing there is a hole drilled in a boiler at its lowest point with a pipe protruding from the brick-work and a tap, that is all that is required to clean a boiler.

—G. A.

(To be continued.)

JOTTINGS FROM PARIS, 1863.

EVER since my return there has been one incessant round of flower shows, and to chronicle these I have been compelled to put on one side the few stray notes that I had made on some of the notabilia in the gardening way which struck me this year; and as I have ever found that any information to be obtained on the subject of ROSES could be had from either the Verdiers or M. Margottin, I managed to make a little trip to Bourg-la-Reine, and have a couple of hours' chat with as genuine a rosarian and as honest a man as there is on either side of the channel. Unfortunately I was nearly three weeks too soon to see anything in flower, and was somewhat disappointed; but I then learned what perhaps I ought to have known before—that it is not in the early spring that they are so much before us, but as the month of May advances; and it brought to my mind what struck me at the time as curious—that a gentleman who kept a regular thermometric account of the temperature at different places, once told me that it was astonishing how little difference there was between Paris, Lisbon, and his own place up to the end of April, but that after that it became very perceptible. Knowing that we have ROSES in bloom in June I expected to find some at least in flower, and was surprised to find that the buds were no farther advanced than some in my own garden when I left home. I was content then to have a view of one of the most beautifully even lot of ROSES (as standards) that I ever saw, and to have a good chat with my old friend and his amiable son.

We were tolerably well agreed as to the merits and demerits of the various Roses which the previous year had produced, the unquestionable excellence of a large number of them having been recognised in France as well as here, there being, however, the predilection for dark Roses such as *Vulcain*—a taste we cannot as yet arrive at on our side of the water. He had already bloomed our fine English Rose *John Hopper*, and expressed himself greatly pleased with it. Madame *Clemence Joigneux* is said to be something like it; but I have not seen that variety, and so am unable to say whether it be so or not. M. Margottin spoke in high terms of *François Lacharme*, which we have all learned on this side of the water to esteem highly. By-the-by, I should be glad if your rosarian subscribers would test this as to its perfume: a bloom that I cut the other day had the most peculiar fragrance I ever recollect to have met with in a Rose, it having a most distinct flavour of lemon, almost like the Sweet-scented *Verbena*, so called, combined with attar of Roses. It may have been owing to some peculiarity of soil, but it certainly was the most deliciously scented Rose I ever smelt. Charles *Lefebvre*, Madame *Boutin*, and other flowers which have established themselves in our good graces were also highly spoken of.

We had a long talk on the subject of seedling Roses, and his treatment amply explains the fact that so few indifferent Roses have been let out by him; in fact, if ever he does let out a Rose of second-rate merit, I believe it to arise from the capriciousness which attends the growth of this lovely flower in all seasons and places. A great deal has been said, for example, against *Boule d'Or*. Well, it is in some seasons difficult to open; but I have cut this summer from a standard on the *Briar*, as fine and highly coloured flowers as I ever saw at *Bourg-la-Reine*; making one exclaim, If only one had such blooms every three years it would be like running the blockade, one hit would amply repay two losses.

The plan which M. Margottin adopts with regard to seedlings is, when he sees one of promise to bud it on two or three stocks for the first year. If it succeeds well on these, he next year increases the number, so as to have about twenty on trial. If it does not answer his expectations he throws them away, keeping only one or two; but if it maintains its character it is still further increased, so that four seasons elapse before it is let out; and it sometimes happens that even then it belies its promise, and he is obliged to throw it away. We saw one variety which he had grown for nine years, and which he intended to have discarded; but last season it gave some beautiful blooms, and so he has tried it another season. Another, with very beautiful blooms, had wood of so "villain" a character, so like the wild *Briar*, that he could not grow it, for the point at which he aims is robust habit combined with excellence of bloom. He considers that no beauty will warrant his sending out a sort deficient in constitution. We know that Jules Margottin, Louise Odier, Louise Margottin, &c. are excellent in this respect; and I have no doubt we shall find the same character pervading his new ones. What use is there in growing, for instance, such a sort as *Madame Furtado*? You may obtain an excellent flower, and it is a beauty when caught well; but then nine out of ten of the plants are yellow and weakly, and disfigure the bed in which they are growing.

M. Margottin had heard nothing of the new Roses of other growers, but he has three of his own which he believed would be found to be acquisitions. Two of these he has since forwarded blooms of to me, and one of them will be figured in the September No. of the "*Floral Magazine*." It is quite a novelty among *Bourbons*; a seedling of Louise Odier crossed with some dark Hybrid *Perpetual*, retaining the shape of its parent, of a dark crimson colour, and having what is very rare in this class—a most delicious fragrance. This he has named after myself, and will be let out this autumn. Another was a large crimson-flowered Hybrid *Perpetual*, a seedling from *Souvenir de l'Exposition*, and, like the preceding one, is of very vigorous habit, and I believe will be found an acquisition.

M. Margottin's garden is returning to its former well-stocked state, having recovered from the severe winter of 1861 which killed so many of his seedling plants. I never saw a finer lot of plants than those which he has now in it,

and I deeply regretted I had not been there three weeks later to see them in bloom.

I also paid a visit to M. Charles Verdier, and from him learned that it is his intention, if possible, to send over a collection of *Gladioli* somewhere towards the end of this month; but I fear there will not be any shows at which he can exhibit them. He has gone largely into their growth, as may be gathered from one fact—that he will have nearly a thousand bulbs of *Reine Victoria* (the finest white grown) for sale this autumn, and that he will be able to reduce the price to about three francs a-bulb; and as he is most careful in all connected with his business, *Gladioli*-growers would do well to bear his name in mind. His address is *Rue Marché aux Chevaux, Paris*. I could glean nothing about new Roses from him. The pleasant task of reporting on them I must leave to some other more fortunate traveller than myself, and conclude with again acknowledging the great kindness and attention I received from all with whom I came in contact in the horticultural world.—D., *Deal*.

KNOWLEDGE DESIRABLE FOR GARDENERS.

"I am a young gardener, and would like by-and-by to obtain a good situation. Meantime I should like so to improve my time as to fit me for such a situation, if I should happen to procure it. I want to know, therefore, what are the things that are most requisite for a gardener to acquaint himself with. Botany, I know, is necessary; but I think there are other things to be studied even before botany. I do not think it would benefit a gardener if he were to study ever so long at botany if he could only read and write.

"I know that gardeners, as well as other tradesmen, are nothing the worse of knowing a little of everything; but still there are some things that they should know most about, and these things are those on which I am particularly desirous of information.

"I learnt a little of Latin at school, so that I can understand many of our botanical names better than a good number of gardeners. I have heard even head gardeners giving such absurd names to plants, that I often would have liked to have corrected them only for fear of giving offence.

"If you do not think my letter very foolish, perhaps you would be kind enough to reply to it in your answers to correspondents, and tell me what I had best study in the meantime. If you do think my letter too foolish you might tell me so, and that itself will be a lesson to me.—D. B."

THE having replied in a short note as to the purport of your letter when we received it must, with having little time on our hands lately, plead our apology for not sooner entering upon the subject more in detail. We by no means imagine that the matter of inquiry is at all foolish, but consider, on the other hand, that scarcely anything could be more sensible. The difficulty in replying as to the branches of knowledge most important for a gardener to study, arises from the great difference in taste and mental constitution, in unison with the well-known fact that we will naturally excel in those departments that are the most pleasing and interesting to us.

You are quite right in coming to the conclusion that the more a young man knows the more likely will he be to succeed as a gardener; but then it should never be forgotten, that the success will be even less owing to the possession of knowledge, than to the power and generalising tendency of bringing that knowledge to bear upon and regulate the operations of our everyday life. Many a man possesses wondrous stores of knowledge, but for want of this simple adaptation quality they are of little more use to himself or others than the hoarded riches of the miser. The farmer dearly values his huge piled-up heap of manure in the farm-yard, not for the good it will do there, but for the effects it will accomplish when incorporated with the soil of his fields. We must try with all our gettings to avoid being a mere piled-up heap of good manure. "I know it is in him! I know it is in him!" used to be the ejaculation of a loving father as to the abilities of an only son, that others of our village community looked upon as anything but particularly bright. "But what if it never comes out, Tom?" was the reply of a messmate. Ah! the coming-out was the grand proof, and the proof never came. Hence men of but

limited acquirements, but possessed of this coming-out—this adaptation-to-circumstances principle—have been more valued for their services, and done more good in their day and generation, than some great philosophers and encyclopædists of knowledge, whose minds seemed such a vast storehouse of information that the bringing-out of that information upon any one object of utility seemed to be unworthy of or beneath their serious consideration.

Again: We should never forget—(though the possession of great stores of knowledge is ever compatible with that knowledge being rendered subservient to the common operations of everyday life, and the understanding of the principles on which such operations are based will not only enable us to perform our work better, but give to work and toil an elevated pleasure)—that still an intimate and thorough acquaintance with a few branches of knowledge will be more useful and satisfactory than a mere general passing acquaintance with many departments of science; and therefore, whilst despising no field of investigation, the young gardener will act wisely who devotes his attention chiefly to those pursuits for which he feels he has peculiar aptitude and taste, and which will be most useful to him in elucidating and explaining the operations of his everyday life.

Before alluding to some of these we would clear away one or two misconceptions. The first is, that a gardener cannot be a good scientific botanist without a good knowledge of Latin and Greek. No doubt such knowledge would be desirable, but not at all likely to be general until employers show their appreciation of such acquirements by a suitable remuneration. It is sufficient to disprove this misconception to state, that many good practical botanists never had the privilege of acquiring even the rudiments of a classical education. The second misconception is, that the knowledge of these classic languages is necessary to the right pronunciation of the botanical names of plants. The man who pronounces these according to the rules given by London and others, will often do so more correctly than the mere classical scholar, but unacquainted with botanical nomenclature. It is not such an easy matter to decide upon the true pronunciation; as in our young days, at least, the sound emitted of the same word was often very different in Edinburgh from what it was in London, and in such cases it is generally best not to run counter to the stream, but to get into the habit of using the pronunciation that is most popular in your neighbourhood. In matters of no moment there is no advantage in mere singularity, though, no doubt, the advocates of the different systems could argue lustily and learnedly on the matter. And, lastly, though we trust the oldest gardeners that know themselves will ever be humble enough to learn, still it is the natural position of the youth under such circumstances to receive rather than to impart instruction; and when young people venture on the delicate ground alluded to by our correspondent, it should ever be done, even as to the pronouncing of a name, with the humility and kindness of a disciple, and not with the assumed pedantry of the pedagogue. In the one case the young man will rarely fail to secure the warm respect of one who may have much in his power to advance his interests; in the other case he is too apt to arouse a feeling which thus finds muttered utterance, "He is far too knowing to learn from me. Let him alone—why should I bother?"

Some latitude, therefore, should be given as to the mere pronouncing of botanical names of plants, though the young gardener should ever aim, not only at pronouncing them, but writing them correctly; and though we should ever look on a knowledge of botany as a great advantage, and still more a great source of elevated pleasure, still we do not consider such knowledge as the first essential necessary, because we well know that among the employers of gardeners there are very many who will excuse a comparative ignorance of botany, who will not even find their ears tingle at the most unorthodox pronouncing of the name of a plant, who will be slow to find any excuses for rickety plants, half-filled flower-beds, a want of crisp vegetables, and a deficiency of ripened, perfect, well-flavoured fruit.

Though well aware of our inability to mark out a course of study that would be generally applicable as the best for all learners, we have no hesitation in propounding in the first place to the young gardener the importance of being a first-rate workman in all gardening operations, and the

thorough comprehending of all the details of these operations, not deeming even the simplest and the minutest of these beneath his careful attention. These matters were more attended to when the gardener had to go through his regular course in different departments. The division-of-labour principle has so far interfered with it, that you will now more frequently meet with a first-rate budder, propagator, plant-grower, &c., than with a man who is generally conversant with all gardening operations. This all answers well enough in commercial establishments; in fact, they could scarcely be conducted without it; but it will not answer in a gentleman's garden, where one man must superintend and take an active part in all operations.

It is no uncommon thing to meet with intelligent youths that have lived in large gardens, that would cut a sorry figure with spade, hoe, scythe, knife, hammer, or mowing machine, when placed in juxtaposition with a common labourer. Now the young gardener ought not to be satisfied until he equals, nay, excels, the labourer in the quantity and the quality of his workmanship. It must be a galling thing for a man looking out for a master's place to see a labourer sent to finish the work which he left in a muddled unsatisfactory state. We knew an otherwise bright young fellow to whom the sight of a spade was like a nauseous dose of medicine in prospect. For the life of him he could not turn over a five-feet flower-bed without leaving one side some 6 or 8 inches higher than the other—aye, and he would plant it too in that condition. He had passed his apprenticeship and journeyman's in stokeholes, potting-sheds, and greenhouses, and knew as little about a scythe as the man who never saw one. Now, much of the neatness and the comfort of a gentleman's garden depends on the superintendant being practically conversant with the best mode of doing everything, and the quality and the quantity of work that ought to be done in certain circumstances. I once heard a pretty quarrel between a mistress and her maid-servant; and the latter, stung into casting what she supposed withering reproaches, declared, "I took you for a lady. If I had known that you had previously been a servant I would never have served you, that I wouldn't." Probably the mistress knew too much, and possibly expected too much. The gardener in a gentleman's place is merely a servant with helpers under him, and he will best discharge his duty to both by possessing, not merely a theoretical, but practical acquaintance with all gardening operations. Aim, therefore, at being an expert and a ready workman, and you will never stand still for a tool. Do not be content whilst a labourer can do work better than you can.

In connection with the use of tools, we would advise obtaining as soon as possible as much knowledge of mechanics as will enable you to do work well at the least wear and tear of bodily energy. Two men will each dig a piece of ground equally well; but the one will not be tired, and the other greatly distressed, because in the mode of inserting the spade there was more resistance to be overcome, and less leverage power to overcome it, and so with many other operations. A slight alteration will often cause a barrow to wheel lightly instead of heavily. One man will so set a scythe and regulate the handles that he will mow with his body merely slightly bent, another will not work unless his body is bent over the scythe as if he meant his nose to kiss the ground. The very posture, independently of the working, is fatiguing, and could scarcely be endured but that people get used to anything. And so with many other tools. If work is done equally well, the greater ease with which it is done ought ever to be a recommendation.

Again: As a security against neglecting simple details, we would urge the importance of keeping a memorandum or diary of all operations, especially of sowing, planting, gathering, changes of temperature produced either naturally or artificially, &c. These will be of great future advantage, and will tend, from showing what is required in an establishment, to dispel the illusion that some young men seem to entertain—that the growing a few plants and flowers is all that is required in gardening. The man who thoroughly masters these little matters may be a most successful gardener though a stranger to all the "ologies"; whilst the man who neglects them, or considers them unworthy his notice, may be a very poor gardener, though a Latin and a Greek scholar, and a learned philosopher besides.

Then, again, we would advise our young friends, in their working hours and in their studying hours, to aim at being methodical. The man who has no method in his work will in general have no method in study, and will, most likely, not do great things in either. We fear there is a growing tendency to want of method. Our boasted improvements have lessened the necessity for close uninterrupted attention, and hence there is frequently doing and undoing, undoing and doing, and never finished. The motto might well be inscribed on every garden tool-house—"In doing work, avoid making work." One man will go and do a job, and you will never see where he has been. Another will make such a mess that the first job was nothing to the jobs which he made. You will never lose sight of his track from the rubbish and the messes he leaves behind him. The thus making work is ever apt to keep people in a muddle. In most gardens there is quite enough of work for even method to reach. There is a man you tell to go and do what is necessary to a series of flower-beds that he knows all about as well as you do. He thinks a moment, for he is a man of method; and away he goes, taking hoe, rake, tyes, stakes, broom, and basket or barrow with him. You tell another man to do a similar job, and off he starts with his hoe. He has been chaffed for thoughtlessness, and, ere long, he sneaks to the tool-house for a rake chiefly for the edges of the beds. By-and-by the journey is repeated for tyes and little sticks, and ultimately there is a double journey for a broom and a barrow, to the no small wearing of shoe leather. Suppose that these men continue in these marked habits, would we not expect to witness a very different result, when each had a separate charge with a similar amount of labour power under him? The want of method, more than the want of knowledge, is often the cause of want of success.

And the same rule will hold true as to success in study. A dip at this, and an hour at that, will never enable a youth to master any one subject. Change is pleasant; but make it all change, and how is it possible to attain concentration of thought and of energy? Some have recommended devoting the hours of the evening, or at least the different evenings of the week, to different branches of study. We know very little, but judging from our own experience, we should imagine this plan to be all a mistake, so far as the common average of working men is considered. We would recommend, instead, to take only one chief subject of study in hand at one time, be it grammar, arithmetic, mathematics, systematic or phytological botany, geology, &c., or whatever it was, and stick tenaciously to it until it was so far mastered that we could count and report our progress; and in the meantime take up seriously with no other subject, except such as would give cheerful relaxation—as music, the newspaper, or even a little of light reading, as a good novel. The mind cannot always be at full stretch. It, as well as the body, demands change and relaxation. This relaxation will soothe and refresh, just as a stimulant acts on jaded physical energy. In both cases the stimulus must be under control, or it will become the master instead of the servant. Taken in moderation, it will relieve and brace the mind for further energy. Taken in excess, the mind becomes unfitted for sustained and concentrated thought. We have known young men allowing themselves half an hour of relaxation, and devoting each evening of the week to a different purpose; but by the time the regular night came round, they had pretty well forgotten what they had acquired, and on the whole made little progress in comparison with those who devoted a month or two at a time chiefly to one subject.

But for our correspondent being a Latin scholar, we should say that, next to a good methodical workman, the young gardener should be well up in reading, writing, and arithmetic. A good education is a great advantage. The want of it in these days need be no barrier to the youth of resolute determination. Some of our ablest, most intelligent gardeners can look back to the time, when, as they handled the fire-shovel, they could scarcely spell their way through a simple sentence. What they have done others may do. The educated youth will have the advantage if he do not think so much of his learning as to make him careless and inattentive. In a previous article we hinted that education, with a little capital or without it, might do

better than learning to be a gentleman's gardener; but the field offers something like a prize to the comparatively uneducated youth of humble means, who resolves to learn and triumph over all difficulties. With the ability to read, write, and keep accounts, he possesses the keys to unlock every avenue of knowledge. As to reading, it is next to impossible to speak well, or with clearness and elegance, without being able to read well. Young men should, therefore, accustom themselves to read out with the voice, and not merely with the eye. This is apt to be forgotten in retired country places; but if it cannot be done in lodgings it ought to be done out of doors. There is great benefit every way in thus giving free utterance to the voice. Just as in singing or reciting soul-stirring poetry, not only the matter but the manner and the idiom of the author whose sentences we read out become more impressed on the memory; and thus reading well is not only a chief means for enabling us to speak well, but the best preparatory study for enabling us to write correctly.

Reading must ever be the chief means of increased information to the young gardener. Writing down what he knows is one of the best agents by which he can plumb the depths or the shallowness of his information, and is often the only agent he can use for making his knowledge influential upon others. That writing is the best that can be read as easily as print. All fine flourishes of penmanship should, therefore, be generally avoided, unless for some particular word of importance. No capital letters should be used, except for the word beginning the sentence. The shorter the sentences are, the more pleasant and perspicuous the reading. All contractions should be avoided, as "I've" for "I have," "sd" for "should," &c. Old friends may do such things with each other; young gardeners should aim at fullness, plainness, and distinctness. Be anxious to state clearly what you have to say, and finish when you have done. I need not speak of the importance of spelling correctly; the best aid to this will be reading good authors slowly, with an occasional turn-up of the dictionary. A pithy, well-written letter is a great recommendation where a servant has to correspond frequently with an employer. If he aims at elegance and correctness, and is at all young, he should study the grammars with their respective keys, of either Lenney, or Cobbett, and Lindley Murray, and then he can scarcely fall into the common errors of joining plural substantives with singular verbs, &c. We know men that write very elegantly, that never got a lesson in grammar except what they gave themselves, and now they can smile at the crudeness of the composition of even a Queen's speech to her parliament. No man will write easily, however, who is ever thinking on grammatical points. We are told that other men write very correctly who never learned a bit of grammar in their lives. They read the best authors carefully, and learned to write with equal clearness and perspicuity, their chief guides being clear expression of ideas, natural sequence of these ideas, and a pleasing impression and clear comprehension by the ear when the matter was read aloud. A writer who cannot make his subject clear to himself must appear in cloudland to everybody else. With nothing but the ear and common sense to guide him, along with the helps above alluded to, an intelligent man will make few errors in composition, though he knows little or nothing of the rules of grammar. A careful study of the best authors will after all be the best teacher in this respect.

In speaking of the best authors, I would not include some of the most popular authors of the day, who, by high-sounding rodomontade and abundance of low slang, have done so much to injure the fine terse old Saxon English, and led young people to believe that the uncouth, the high-sounding, the long words of many syllables borrowed from foreign languages, and sentences ever so involved and long, are some of the essentials of elegance. It would be well to recollect that as "brevity is the soul of wit," so strength and elegance may ever be joined with the simplest words and the shortest sentences. Instead of going to such uncouth slang for models, it would be wiser to consult, in this respect as to style, the Book of Books, the pages of the "Spectator," the volumes of the "Gardener's Magazine," especially after the great Loudon was united to Mrs. Loudon, for seeing how massive strength and vigour may be

combined with the terse, simple, old Saxon, with its short words and short sentences. And once more on this subject, it is wise not to be too demonstrative, not to be always imitating the draper who hangs all his most valued goods in the windows. The humble student is not likely to do this. The educated scholar has a considerable temptation to transgress, and therefore, when writing homely English, he will let us know his superiority by introducing Latin here, Greek there, and French and even German ever and anon. Can anything be more stilted, unmannerly, ungentlemanly? We may feel our ignorance and our inferiority enough, but we may not choose to have them thus unceremoniously thrust upon us. If a writer feels he cannot express his meaning except in Latin or French, let him write for those who understand such languages. If he condescends to write in homely English and for English readers, let him keep to the English tongue. We consider it sufficiently copious to express every idea that is worth expressing. Such interlarding of other languages is a great disappointment to the humble English scholar. Intelligent people pass it by with the remark—"Ah, poor fellow! he must ring a bell to tell people how clever he is." He is only looked up to as something marvellous by that small and decreasing portion of our population who resemble the old woman, who valued the abilities and the learning of a clergyman in proportion as she thoroughly failed to understand him.—R. FISH.

(To be continued.)

STRAWBERRY-GROWING.

I HAVE been much interested by the article of your correspondent "H. C. K.," and I remember having seen his plan some years ago and then intended to try it, but owing to a change of residence and other circumstances it escaped my recollection. I am, however, somewhat at a loss to know whether I am to take his instructions literally or not. He says, "Place round each plant a heap of half-rotted stable-manure, so as to stand 8 or 9 inches high after being firmly pressed down with the hands; and the ring thus pressed down should extend about 10 inches all round—plants 20 inches at least apart."

It occurs to me that the quantity of manure is excessive, and that the result would be that the plants would be at the bottom of a hole 9 inches deep, and excluded from sun and air except from the top of the hole. If the plants are placed 20 inches apart every way, it follows that the entire plot will be covered with manure.

Your correspondent does not say whether he finds it needful to renew the mulching every year or not. I shall be obliged by his reply.

I yesterday assisted in gathering some of the fruit from three rows of Crimson Queen Strawberry grown about half a mile from Darlington by an amateur gardener, and it may interest you to hear fourteen of them weighed 1 lb. (avoirdupois weight) exactly. It is a magnificent fruit in size, colour, and flavour.—A. ATKINSON.

OPEN-AIR FORCING OF EARLY CELERY.

THE following method has been successfully carried out by me when early Celery was required. I may add that I have had good blanched Celery fit for any table by the middle of June. I put fresh manure in the bottom of the trench, and made it pretty firm to the thickness of 10 inches, adding 4 inches more of good rotten manure on the top. I then left it until the next morning, when I gave the manure a good soaking of urine saved for the purpose. I left it for two more days; and, it being warm weather, it fermented as I calculated it would, and produced a very genial heat. I then covered it over with about 4 inches of soil made quite fine, and left it until the next morning, when I gave it a thorough soaking of liquid made from rotten dung and urine, and left it all night. In the morning it was of a temperature suitable for giving anything a start, and kept on for about ten days, which was quite sufficient for my purpose. I put in the plants the same night, and just sprinkled them overhead with water. The next morning I gave them a good drenching with tepid water. I planted

them a foot apart every way, kept within 3 inches of the bed all round, so that it held three-score plants. I did not use a dibber, but made a hole with one hand, and was careful to spread the roots well. I may say the plants did not droop in the least, but started into growth at once at a most surprising speed. My worthy employer seeing the effect gave me great credit, for Celery had never succeeded in the garden before. I kept the plants in most vigorous growth for about five weeks before commencing to blanch.

I have omitted to state that after planting I covered all the bed amongst the plants with fresh horse-droppings from the stable, which assisted in keeping the bed warm and the dry air from the roots, and it acted as a stimulant when watering upon it. I kept a tub near to the bed filled with a mixture of fresh horse-droppings and a fair proportion of urine, and applied this every other evening not sparingly, but always watering overhead with clear tepid water, occasionally putting a little soda in the water, and having the water-tub fully exposed to the sun. I only blanch with 6 inches of soil, which I add to the plants at twice, finished-off with brown paper and other material; frequently watering and keeping it moist about them. Chickweed or any vegetable rubbish of that substance does well to finish-off blanching.

I should like it to be understood that the above practice is only applicable for procuring early Celery.—WM. LEDGER, *Gardener*.

P.S.—The Celery I am now writing about measured in height 3 feet 6 inches, and appeared to be the thickness of a man's leg. When prepared for the table each head weighed 2 lbs.

THE ALEXANDRA PARK FLOWER AND FRUIT SHOW.

IT says something for the taste of us good English folk, that we do not consider a grand ceremonial complete unless a flower show be either a portion of it or looms at no great distance off. What would an Oxford Commemoration or a Cambridge commencement be without the flower show, where fair flowers and fairer maidens enchant the eyes of soft undergraduates and old time-honoured dons? what the Crystal Palace but for those wonderful gatherings of floricultural skill, to be present at which so many procure their season tickets? Would the Royal Horticultural Society stand six months, with all its royal patronage, but for its flower shows? And so, wisely did the projectors of this new people's park determine to inaugurate the opening of it with a grand flower and fruit show.

The park itself is another proof of the taste for the beautiful in nature which exists amongst us. Situated at so short a distance from London, it would hardly be believed by strangers to it what rare sylvan beauty, and exquisite undulating ground and extensive prospects it affords.

The art of the landscape-gardener will have little need to be called into requisition, as the ground is so beautifully laid out; and when the buildings shall have been erected, it will be to the inhabitants of the north side of London what the Crystal Palace is to those on the south. Nor do I think that it will interfere with the success of the older establishment. Tastes like these increase by being ministered to, and, like a new line of railway, open out fresh resources, while they increase the facilities of spending a pleasurable day in lieu of the stifling atmosphere of a public-house, or the questionable enjoyments of other places of resort. I believe, too, that many things manifest a desire to carry out this institution effectively. If I am rightly informed, no attempt will be made to open it on the Lord's day; the whole management of the police arrangements will be entrusted to that well-tried body the corps of commissioners; and amusements of a low character will not be admitted. The superintendence of the garden has been placed under the able management of Mr. Mackenzie, lately of Brighton; and as it is the intention of the Company to erect a portion of the International building in the grounds, some reminiscence of that famous place of resort will be perpetuated; and as the palace of Sydenham sprang like a phoenix from the ruins of the building of 1851, the Alexandra Park will owe its origin in a good measure to that of 1862.

Thus the ironwork and glass will be utilised for a new

Crystal Palace to be erected on the highest portion of the grounds, from whence a view rivalling in extent and beauty that from Sydenham is obtained—a view extending over the counties of Hertford and Essex, down the valley of the Thames, to Erith, &c., and away into Kent, while London is hid from view by the hills of Highgate and Hampstead. The richly wooded and park-like character of the foreground reminds one very much of that around Beckenham and Penge. Of the estate itself, which contains 480 acres, at least 250 will be retained for the purposes of the Company, and the remainder will be let off for villa residences. A large portion of it will be left in its present condition, as it is Mr. Mackenzie's opinion that landscape-gardening can add but little to the beauty of its sylvan glades, which will afford a fine scope for picnic parties to roam about at leisure as well as if they were a hundred miles from London. The trees around the Grove House are very beautiful; one walk, called Dr. Johnson's Walk, formed of large and wide-spreading Oaks, will, we venture to predict, be a favourite stroll, where

"Lovers' vows seem soft in every whispered word."

There are also a magnificent Chestnut tree, a fine Copper Beech, and other trees equally beautiful. I hope sincerely that the ruthless hand of the improver will leave these untouched. As I looked round on the capabilities of the place the thought came across me, To whom is Mr. Mackenzie likely to look for counsel in this matter? and I could not but wish that Mr. Marnock had a voice in the matter. He made so much of the capabilities of the Botanic Gardens in the Park, and many of his other efforts at landscape-gardening in the more natural style have been so successful, that he would be quite at home here. Water is not wanting; and although there is but a small portion of it at present, I do not doubt that it will be greatly enlarged and made as attractive as possible.

The Company, who only completed the purchase of the ground on the 24th of last month, determined to open it with all the *célat* possible, and so arranged to have, if possible, a grand flower show and an archery fête. It was a bold venture, for all depended on the state of the weather. Had the wretchedness of Tuesday and Wednesday continued, the whole affair would, both literally and metaphorically, have had a damper put upon it. As it was, with brilliant sunshine and fanned by a genial westerly breeze, it was a most decided success; and when to this is added that the flower show was one of the best—some placed it as the best—that have been held this season, that most of our great exhibitors were there, that a most liberal schedule induced competition which made it difficult to determine often which were the best, and that not one bad collection of any kind was staged, your readers may form some notion of the treat that it was to those who visited the grounds.

The amount of produce sent completely took Mr. Mackenzie by surprise, so that tent after tent had to be put up until four were more than filled. The large one contained as magnificent a collection of stove and greenhouse plants as have ever been massed together in July. The second contained a fine collection of fruit, the cut flowers, and table decorations. The third was filled with Roses and Fuchsias, and the fourth with fruit trees in pots; and in most of the classes it has rarely been my lot to record such splendid collections. The Roses exhibited by Mr. Keynes have never been equalled, as far as my knowledge goes, his collection of 100 blooms being a most marvellous lot. It is something even in a box of 48's to say that there is not a bad bloom in it; but when in a box of 100 one could not positively fix on an indifferent bloom, it may be well conceived what a rich collection it was. His box of 48's was hardly inferior to this; while the Messrs. Paul exhibited some very fine collections. Mr. Fraser's was also good. Amongst amateurs the contention was not sharp, there being but three exhibitors.

Mr. Turner exhibited some extraordinary blooms of Carnations and Picotees, as fine as I ever recollect to have seen them; but, as it would be impossible for me at this late period of the week to do justice to the florists' flowers, I must reserve my fuller notes of them for next week. I cannot, however, omit noticing the beautiful dinner-table decorations exhibited by Mr. James Cutbush, of Highgate, in which evidently a lady's exquisite taste had been called

into request—no little birds, bits of coral, shells, or fish disfigured the exquisite refinement of the arrangement of fruits and flowers. Some beautiful hanging-baskets were also contributed, and imparted great beauty and variety to the Exhibition.—D., Deal.

STOVE AND GREENHOUSE PLANTS.—The total amount offered for these was large—no less than £148, and the display made was proportionably good; the principal contributors being Mr. Williams, of Holloway, Messrs. A. Henderson & Co., Fraser, and Lee.

In the different collections were several excellent examples of *Allamanda Schottii* and *grandiflora*, two beautiful *Dipladenias crassinoda* and splendens, *Stephanotis floribunda*, *Rondeletia speciosa*, *Erica Parmentieri rosea*, in fine bloom; the lovely *Pteroma elegans*, *Vincas*, *Ixoras*, *Kalosanths*, and other plants usually exhibited, with the addition in the mixed collections of numerous handsome specimens of fine-foliaged plants.

In collections of twelve, the first prize was taken by Mr. Gilbert, gardener to E. McMurdo, Esq., Hastings; the second by Mr. Wheeler, gardener to A. Philpott, Esq., Stamford Hill.

In the Nurserymen's Class for eight, Messrs. J. & J. Fraser had first prize for a collection, in which were *Ixora javanica* and its variety *floribunda* in fine condition; a splendid *Kalosanthe* called *Phoenix*, and *Vinca ocellata*. Mr. Rhodes was second.

For mixed collections of flowering and ornamental-foliaged plants, the highest prizes were awarded to Messrs. A. Henderson & Co. and Mr. Williams, both of whom contributed extensive collections. In that of Messrs. Henderson were *Ixoras*, *Allamandas*, *Vincas*, *Clerodendron fallax*, and *Gnaphalium eximium*, a showy *Everlasting* with orange flowers when fully expanded; and for foliage several fine *Caladiums*, *Alocasia macrorrhiza variegata*, *Jacaranda filicifolia*, *Alocasia Lowii*, *Maranta fasciata* and *zebrina*, and *Cissus porphyrophyllus*, but not looking so handsome in its old as in a younger state. Mr. Williams had *Dendrobium formosum giganteum*, *Miltonia spectabilis*, *Cattleya crispa*, *Kalosanthes coccinea*, a very large *Latania borbonica*, and *Gleichenia speluncæ* and *heciostophylla*, both very fine. Messrs. Lee had a handsome *Alocasia metallica*, *Cordylina indivisa*, *Dracæna ferrea*, *Cissus discolor*, *Ixora coccinea*, several small *Heaths*, and some other plants.

HEATHS.—The show of these was good, though many of the specimens were not equal in size to those seen at previous exhibitions. Among the most effective were *Parmentieri rosea*, *ampullacea major*, *ventricosa* *Bothwelliana*, *vestita coccinea*, *Aitoniana Turnbulli*, *metulæflora bicolor*, and *tricolor Wilsoni*. Messrs. Jackson & Son and Mr. Rhodes, of Sydenham, were respectively first and second in the Nurserymen's Class, and Messrs. Fraser third. Mr. Gilbert had first and Mr. Wheeler second prizes in the Amateurs' Class of eight; and in the Open Class for six kinds Messrs. Lee were first with a collection in which was a splendid plant of the showy scarlet *vestita coccinea*, *ampullacea scotica*, and *Aitoniana Turnbulli*. Mr. Rhodes was second; Mr. Smith, of Norwood Grove, third.

ORCHIDS were not numerous. The best in the Amateurs' Class for fifteen came from Mr. Young, gardener to W. Stone, Esq., Leigh Park, Havant, who had some excellent *Cattleyas* and *Oncidiums*, *Phalenopsis grandiflora*, and several *Ærides* and *Saccolabiums*. By far the best collection, however, was that shown in the Nurserymen's Class by Mr. Williams, of Holloway, who had *Cattleya crispa* and *Leopoldi*, several fine *Oncidiums*, including *Lanceanum*; *Stanhopea maculata*, *Trichopilia tortilis*, *Saccolabium Blumei* major, and several fine *Ærides*. Messrs. Jackson & Son had *Stanhopea oculata*, *Oncidium Lanceanum*, and some good *Cattleyas*.

FERNS AND FINE-FOLIAGED PLANTS.—The latter, besides being shown in the mixed collections, had also classes in which they could be exhibited by themselves. They consisted of the kinds usually seen, many of the specimens, however, being very handsome. We particularly noticed *Alocasia metallica* with magnificent leaves, coming from Messrs. Lee and Mr. Williams, between whose plants it would have been difficult to have said which was the best. *Alocasia Lowii* was also sent by both these exhibitors. A fine specimen of *Cordylina*

indivisa came from Messrs. Lee, and a magnificent *Gleichenia hecistophylla* from Mr. Williams, who had also *Dion edule*, and *Latania borbonica*, both of which were large and handsome specimens. Messrs. Lee had first prize; Mr. Williams the second; and Messrs. A. Henderson, who had also an excellent collection, were third. In the Amateurs' Class for ten, Mr. Taylor, gardener to J. Yates, Esq., Highgate, had first prize for some large specimens, among which were good specimens of *Encephalartos latifrons*, *Dion edule*, *Theophrasta imperialis*, &c. Mr. Young, of Highgate, was second; and Mr. Donald, Leyton, third. The most remarkable Ferns were the tree Ferns from Mr. Williams, consisting of *Dicksonia antarctica*, *Cyathea serrata*, *Smithii* and *excelsa*, and *Alsophila australis*, all of which were of great size. For these Mr. Williams received a first prize, and he gained a similar award in the Class for twelve exotic species. His collection contained large specimens of *Cyathea Smithii*, *Cibotium Schiedeii*, and *Gleichenias dichotoma*, *semivestita*, *flabellata*, and *spelmæ*. Mr. Woolley, of Cheshunt, was second; Messrs. A. Henderson third. In the Amateurs' Class the best collection was that of Mr. Young, of Highgate.

MISCELLANEOUS.—Some good pans of Lycopods came from Mr. Young, of Highgate; *Lonicera aureo-reticulata* from Mr. Shenton, of Hendon; and from Mr. Williams an interesting collection of new and rare plants, most of which have been noticed at previous shows. Among them was the fine variety of *Disa grandiflora* called *superba*, *Dendrobium Parishii*, *Epidendrum prismatocarpum*, *Cupania pin-daiba*, *Aloeasia Lowii*, *Pogonanthra reflexa*, *Cheilanthes Borsigiana*, &c.

FRUIT.

There was an excellent show of fruit, particularly of Grapes and Peaches, most of the exhibitions being very good.

In collections of eight dishes, Mr. Turner, of Slough, had the first prize for Black Hamburg Grapes, Queen Pine, Golden Perfection Melon, Moorpark Apricots, Royal George Peaches, Bigarreau Cherries, and Violette Hâtive Nectarines. Mr. A. Henderson, gardener to the Duke of Sutherland at Trentham, was second with West's St. Peter's, Frankenthal, and Black Hamburg Grapes, a Ripley Queen Pine, two Melons, Royal George Peaches, Elruge, and Violette Hâtive Nectarines, Moorpark Apricots, Brown Turkey Figs, Denyer's Victoria and Green Gage Plums, and Morello Cherries. A second prize was also awarded to Mr. Young, of Havant; and Mr. Carr, of Byfleet Lodge, Surrey, was third.

PINES were generally good. For four, two of a sort, second, and fourth prizes were awarded to Mr. Hannan, gardener to R. T. Crawshaw, Esq., for Queen and Ripley Queen; third to Mr. Henderson, of Trentham; and fourth to Mr. Penny, Regent's Park, for Moscow Queen. The most remarkable exhibition among Pines, however, was a Queen stated to be of the enormous weight of 7 lbs. 2 ozs., and which was also a handsome-shaped fruit. It came from Mr. Hall, gardener to the Earl of Scarborough, Sandback Park, and, of course, received the highest prize. Mr. Carr who was second, had also a finely-grown fruit of large size, its weight being 5 lbs. 13 ozs.; and a similar award was made to Mr. Kaile.

GRAPES.—The best of these came from Mr. Meredith, of Garston, who was first for three dishes, first for a single dish of Black Hamburgs, first for a single dish of Any other variety with splendid bunches of Trentham Black, also for a box of Black Hamburgs weighing 20½ lbs., the berries in every case being large and well-ripened, and the bunches of Hamburgs large and compact. The second prize for Black Hamburgs was taken by Mr. Wallis, gardener to J. Dixon, Esq., Astle Hall, Congleton, who had also similar awards for a good box of the same variety, and three bunches of Black Prince in the Any variety Class, one of them being fine, though far from equal to those exhibited by Mr. Hill at the Royal Botanic and Kensington Shows. Muscats as usual were generally unripe. The best came from Mr. Turner, of Slough, his bunches being far in advance of all the rest in point of ripeness, and the berries were of good size. Mr. Smith, of Norwood Grove was second, and Mr. Embury third.

PEACHES AND NECTARINES formed a good show. In two dishes of each Mr. Turner was first with Violette Hâtive and Elruge Nectarines, and Royal George under the name of Millet's Mignonne, and Violette Hâtive Peaches. Mr. Monro,

of Rabley, Barnet, was second; Mr. Hill third. In two dishes of Peaches Mr. Beech, gardener to F. Alcock, Esq., Kingswood, was first with Grosse Mignonne; Mr. Dawson, gardener to Earl Cowper, Panshanger, second with Violette Hâtive and Early Grosse Mignonne. Mr. Turner had a most excellent dish of Royal George, also Violette Hâtive, receiving the third prize.

MISCELLANEOUS.—Moorpark Apricots from Mr. Kaile and Mr. Knight, Rowfant, had first and second prizes; Messrs. Lane & Son received a first prize for Rivers' Early Favourite Plum grown in pots; Mr. Turner and Messrs. Lane first and second prizes respectively for Bigarreau Cherries; and Mr. Turner first for some excellent Circassian Cherries. In Green-fleshed Melons the best was a white-fleshed Hybrid Cashmere from Mr. Rutland, gardener to Captain Peploe, Garnstone Castle, Hereford; the second best, Golden Perfection from Mr. Monk, Tottenham; and in the Scarlet-fleshed class Mr. Stanley was first with Scarlet Gem. Messrs. Lee had a first, and Messrs. Lane a second prize for Vines in pots.

THE PROPOSED GARDENERS' FRIENDLY SOCIETY.

I READ of your amazement at the apathy of gardeners to what concerns them so intimately, so vitally, with something like surprise, but also, I must confess it, with something of shame as to my share in that painful perplexity. I have been purposing writing to you ever since your very clever correspondent "G. A." propounded, and you so thoroughly perfected, the scheme; but I fear that my evil genius, Procrastination, has again stepped in and done me, and in a certain sense the whole profession, this injury. To those who could handle the subject perfectly and discuss it in all its bearings, throwing light on its most minute ramifications, there is a fruitful field open; and I long to hear Mr. Fish give his ideas upon it, knowing as I do that he will see in it, and through it, and all round it, and tell us what he sees with simple perspicuity.

I, for one, unhesitatingly give in my most cordial and thankful approval of the scheme. It is just the very thing that I have been wanting for some time, ever since I was married particularly. I should be delighted if it could be carried out. I had been debating with myself whether or not to enter the Gardeners' Benevolent Society, but the funds of that Society (albeit it is a most noble institution), are too precarious for my approval. I should be sorry to be left, or that my wife and children should be left, to the tendermercies of subscribers' votes. The machinery of canvassing is too cumbrous, too laborious, too expensive, too uncertain in its issues. You may spend a small fortune in canvassing subscribers' votes and then lose your election.—*St. A., Notts.*

I FULLY agree with "AN IRISH SUBSCRIBER," and Mr. F. Chitty, that gardeners are strangely backward in the efforts they make for the furtherance of their good as a class; and I deeply regret the but-too-palpable inertness to which they have seemingly given themselves up. I cannot find a justifiable excuse for this; nor can I even conscientiously endorse that put forth by Mr. Chitty—namely, a want of greater and more immediate communication between individual members of the class. I would not dispute the probability, that were it possible for them to come within more immediate communication the one with the other, that this and many other kindred subjects would be effectively ventilated, and the views of each at such gatherings would be the more readily communicated the one to the other; but every gardener, however isolated, can sift a subject, and settle what are its merits or demerits. To bring this into more immediate bearing upon the proposed Society, I ask what there really is therein to call for numerous minor discussions? Already we have in a plain readable form the preliminaries, the very rules of a society, placed before us. Our proved friends, the Conductors of this Journal, have offered these pages for a free discussion of the subject—a subject which, no one will dispute, is of deep and lasting interest to us as a body.

I have watched these pages weekly for either adherents or dissentients; yet have been much disappointed in my wishes as to either. It should be well understood that where a question is asked to be answered by the general gardening community, it is not for the staff-writers of this Journal to give a response at first. Either way may be of use; but I did expect (the least indeed that could have been expected), that very many strenuous advocates for so great a desideratum would have been found amongst those who do not as a rule resort to so rational an occupation as that of giving publicity to their opinions or practices generally.

This Society is a proposal which should bring the most prosperous of the class to its aid; for these are the individuals who should do all in their power to forward the advancement of our class and calling.

I would earnestly ask my fellow gardeners, if they are favourable to the establishment of such a Society, to act at once—not for each to wait with, it may be, the thought of seeing what others may do in the matter.

Let me also hope that the Editors have not come to the conclusion that there is no success; and also let me hope that a sufficient number will at once send in their adhesion to the rules generally, thereby justifying a commencement in so great a requirement. I am not only ready, but anxious, at the earliest moment to subscribe my mite towards the expenses ever attendant upon the preliminaries of such an undertaking.—W. EARLEY, *Digswell*.

THE FROST OF JULY 19TH.

[In addition to our notice of this frost, inserted at page 57, we have the following communication.]

WILL you oblige me by stating whether the frost of yesterday morning (19th) was general or only partial? as the tops of my Fluke Potatoes (at Waltham Cross) were all frosted, and are now thoroughly blackened. Also will you say if the Bougainvillea will do in a greenhouse, as I can do nothing with it in my stove-house; and what treatment do you recommend?—AN ORIGINAL SUBSCRIBER.

[We had a slight white frost on the morning of the 19th at Luton, but it left little or no traces behind it. The Bougainvillea will do best in a stove in summer with heat below the roots, abundance of water given to it, and the shoots kept near the glass. In autumn less water should be given to the roots, but heat kept on and a dry atmosphere. In winter keep drier still; and increase heat and moisture gradually in spring. We think a greenhouse will be too cold for it, but time will try. It requires heath soil and loam to grow in, and abundant drainage. We fear your plant must be sickly.—R. FISH.]

DEATH OF MR. FRASER.—It is with feelings of sincere regret that we announce the demise of Mr. Fraser, the celebrated landscape-gardener, which took place at his residence, 25, Westland Row, Dublin, on the night of the 12th inst., after but a few days' illness. Mr. Fraser has been amongst the most successful of Irish landscape-gardeners and land-improvers, and there are but few residences of our nobility and gentry in Ireland where traces of his sound judgment, eminent skill, and classic purity of taste may not be found; and his abilities were so greatly appreciated, that his practice had considerably extended through England and Scotland for several years past. The extensive improvements carried on at Curraghmore during the late Marquis of Waterford's lifetime; at Castle Martyr, the seat of the Earl of Shannon; at Adare, that of the Earl of Dumraven, and hundreds of other fine old seats; and the new creations of Gowran, Lord Clifden's; Castle Oliver, the Misses Gascoynes'; and Saunders Court, the Earl of Arran's, remain lasting monuments of his great abilities. His literary attainments were of a high order, and his handbook for Ireland and traveller's map, which have gone through several editions, are in the highest estimation with tourists, commercial men, and travellers of every grade, as the surest and best guide to all who wish to see Ireland thoroughly and profitably. As a personal friend many will mourn his loss.—(*Irish Farmers' Gazette*.)

ROYAL HORTICULTURAL SOCIETY.

JULY 21st, 1863.

FLORAL COMMITTEE.—Mr. Salter, Hammersmith, exhibited two Pompon Dahlias, *Deutsche Bellis* and *Goutte d'Or*, their chief recommendation being a dwarf habit. These specimens were grown in pots, and it was decided that their merits would be better tested when grown in the open ground; also, *Pelargonium Aglae*, with pink flowers having a white centre, very similar to *Rose Queen*.

Mr. Bull, Chelsea, sent three *Caladiums*, *Pallisi*, *regalis*, and *Cannaertii*—the plants were very small, and it was requested they might be seen again; also, *Boussonetia papyrifera foliis variegatis*.

Mr. Watson, St. Albans, again sent *Calceolaria Bijou*, with chocolate crimson flowers. This plant received a second-class certificate at the second great Exhibition, June 17th; but from its improved character and promising usefulness as a bedding variety, it was on this occasion awarded a first-class certificate.

Mr. J. Holland, Spring Grove, exhibited two seedling *Petunias*, one semi-double named *Circle*, the other *Hollandii*, a small, striped, convolvulus-shaped flower.

Mr. Thompson, of Ipswich, exhibited *Helipterum Sandfordii*, an annual from Western Australia of the Everlasting section, with small bright yellow flowers in dense bunches. As a bedding plant it was considered desirable, and was awarded a first-class certificate. Seeds of this annual were sent to England ten years ago by Mr. Drummond, but till the present time the plant has been little known in our gardens.

Mr. John Boff, Balls Pond, sent *Verbena Firefly*, with variegated foliage—a coarse worthless variety; Mr. Wainwright, Kettering, a seedling *Pink*, *Prince of Wales*, of the *Anne Boleyn* class, but very thin and small; Mr. J. Perkins, Northampton, cut flowers of a seedling *Verbena*, *Charmer*, deep mulberry with a peculiarly marked centre.

Mr. Turner, Slough, had four seedling *Picotees*, all of them of excellent quality. They were *Lucy* (Taylor), a pure white ground, light rose-edged flower—first-class certificate; *Col. Clerk* (Norman), light purple-edged, good form; *Miss Sewell* (Kirtland), fine, light rose-edged flower; and *Miss Williams* (Norman), a light rose-edged flower.

Messrs. Downie, Laird, & Laing, sent a beautiful seedling *Hollyhock*, *Alexander Shearer*, of first-rate form, full and circular flower, dark crimson red, for which a first-class certificate was awarded; also a collection of twenty-four *Hollyhocks*, which for their excellent qualities received a special certificate. Among them we particularly noticed the following—*In Memoriam*, Mr. Chater, *George Keith*, *Perfection*, *Illuminator*, *Miss Nightingale*, *Sambo*, *Empress Eugénie*, *Lady Daeres*, *Lord Loughborough*, *Primrose Gem*, *Excelsior*, and *Purple Prince*.

Mr. Parsons sent six seedling *Achimenes*, of which one named *Moorii* was a pleasing variety, with soft rosy salmon flowers and a fringed or ciliated margin: it received a second-class certificate. The remainder were good varieties, but not distinct from others in cultivation.

Mr. William Paul exhibited cut specimens of a seedling *Hybrid Perpetual Rose* *Princess of Wales*, bright carmine rose, which was much admired, and when seen again under more favourable circumstances will doubtless receive a high award. After the Meeting a box was sent by Messrs. Barr and Sugden, containing cut specimens of an old and well-known plant—*Gloxinia tubiflora*, remarkable for its long white-tubed flowers. These specimens had been just received from Nice, and were damaged by their long journey.

FRUIT COMMITTEE.—Mr. Whiting in the chair. Prizes were offered at this meeting for the best dishes of Peaches and Nectarines respectively, and for the best collection of the newer varieties of Strawberries; but there were no exhibitions in these classes.

Mr. Whiting exhibited fruit of *Jefferson Plum* in competition for the best dish of Plums, and received the first prize. Mr. Terry, gardener to L. Ames, Esq., The Hyde, St. Alban's, received the first prize for the best collection of Currants. There were *Raby Castle*, *Red Dutch*, *Red Champagne*, *Old Black*, *Black Naples*, and *White Dutch*, all of which were very fine examples of the varieties.

Mr. Perkins, nurseryman, Northampton, sent a seedling Strawberry named Earl Spencer, which possesses great merit. It is of good size, conical shape, and regular form. The colour is pale scarlet, like British Queen; the flesh is solid, and has a fine pine flavour. The Committee recommended this variety as being of great excellence, and well worthy of cultivation. Messrs. Carstairs & Sons, of Edinburgh, also sent a seedling Strawberry; but it was not considered superior to Keens' Seedling, to which it bears a close resemblance. The dish of Keens' sent along with the Seedling was not, however, considered as very creditable to the cultivation of that variety in the neighbourhood of Edinburgh.

A fine collection of Currants was sent from the garden at Chiswick, and Mr. Terry exhibited a fine dish of Tomatoes.

ECHINOCACTUS RHODOPHTHALMUS (RED-EYED ECHINOCACTUS).

Nat. ord., Cactaceae. Linn., Icosandria Monogynia.

A GREENHOUSE succulent plant of sub-columnar form, 6 inches or more high, longitudinally divided into eight or nine deep furrows, with obtuse ridges formed by transverse lines into lobes or tubercles, each tubercle bearing a cluster of about nine strong, straight, spreading spines, about an inch in length, the central one longest and standing forward. The flowers—from the top of the plant—are large, handsome, the petals linear-spatulate, rose-coloured, a dark red stain at the base forming a radiating circle around the staminal column. From Mexico: San Luis Potosi. Introduced about 1847, by F. Staines, Esq. Flowers in summer.

Mr. Smith, Curator of Kew Gardens, says that Cactae are almost indifferent as to the kind of soil they are grown in, provided it is not retentive of moisture, and that the present very pretty species will thrive in a mixture of light loam and leaf mould, containing a small quantity of lime-rubbish nodules, the latter being for the purpose of keeping the mould from becoming close and compact, a condition not suitable to the soft and tender roots of the plant. If cultivated in a pot, it must be well drained; the pot being nearly half filled with broken potsherds, and the upper layer so placed as to cover the interstices, in order to prevent the mould from mixing with the drainage. During winter,

Mexican Cactae do not require much artificial heat: several species are, indeed, known to bear with impunity a few degrees of frost. Where they can be cultivated by themselves, we recommend that the plants and atmosphere of the house should be kept in a dry state during winter, artificial heat being given only during a long continuance of damp cold weather or in severe frost; but at no time during winter need the temperature of the house exceed 50° at night. In sunny days in spring the house should be kept close, in order that the plants may receive the full benefit of the heat of the sun's rays. As the summer heat increases air should be admitted, and occasionally the plants should be freely watered, and in hot weather daily syringed overhead.—(*Botanical Magazine*, t. 4486.)

FORCING STRAWBERRIES.

HAVING been tolerably successful in the forcing of Strawberries, and ascribing a good deal of that success to the treatment they receive previous to forcing, I send you the mode adopted—the more readily, perhaps, because it differs so materially from the advice given a week or two since by your able and practical correspondent Mr. Fish. The plan is an old one, perhaps, and is adopted elsewhere possibly, but I have not met with it in my travels. It is this: Those plants that fruit in April I allow to bear runners, say six to each pot. When done fruiting they are placed in a cold pit to harden-off; they are afterwards planted out in a well-prepared border, care being taken not to injure the runners at any time when moving them. By adopting this mode the plants are ready to go into fruiting-pots by the 1st of July, three weeks earlier, I presume, than by the plan recommended by Mr. Fish, which I am sure that gentleman will think is an object gained.

The forcing part is quite a different affair; but if you think proper I will send you some account of a plan that secures a crop of large fruit and excellent flavour. I may mention that the plants are not allowed to remain layered in 60's more than three weeks, or a month at most, previous to their final shift into 32's.—J. Gross, *Gardener to D. R. Scratton, Esq., Priory, Prittlewell, Essex.*

ON THE WINTER EFFECTS OF COLOURED WOODS IN LANDSCAPE GARDENING.

I do not know that it has ever occurred to others, how much may be done towards rendering a garden cheerful in winter, by employing shrubs with coloured woods in the arrangement of the planting. Downing certainly makes no allusion to it in his "Landscape Gardening." I have often thought of it, and have intended to try something of the kind on my grounds so as to form some idea of the practical effect, but have always forgotten it when the proper planting time came about. It occurred to me again recently through happening to see a Golden-barked Willow and a small nursery of Silver Maple trees side by side. The red and gold together, against the background of snow, that laid on the side hill on which the trees were growing, had quite a pretty effect, though of course you will say better matches of colour could be made than this accident afforded.

How would a mass look having, say, for the outside a thick set of the Red Dogwood (*Cornus sanguinea*), then a circle of the green shoots of the Ash-leaved Negundo, then the red scarlet of the Silver Maple, and the Gold Willow behind, all kept twiggy and dense by pruning?

Perhaps some of your taste-loving readers will communicate their views and experience. No doubt many would be interested—certainly the writer of this.—C., *New York.*

[The idea is novel and has merit in it. The White-barked Dogwood (*Cornus alba*), has the brightest-coloured wood, and is probably the one our correspondent refers to. *Cornus sanguinea* has dull brown wood.—Ed. *American Gardeners' Monthly.*]

GRAPES AT GARSTON VINEYARD.—There is such a house of Black Grapes at the Garston Vineyard as is seldom seen, and, I may venture to say, not to be surpassed if equalled in England. I am referring to the house from which Mr.

Meredith cut the Grapes which so astonished the visitors at the Royal Horticultural Society's Garden on July 1st, and for which he obtained the first prize. Perhaps some of your readers are not aware that Garston is six miles distant from Liverpool. Omnibuses leave Castle Street every half-hour for Garston, and excursion trains are running from

nearly all parts of England to Liverpool, affording gardeners a good opportunity of visiting the above place. The other vineries, Pine-pits, &c., are very extensive, and contain very fine shows of Grapes in later stages, but the one house alone is worth a journey of a hundred miles to see.—W. L. K.

PLAN OF ONE OF THE FLOWER GARDENS AT PENTILIC CASTLE, CORNWALL.

1, 8, 16, 23, Tom Thumb Geranium.
2, 7, 17, 22, Purple Petunia.
10, 11, 14, 15, Saponaria.
12, 13, Heliotrope.

9, 24, Calceolaria floribunda (which has been out all the winter).
5, 4, 18, 21, Geranium Flower of the Day.
3, 6, 19, 20, Geranium Manglessii.

In grass border.—All the small circles Calceolaria Aurea floribunda.
25, 22, 30, 37, 46, 51, 44, 39, Ivy-leaved Geranium.
27, 43, 24, 41, Lobelia.

HARDY DECIDUOUS TREES.

FINE old trees connect the present age with the many that have gone before it, and remain, as it were, a living chronicle of the many revolutions of society that have occurred during their growth. It is, therefore, with no ordinary interest that we ought to look on such trees, venerable alike in appearance and in the associations they call up, and we ought to regard their loss as that of old friends when accident or misfortune deprives us of them. Fortunately of late years the laudable desire to retain those emblems of the past has greatly increased, as well as the love of other objects of antiquity. There is no reason why an old work of nature should not find the same favour as does an old work of art—a remnant of masonry is certainly not more an object of just interest than an aged Oak. The latter, doubtless, bears the mark of time, and if in a state of decay is looked on with feelings of interest; the other is regarded with regret that the barbarous usage of a former generation should have left us so little of a pile we gaze on with admiration. But old trees and old buildings are not unusually associated together, and nothing can keep company with greater harmony than those two relics of former times; not all the wealth of the present day can give that grandeur to a building which is often afforded

by the old trees by which another structure of less pretension is surrounded.

How many of the abodes of our nobility are not less remarkable for the venerable appearance of the trees in their parks than for their dwellings. Who has not often heard of, and admired too, the stately Oaks, the sombre Beeches, and magnificent Elms, with which a park is studded? and while the mind is admiring their beauties as the visitor approaches the abode of the owner, a feeling of respect is engendered for bygone generations who have left such legacies to the present one.

Fine old trees also give an importance to a place which wealth cannot command; for however cleverly constructed the machines may be which the various inventors have patented for the purpose of transplanting large trees, fine old ones are beyond their power, and if such trees were even moveable, they are not often articles on sale.

With no ordinary interest, then, ought we to regard fine old trees; and any of our readers who happen to know of remarkable ones for size, would confer a favour on the reading community by forwarding their dimensions. Trees of unusual size are scattered far and wide, and they often enough flourish unknown almost to any but to the limited

residents of the locality. Unfortunately we are all too prone to pass by such things, only noticing in a vague manner that the tree "is a remarkably fine one." We take a walk round it, and a look-up to its top, and then with some exclamation about its great size, too often bestow upon it no more thought. Candour compels me to say that such has been too often all the notice I have taken of such trees; but I often meet with objects of remarkable growth in places not having the reputation of being the best adapted for such things, and I will adopt a different course for the future, for I think a little notice of such trees now and then will be of service to the community at large. The little that I am able to report on the matter is all from personal knowledge except where otherwise stated; but, unfortunately, the information is but meagre, nevertheless it may be the means of inducing others to report more interesting objects in other localities.

Commencing with the acknowledged king of our forests, THE OAK, I think I have seen at least four individual trees each asserting that dignified title. A very fine tree of this kind, which to all appearance seemed likely to require some two or three centuries yet to bring it to perfection, so healthy and vigorous it seemed to be, was at Panshanger, the princely seat of Earl Cowper, in Herts. I have quite forgotten the extent of ground its umbrageous top hangs over, and a finer or healthier tree it would be difficult to find. Some very fine Oaks also adorn the noble park at Dunham Massey, the seat of the Earl of Stamford and Warrington, in Cheshire. These, however, to the best of my recollection, were more remarkable for the fine timber they contained than for any remarkable extent of top; but there were plenty of tall, fine, bold trees having a circumference of 15 feet and upwards at 5 feet from the ground; and a very large park was very heavily wooded with such trees. The soil seemed sandy; and if dry, the fall of rain in the neighbourhood, being greater than in most places, supplied the moisture, but I do not think it was deficient of that element. I was told there was a king of the forest here, but I had not the opportunity of seeing it; still the great number of fine trees astonished me. Next to the Oaks the Beeches were numerous and good, and other kinds were not wanting. Further northwards there is some tolerably good Oak timber in the best districts of the county of Durham; and one at Gilbeide, on the property of the late Earl of Strathmore, but I believe now Mr. Bowes', contained something like eleven loads of timber some thirty years ago. This tree was growing in a wood and was near the bottom of a slope, the soil a sort of hazel loam rather plentifully mixed with stones. It was a much less healthy tree than the one at Panshanger, but might, perhaps, contain more timber, and its top was not remarkable; in fact, some of its limbs had been broken off by high winds. I believe there are several places in Yorkshire remarkable for fine trees, but I have not visited them, and, therefore, leave their description to other hands; and Scotland has also its monarchs of the forests. An Oak at Netherwitton, in Northumberland, was once pointed out to me as good, and certainly it seemed of great size, but I forgot the particulars; and many districts, doubtless, would have had their fine trees at the present day had not the temptation to cut them in time gone by been so great as to tell seriously against their preservation. Even parks of established antiquity have at some period or other of their history been denuded of their ornaments by some needy or avaricious proprietor; but remarkable Oaks are of frequent occurrence, less perhaps so than Beech: the latter being a less valuable commodity in the market, there was not that inducement to cut for sale. Some fine Oak trees adorn the park of Knowle, Kent, but those of Cobham in the same county are evidently of a more recent date. Every one has heard of the fine Oaks of Windsor Park, and many other places may be cited as containing good specimens.

Next in importance to the Oak as a park tree is THE BEECH, and in habit of growth it is scarcely less beautiful—in fact, it is not unlikely that if we could divest ourselves of the poetic feeling attached to the Oak as being connected with our national greatness, it is not unlikely but the Beech would be regarded as the more noble in its growth. The habits of the trees are not so much unlike: a wide expanded top, with a bole more or less branched as the position of the tree may have determined. But my purpose is not

to make the comparison, but to describe some remarkable trees, asking at the same time for other contributors to record their observations as well. In the first place, I may say that I regret very much not availing myself of the chance I once had of seeing the Burnham Beeches in Buckinghamshire, which are reported to be such fine specimens of the ancient Beech. There are, however, some fine trees in other counties. The fine park of Knowle, above alluded to, contains some fine avenues of Beech, as well as groups, and single trees innumerable; some are of remarkable size, but the bulk are still in what may be called excellent timber-condition. Several stages beyond this state, however, have the Beeches advanced in the park of Sir Percival Dyke at Lullingstone in the same county; some that I measured being little short of 30 feet in circumference at 4 feet from the ground; and by their appearance they looked as if they would outlive several generations yet of the human race. A dry hilly situation with chalk underneath was their abode. Beeches are also common in many places, not the least remarkable being some places in Bedfordshire and the adjoining counties.

THE ELM is a greater favourite with the farmer than with the poet, not that the farmer likes its presence any further than that the district where it grows spontaneously indicates good land. I believe the vale of the Thames contains some of the best Elm trees in the kingdom, and I have seen very good specimens in Oxfordshire. A good, rich, and deep soil suits this tree best, and on such a soil its growth is, perhaps, quicker than that of any tree we have, unless it be the Horse Chestnut. Elms are, however, not so long-lived trees as the Oak, Yew, Beech, and others; for when decay sets in they much sooner succumb to it. We seldom see a hollow Elm, for the decay at the bottom eventually increases so as to weaken the collar, which gives way before a high wind, and down the tree comes. Unlike those trees mentioned, it does not appear that the root makes any effort to sustain the declining condition of the trunk by surrounding the remaining sound wood with bark, and a fresh accession of layers. Instead of this the Elm root often decays also, or if left to a state of nature some rising suckers abstract all the nourishment. Elms furnish more suckers than most other trees, and to this, doubtless, may be attributed the shorter period of their existence as compared with these. Elms make an excellent avenue, and even as individual trees they look well; the expanded top and large sturdy limbs, striking boldly out in all directions, give the tree a noble appearance in autumn and winter. Its roots travel a long way for food, and quickly appropriate to themselves a heap of compost, mould, a flower-bed, or anything tempting that comes in their way, in which case they rob their neighbours. A corn field is not unlikely to suffer from this cause. But the noble proportions of the tree entitle it to respect; for I should think that no other forest tree we have arrives at the size the Elm will do in a suitable soil. One in the grounds here (Linton), which seems perfectly sound, and likely to increase in size for many years to come, is upwards of 16 feet in circumference at 5 feet from the ground, and apparently loses very little in thickness at 20 feet up. There are several others of about the same dimensions. A good rich soil, not too shallow, suits the Elm; and its presence, like that of Nettles, often indicates a generous soil.

J. ROBSON.

(To be continued.)

FLORA OF THE ROMAN CLASSICS.

(Continued from Vol. III., page 703.)

THE ESCULUS OR ÆSCULUS.

THERE is much uncertainty among modern authors as to the tree mentioned under this name by the Roman writers. After gathering together what these have stated concerning it, we shall be better able to decide what tree known to us agrees with the characteristics they ascribe to the Esculus.

Palladius says, "The Esculus is suitable for building and for Vine-props. Quercus timber should not be mixed with that of Esculus, for that of the Quercus if wetted will warp when it begins to dry, causing chinks in the floor, but that of the Esculus continues without such a blemish."—(*De Re Rustica*, i., 9, and xii., 15.)

Virgil says, "Some trees are produced from sown seed,

as the lofty Chestnut; the *Esculus*, which is the largest that flourishes in the groves of Jove; and the *Quercus*, reputed oracular by the Greeks."—(*Georg.*, ii., 14-16.)

Pliny observes, "The *Quercus* and the *Robur* (probably our *Quercus racemosa* and *Q. robur*), we see growing everywhere, but with the *Esculus* it is otherwise." "The acorn, properly so called, is borne by the *Robur*, *Quercus*, *Esculus*, *Cerrus*, *Ilex*, and *Suber*." "The *Esculus* is dedicated to Jove." "It ripens its acorns in the autumn." "It is impatient of a wet soil."—(*Nat. Hist.*, xii., 1.—xvi., 6, and 26 and 41.)

Horace refers to the hardness of its wood when he says that the obduracy of Lyce was "not more yielding than the unpliant *Esculus*;" and he alludes (*Odes*, i., 22), to "the spacious *Esculus* woods" of *Daunia*, a portion of the Neapolitan territory bordering on the Adriatic.

In the *Georgic* already quoted (lines 291-2), Virgil says, "*Esculus* tends towards Tartarus with its root as far as with its head towards the ethereal regions." Now, in our present inquiry, it is very significant that in the 4th *Æneid* Virgil makes the same descriptive observation, repeating every word, when speaking of *Quercus*.

Ovid characterises the *Esculus* as having "lofty leafy branches."—(*Metam.*, viii., 410—x., 91.)

Pliny also states that for Vine-props it was cut every three years, that it is produced from an acorn, that the props are least of any liable to decay, and that cutting it freely makes it produce shoots more abundantly.—(*Nat. Hist.*, xvii., 20.) The best and largest acorns, he also says, were borne by the *Quercus*, and the next by the *Esculus*.—(*Ibid.*, xvi., 228.) The civic crown was first formed of sprays of the *Ilignus*, but subsequently of the *Esculus*, sacred to Jove.—(*Ibid.*, xvi., 4.)

These scattered details lead us to the conclusion evidently entertained by the Bauhins, Parkinson, Ray, and Linnaeus, that the *Esculus* of the classic writers is the Oak now known as the Italian or Prickly-cupped Oak, *Quercus esculus* of some botanists, but probably identical with *Q. pubescens*. Its leaves are numerous, are about 3 inches long, and 1½ inch wide, on footstalks nearly 1 inch long, with shining surfaces paler beneath than above, finely veined, and disposed alternately on the sprays. They are well suited to forming the honorary head-wreath bestowed by the Romans. The acorn when full grown is about an inch long, and its scaly cup about one-third of that length. It is sweet and eatable, so much so as to be brought to table roasted both by Spaniards and Italians in country districts. There was a tree of this species in the Horticultural Society's Chiswick garden which Loudon records as having borne crops of acorns. We have inquired about this tree; but, like many others, it seems to have been recklessly cut down by Mr. McEwen.

Few people are aware that acorn is only an abbreviation of ac-corn, or oak-corn, a name justified by the prevalent use of some kinds of this mast in remote ages. Even now the acorns of *Quercus ballota* are sold both in an uncooked and roasted state in the markets of Algiers, and are a common article of food with the Moors.

Quercus esculus is not so abundant in Italy as some of the other species, but is found perhaps more frequently in the countries bordering on the Adriatic. It is lofty, though not one of the loftiest of the Oaks, averaging 40 feet when full grown. The soil in which it flourishes best is a well-drained, rich, sandy loam. It still bears the name of *Eschia* and *Esculo* (according to Parkinson), in Italy.

M. Tenore says that there is a very fine variety of the *Quercus robur* found in the woods throughout the kingdom of Naples, distinguished by its large leaves, and which is there called the *Chêne Castagnara* (Chestnut Oak). It was formerly known under the name of the *Quercus latifolia* (Broad-leaved Oak). This has been considered by some the *Esculus* of Pliny and other Latin writers; but Tenore expresses himself as certain that that is the *Quercus esculus* of Linnaeus.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE July Meeting of the Entomological Society, held on the 6th inst., with the President in the chair, was more than ordinarily interesting. A considerable number of donations

to the library received since the last Meeting from Vienna, Munich, Stockholm, Königsberg, France, &c., were laid upon the table, the Society being at length resolved to concentrate its forces on its library and publications. A notice to this effect, and that it had been resolved to dispose of the remaining portion of the Society's collections, including the British insects, was given by the Secretary, it having been found impracticable to form even a tolerably perfect indigenous collection, whilst the expenses attending its preservation and exhibition were more than equivalent to the benefit resulting from its retention.

On the motion of Mr. Dunning, it was resolved that the thanks of the Society be given to W. W. Saunders, Esq., F.R.S., Treasurer of the Royal Horticultural Society, &c., for his liberal entertainment of the members at Reigate on the 22nd ult., when an interesting entomological excursion in that charming locality, planned by Mr. Saunders, was joined in by a large number of the members, and some interesting captures made during the day were exhibited by several of the members present at the July Meeting.

Mr. Stevens exhibited a case of rare insects collected in South Australia by Mr. George French Angas.

Specimens of the beautiful *Carabus auratus*, long esteemed a doubtful British species, were exhibited by Mr. Brewer, recently taken on the coast of Kent between Dover and Hythe. Unlike the other British species of the genus, they are found running about during the day. It was, however, stated that the late Mr. Walton had imported and turned a number of French specimens of the species loose twenty years ago between Dover and Deal, whence it was possible that the recently-captured specimens might be the descendants of some of these imported individuals.

Mr. Stainton exhibited specimens of *Elachista apicipunctella*, one of the *Tineidæ*, bred from larvæ found in the leaves of a *Festuca*, although ordinarily they mine the leaves of *Holcus lanatus*.

Professor Westwood, in reference to the curious hermaphrodite Honey Bees exhibited at the June Meeting by the President, stated that a long account has been published in the "Transactions" of the newly-established Entomological Society of Switzerland of a hive of Bees which for several years had produced a number of such monstrous individuals, a fact which appeared to militate against the theory of parthenogenesis. He also exhibited drawings which he had recently made at Dresden of the larvæ and pupæ of the anomalous genus *Coronis* contained in the fine collection of Dr. Kaden. He also gave a description of the preparatory states of the equally curious genus *Castnia*, of which the larva resembles that of the longicorn Beetles, whilst the pupa is very similar to that of *Cossus*, with rows of reflexed hooks on the dorsal segments. He also exhibited specimens of *Graellaria rufipennella*, a small Moth, the larvæ of which during the past month of May had been very injurious to the foliage of the Walnut in Southern Tyrol, the trees having the appearance of having been scorched with fire. This fact was the more remarkable (being quite unknown to the Vienna entomologists), as the ordinary food of the larvæ are the leaves of the Plane tree. He also exhibited specimens of *Eucheira socialis* in the perfect state. This Butterfly had hitherto been known only by the description which he had published thirty years ago of the family cocoon formed by the larvæ within which the chrysalids are suspended in society. He also exhibited specimens of the two sexes of *Papilio Castor* and *Pollux*, which had been erroneously regarded as sexes of one species, and also produced photographic representations of a remarkable hermaphrodite specimen, proving the correctness of his separation of the two insects.

Mr. Stainton gave an account of the discovery of the larvæ of *Micropteryx fastuosella* in Nut leaves on Marlborough chalk downs. He also stated that he had been called up to award the entomological prize at Marlborough College for the best collection of Lepidoptera, and that there were seven candidates for the prize.

Mr. F. Moore exhibited some Galls on Elm leaves, caused by the punctures of a species of *Aphis*; and Mr. Dunning, a white silky secretion found deposited over a quantity of Chicory, probably by the larvæ of some species of *Tinea*.

Mr. Burchall exhibited several specimens of *Dianthæa capsophila*, and the Rev. Mr. Marshall brought a number of

the rare *Platyrhinus latirostris* for distribution among the members.

A paper was read by Mr. Pascoe containing descriptions of sixty new species of Australian longicorn Coleoptera, and another by Mr. F. Walker, containing descriptions of new Spellingidae and Egeridae in the British Museum collection.

Professor Westwood moved, and Mr. Stainton seconded the following resolution, which after considerable discussion was carried unanimously:—"Considering the state of the entomological collection of the British Museum, and the vast accessions still unarranged which it has recently received, rendering it the most valuable collection in the world, but which requires the services of more than one person skilled in the science of entomology for its due classification.

"Resolved, that the nomination in the stead of Mr. Adam White, of a person previously employed as a transcriber in the printed-book department of the Museum, entirely unknown as an entomologist, cannot but prove a great detriment to the progress of the classification of the collection, as it virtually is a waste of the public money. This is still the more objectionable, as several good and competent entomologists were candidates for the situation."

It was also resolved that a copy of this resolution should be forwarded to the Trustees of the Museum.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Clear away haulm-stumps and the refuse of crops as soon as they are over, and if the ground is not required, dig it over, to remain till wanted. At this season, however, there is seldom ground to spare; for it should be remembered that the supply for several months of the next winter and spring will depend in a great measure on the diligence now made use of in planting-out as large a supply of those kinds of vegetables most likely to be in demand as can possibly be found room for. *Broccoli*, any that are now planted in dry weather to have their roots dipped in puddle consisting of soot, earth, and water, and after planting to be again watered. The Cape and Grange's intended for use in the autumn to be also watered; but the spring roots when they have got hold will not require it. *Cabbages*, there should now be no delay in getting in the main sowings for spring supply. Bailey's is an excellent variety, to which may be added the Nonpareil, Vanack, East Ham, and the London Market. The first sowings to be pricked-out into nursery-beds: it is to be preferred to leaving them in the seed-bed, as it makes them stocky and well-rooted, and, consequently, better able to withstand the severity of the winter. *Carrots*, a few of the Horn may be sown to stand the winter; but another sowing should also be made towards the end of August. *Celery*, abundance of water to be given to that newly planted, and to the earliest crop copious applications of liquid manure with a small portion of salt dissolved in it. *Lettuce*, make a sowing of Cos and Cabbage for late use. *Onions*, the tops of the early crops to be laid down if they are inclined to be too rank, going over the bed or rows with a wooden-headed rake, and pressing the tops down sufficiently to check farther growth. *Turnips*, another sowing to be made; if the weather is dry the ground to be watered after the seed is sown, and covered with mats or any other temporary shading. Vacant ground, or that which can be cleared of early crops, may be planted with Winter Greens, &c., first giving it a good dressing of manure and a deep digging. When ground is limited the Potatoes and other crops soon coming off may be interlined with Broccoli, Winter Greens, &c., and, further to economise space, a quantity may be planted at a foot apart, to wait for ground as it comes in by the removal of other crops, when the whole may be again planted at proper distances, or every other row and each alternate plant of the remainder may be removed to vacant ground.

FLOWER GARDEN.

The late-planted flower-beds to be looked over, and the plants either pegged-down or staked-up as their habits may require, or as may best suit the taste of the cultivator. Those which are planted against basket-edgings, or against framework which is used to intersect beds, to have their shoots neatly arranged and tied-in. All decayed flower-

stems and leaves to be removed; all plants done flowering to be cut down, and annuals that have ceased to be gay to be pulled up, and their places filled from the reserve stock. Proceed with the laying of Glove and other border Carnations. Mule and Anne Boleyn Pinks done in the same way will make strong healthy plants before winter. All seed-vessels which may have been left on the Roses during the flowering season to be cut-off. Autumn-blooming sorts will be much strengthened and bloom better during the next three months if partially pruned and well soaked with manure water. The ill effects of boisterous weather will be experienced in the flower garden if prompt and effective precautions be not employed to guard against its action—staking, tying, &c., should be assiduously followed up; Dahlias, Hollyhocks, Pelargoniums, Petunias, and Calceolarias may be specially named as susceptible of injury from wind and rain. Rose-budding to be actively proceeded with. Fork the ground slightly around Dahlias, and mulch the surface with very rotten manure; water plentifully two or three evenings in the week when the weather is dry; the laterals to be well staked-out, and every means to be used to entrap earwigs. Ranunculuses and Anemones should all be out of the ground; if showery weather set in they will immediately emit roots, when their removal would be injurious.

FRUIT GARDEN.

The summer pruning and nailing-in of the current year's wood will require following up; the late rains have caused an increased growth of midsummer wood, which may be allowed to remain for a short time till the growth becomes less active, before stopping or cutting-back is resorted to. Top or remove the rampant suckers of Raspberries, and attend to the Strawberry planting.

GREENHOUSE AND CONSERVATORY.

Remove the flowers of *Aphelaxis* and *Helichrysums*, cutting the flower-stems close in to the old wood, then set them in a cool shady place; when they begin to grow, such as require it, to be repotted. *Kalosanthes*, the flowers of which are getting shabby, to be cut-in below the blooming branches. Attention to be paid to late-growing plants in the borders of the conservatory; for while in active growth they require a good deal of water. Adequate precautions to be taken to protect the tender greenhouse plants placed temporarily out of doors from the effects of the frequently-recurring storms of wind and rain. The pots to be closely examined lest the plants suffer from defective drainage or the presence of worms. Cut-down *Pelargoniums*; pot-off cuttings directly the roots are formed; repot those plants previously headed-down as soon as they begin to break. Shift and sow *Cinerarias* and *Calceolarias*. The stock of pot Roses to be looked over, useless wood and decayed blossoms removed, and the plants shifted if they need it. The Teas are admirably adapted for pot-culture; a little heath soil to be mixed with the compost, which should be very rich in decomposed nightsoil or rotten dung, chopped turf of a rich loam, with a sprinkling of pounded charcoal or sparkling sand.

STOVE.

Watch closely for insects. *Ixoras* done blooming to be cut-in, and started gently. The Orchids suspended in baskets or on blocks will require a liberal supply of moisture. All blocks will need frequent, though light, syringings, and let as much fire heat be kept up as will allow of a quiet circulation of air.

PITS AND FRAMES.

Propagation of stock for next season must soon be commenced and carried on with expedition, so as to secure strong well-established plants before winter, and without the necessity of keeping them so close or warm as to induce weakly and watery growth. Begin with such as are found to be the most tedious to propagate, and prepare for winter.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Much the same as last week. Hoed the ground between crops, weeds or no weeds, for the easiest way to keep clean is

not to allow weeds to grow an inch in height. Sowed fresh patches of Endive, Lettuce, Turnips, Radishes, Onions, and Spinach. The Spinach will be the last we will sow until we sow for the winter in a fortnight. Sowed also Matchless Cabbage for the main early crop, a few Red Cabbage, and a pinch of Cauliflower, in case it should be needed. Were pretty well done up for water; but Tuesday and Wednesday brought us delightful rains, that set us planting Coleworts, Broccolis, Borecoles, Brussels Sprouts, &c., and Celery, that formerly planted having been well watered from the heavens. With warm weather after the rains everything will grow amazingly. Corn will fill the bushel, and Turnips will soon protect themselves.

Pricked-out Parsley in beds where there were missed places, and sowed a little more to go under protection. Regulated Tomatoes, Capsicums, and Cucumbers, letting the latter get a good watering from the rain. We had been obliged to shade those in frames to keep the sun from them, as we dreaded to give them any water. Now we shall be all right again for some time. Spawned a bit more of a Mushroom-bed, and covered with fresh droppings and a little sheep-dung. The first bed in the shed is doing wonders, though made of rubbish chiefly. Peas and Beans, and Cauliflowers will now be all right. With all our care we could not prevent the latter heading prematurely, and the dry heat caused the heads to come more open than we like. For several hot days the butterflies were in myriads; but as some boys caught several hundreds, we hope to escape a glut of caterpillars among the vegetables. Raised early Potatoes before the rain.

FRUIT GARDEN.

Removed nets from Cherries and Strawberries that were gathered, and put them on Gooseberries, &c. This rain will give soft food to the birds, and we shall not be quite so much eaten up. For a week in the dry weather the bird-fanciers might have had a treat. A clap of the hands, or the snap of a gun, would cause some half a hundred of thrushes and blackbirds to darken the air, singing out defiance to you as they rose and just cleared the wall. We fancied they would not meddle with a border of Elton Strawberries planted as undergrowth in a late border of Gooseberries, because the aforesaid Strawberries are rather sour; but though the Gooseberries are untouched, they have pretty well cleared the Strawberries in a day. When once they tasted them it was all up—they were busy at them by three in the morning. We notice to-day that they have begun to look after slugs and worms below Laurels, &c., and we wish them every success in their beneficial change of occupation.

Gathered the bulk of Black Currants, and especially Raspberries, as otherwise the birds would have had the whole. There will be a good supply after the rain. Regulated fruit trees, fastened Fig trees out of doors, watered those in house, watered Vine-border before the rain came, and gave a little fire heat to late Grapes, to prevent them being chilled by the change in the weather. Other matters much in the way of routine of previous weeks. Before watering the Vine-border, as the crops are heavy, threw a bushel of soot, and more than a bushel of superphosphate of lime over the border. The rain coming soon after has left no appearance of the manures on the surface. Would have given a few pounds of the nitrate of soda, if we could have obtained it conveniently, just to give a fillip to the foliage in the later houses.

ORNAMENTAL DEPARTMENT.

The rain has changed the appearance of everything. The lawn had been knifed several times to decapitate a stray daisy or plantain; but it was beginning to get such a rusty appearance that we were afraid to make it worse by passing a mowing machine lightly over it. We never knew a lawn need so little doing to it for the last month. Now it will get as green as leeks again, and will require our cropping care after being well rolled. The same as to beds. Calceolarias that were beginning to hang their heads, notwithstanding our efforts at mulching and surface-stirring, are now holding up their masses of flower boldly, and the rain has as yet come so mildly that scarcely a bloom has been washed off. We hardly expect that any sorts of flowers will

again suffer so much from drought this season; and if the autumn be fine, from all we have heard and the little we have seen, flower-beds will be very attractive this season. The *Amaranthus melancholicus* does no great things with us out of doors, but it is a nice plant for a cool plant-house. Some amateur would make a sensation by filling his little greenhouse with fine-foliaged plants alone. After this the whole of the fine-foliaged Begonias will stand well in a greenhouse, especially if the position is a little close and shady.

Kept striking Pinks, Cloves, Carnations, Antirrhinums, &c. Now is a good time to lay Carnations and Picotees. They do not strike well as cuttings or pipings unless they have a little bottom heat. Secured Hollyhocks, Phloxes, strong herbaceous plants, Dahlias, and other flowers needing support, and stuck a pin in the top of a good number of stakes to prevent birds sitting on them and sending their droppings over the foliage. Robins and linnets are rather the worst birds for doing this, and they are not easily dislodged from their favourite perch. Some birds will take the hint if you have even the head of the pin uppermost, but others will wriggle round the pin unless you place the point upwards, or, at least, take off the head, and in either case the little things are apt to be injured, which we would avoid doing if we could.

Remove a portion of the foliage from some of the Dahlias, or rather shortened a few of the leaves in order to give more relief to the flower-buds, and throw additional strength into them. A little disleafing of extra-luxuriant plants will secure extra abundance of bloom. Went round some edgings of *Nasturtium* for a similar purpose. The stems of these are so succulent that they will bloom all the better from not having too much foliage. We have some good wreaths of some kinds; but others are as yet rather unequal, owing to a little neglect in the warm weather. These plants generally grow so strong that we did not think of watering them, and some plants are three times the size of others. The large ones will fill all the allotted space if we only give them time enough; but, to our eye, one great beauty in flower-groups is their regularity, from whatever point viewed. Regulated most of the Geranium-beds before the rain came, and will finish these and others as soon as the soil is a little dry; and in doing this and keeping edgings distinct, much more time is required than a passing visitor would imagine. We find even now it is necessary to insert a plant now and then, though very few have died this season, hot and dry though it has been.

In most cases all our brushwood sticks, or stakes, are now concealed. Our walks, which had not been broken for years, were firm and smooth on the surface; but the surface in many places was of a dull colour, and to remedy it we threw a slight sprinkling of fine-sifted salt all over them, and then a slight sprinkling of fine siftings of gravel, which, when swept, would give a fresh appearance to the walks; after that the passing of a roller, as we did to-day after the rain, would secure as firm and smooth a surface as before. Now these simple operations are the result of experience. Supposing we put the salt on, and a sudden rain came, it would be washed away, and do no good in clearing off the dark patches. Supposing the salt remained and was absorbed gradually by the dews, the walk would be apt to be damp and cloggy in moist weather. Now the throwing the fine siftings over the salt—and we only had very little altogether—prevents the salt being washed away, and then it is gradually absorbed, whilst the fresh surfacing secures a dry, clear, firm surface to walk upon. We should not like to use salt for cleaning walks after next month, as we should expect them to be damp all the winter.

Potted Scarlet and other Geraniums, Pelargoniums, &c. Sowed Primulas and Cinerarias. Pricked-off first sowings of Cinerarias. Potted Chinese Primulas, *Cassia corymbosa*, Feathered Cockscombs, *Browallias*, *Gesneras*, &c.; and fresh set conservatory, taking away most of the Pelargoniums, and replacing with others, Fuchsias, and a bank of Begonias, &c., in a shady place. Regulated climbers, and gave them extra watering, as *Bignonias* and *Passifloras*, &c., were beginning to feel the drought. Went on with watering, potting, and cutting-making as opportunity presented itself, and found it a relief to have a dripping day to get pots and pans properly washed.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ASPARGUS PLANTS DYING (Gallier).—Some of the plants dying, whilst those which live produce very fine heads, and the soil being tenacious, lead to the conclusion that there is stagnant moisture in the beds. We would put in drain-tiles, 3 feet below the surface, on each side of the beds, and if you can have no other outfall sink a boghead at one end of the beds, and let the drain-pipes empty themselves into it. You cannot do better than remove the surface soil as you propose, but instead of sifted ashes use a mixture of equal proportions of sandy loam and thoroughly-decayed stable-manure. Add this when you dress the beds in the autumn, but drain at once, and apply salt at any time. Your *Lapageria rosea* requires a large and constant supply of water.

GRAPES SHRIVELLING (A Constant Subscriber).—Give the roots of the Vines a good soaking once a week with tepid water. Previously to beginning to do so remove the surface soil down to the roots, and in its place put a mixture of equal parts light loam and decayed stable-manure. Give more air day and night. We know of no better mode of preventing the roots of Raspberries rambling except digging a trench down the side of the plantation and ramming it full of stones.

GRAPES SHANKING (One in a Fir).—Remove the surface soil down to the first-occurring roots. Refill with some rich compost, and water freely with tepid water. Give more air, and keep the house at least 5° cooler both during the day and the night.

WORK DESCRIBING PLANTS (Casarea).—London's Encyclopedia of Plants nearly coincides with what you parti. uralise. It describes them, has woodcuts of some of each genus, and though not alphabetically arranged there is an index.

VINE LEAVES SPOTTED AND GRAPES PARTIALLY SHRIVELLER (Nesvio).—There is most probably a deficient root-action. Remove the soil down to the first layer of roots, replace it with a compost of equal parts light loam and well-decayed stable-manure, and then water copiously with tepid water.

CLIANTHUS DAMIERI (Clapton) will be obliged by "JUVENIS," whose remarks were published in page 25, stating when he sowed the seed of this plant.

PLANTING A VINERY (S. H. S.).—About five Vines will be enough for your vinery, 21 feet long. If planted inside at back, the floor should not be covered, so as to intercept the sun's rays. If planted inside in front, and the roots allowed to go into an outside border, the plants will always be protected as respects their stems; but in planting in this way the inside border should always be higher than the outside border. If the border outside is new good loamy soil, and not exhausted, it may grow Vines well enough with the help of a little rotten dung, lime rubbish, and some eight or ten bushels of broken bones incorporated with it. As you have 2 feet of wall up to the wall-plate now, we would not take out much soil if we made a fresh border entirely; but we would take off 1 foot, if we even used part of it again, ram and concrete the bottom, dig a drain in front 2 feet deeper than the concreted bottom, put drains across the concrete, and place a foot of rubble over it, which would leave about 20 inches of soil up to the wall-plate. The best soil is brown mellow loam from the top spit of a pasture, mixed with brick rubbish and manured according to the richness or poverty of the soil. Bones are the most lasting manure. Part of the border next the house may only be made at first. The Vines will do as well if they have a fresh piece added every year.

GRAPES DISEASED (J. M. Miller).—The berries are "shanked"—that is, their stalks are gangrened and dead. We believe that the best treatment you can adopt is that which we have recommended to another correspondent whose Grapes are shrivelled.

GRAPES MILDEWED (N. Gloucester).—The Grapes are very severely mildewed, which is "the Vine disease." You have let it have its course too long unchecked. Dust the whole of the bunches and leaves with flowers of sulphur. Brush the stems and branches with a paint made of sulphur, clay, and water, and sprinkle flowers of sulphur also over the surface of the bunches. When the sulphur has been on the Grapes for four or five days syringe them freely; and when the berries have dried again repeat the sulphuring. Continue this routine until the white mildew (*Oidium Tuckeri*), is no longer discernible on any of the berries.

HEATING A GEE HOUSE (T. P.).—There can be no question as to your securing more heat by running the flue along the back of your greenhouse. In fact, for such a small place as 22 feet by 9, we would be satisfied with a good flue. We have no fault to find, however, with the adjunct of the boiler; but we would advise you to have three or four-inch pipes instead of two-inch pipes. As you purpose to divide the house, it would be as well if you could cause the water to circulate in the first division without going into the second, except when you wanted, which could be easily done, and then with the flue, hottest next the furnace, and the hot water in addition, one division might be very hot, whilst the other was comparatively cool. If you did not do this you could regulate heat by air.

ERYTHROLUNA, &c. (W. W.).—*Erythroluna conspiciua*, or Mexican Thistle, still bears that name; but *Renealmia nutans* is now called *Alpina nutans*. The latter we know is in cultivation, but we have no information relative to the Mexican Thistle.

CUCUMBER (C. S.).—The double Cucumber you sent is not usual, but we have seen it before. It is produced by two ovaries coming in very close contact when young and continuing their growth together.

MAIDEN-HAIR FERN (J. I. C., Dublin).—It is not necessary to repot it every year. As it is in a 16-inch pot or pan and you do not wish it to have a larger tenement, cut away a portion all round, remove a little of the surface soil, and fill up all the vacancy thus made with fresh soil. If you do this annually it may remain in the 16-inch pan for years.

CULTURE OF BORONIAS (A Subscriber).—We fear "watered occasionally" is the cause of your *Boronias* dying. They will not endure stagnant moisture, neither will they endure dryness, and more especially if the pot is pretty full of roots and exposed to the fierce sun we have lately had. The soil you used, peat and charcoal, is all right. The temperature in winter should be not below 45°, or from that to 50°. Let good drainage be secured, and some broken pots might be mixed with the charcoal in the soil. When forming buds and flowering a good supply of soft water would be needed. When done flowering, and the flowering-stems pruned off, keep the plants dryish but not dry for a fortnight, just slightly syringing overhead morning and evening. After that give a little more water, and place the plants in a mild forcing-house, or in a close shady place in the greenhouse to encourage fresh growth. As growth advances give more air and light by degrees, until by August the plants stand in the full sun. Then, however, the pot should either be protected from the full force of the sun's rays, or be set in a larger pot with a little moss inserted in the opening at the top. We fear that dryness and sun together have killed your plants.

ORCHIDS (An Orchid-lover).—You are right in your intention to visit the nurseries you name, as well as Kew. There are no Orchids at Chiswick, and you can only obtain admission to the Kensington Gore Garden by a Fellow's transferable ticket, or in company with a Fellow. When in London, if you furnish us with your address, we may be able to aid you.

GRAPES (Tom Brown).—Your Grapes are the Dutch Hamburgh, and there is no doubt but that they will become sweet and eatable; but have you not too heavy a crop? Possibly that is the cause of their not colouring and acquiring flavour more rapidly.

HOUSE-SEWAGE (Z. Y. Godalming).—Such a sized garden and so copped needs scarcely any manure. Some of the "slops" might be given to the Rhubarb once a week undiluted; and some to the fruit trees that seem in want of vigour. You cannot employ all the sewage.

BOOK ON VINE-CULTURE (P. B.).—Hoare "On the Vine" is entirely confined to out-door culture.

NAMES OF INSECTS (J. R. Jessop).—The Lime-tree leaves had been infested with the plant louse, *Appis Tilia*, which had been devoured by the larvæ of the two-spotted lady bird, *Coccinella bipunctata*, of which the pupæ were affixed to the under sides of the leaves. These pupæ, being attached by the end of the body to the leaf, on being disturbed hit themselves up like a large-hummer as you notice.—W. W.

NAMES OF FRUIT, &c. (Constant Reader, Dublin).—1, Your Plum is the Myrobalan or Cherry Plum, only not for tarts; 2, We have never tried, or known any one else besides yourself who has tried, DuRoi's powders. We should be glad if some of our readers would give us their experience of them; 3, You will find very good instructions for the cultivation of *Lapageria rosea* in No. 33 of our New Series; 4, *Rhododendrons* and *Kalmias* that have done flowering in-doors should now be turned out if they have completed their new growth, and placed in a moderately shady place.

NAMES OF PLANTS (Sarah).—Your Oaks are—1, *Quercus alba pinnatifida*; 2, *Q. alba pinnatifida*; 3, *Q. coccinea*; 4, *Q. alba pinnatifida*; 5, *Q. aquatica*. (*C. R. C.*)—*Fagus sylvatica* heterophylla. It is a variety of the common Beech, and the branch at the top is a return to the normal form. (*C. Burwell*.)—*Cestrum aurantiacum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WORCESTERSHIRE POULTRY SHOW.

JULY 21ST—24TH.

"*fidelis civitas*,"—and a "faithful city" it was to the Stewarts—has during the past week been a town of banners and rejoicings. The usual accompaniments of dancing-booths, beer-houses, concerts, wild beasts, and rifle-galleries, followed the Royal Agricultural Society of England. Poultry is an elevating pursuit; and although the Royal Agricultural quarrelled with it, and gave it the cold shoulder some years ago, yet it took high ground. It forgave; and on the principle of doing as it would be done by, it took its station on the threshold, and added its attractions to the many others. It, doubtless, sent many to the showyard, and had to thank it for some visitors.

The place was well chosen. On a slight acclivity immediately facing the Agricultural show-yard, the Committee had pitched a large square tent. Square commodious pens were fixed on every side; and with the exception of Ducks, Geese, and Turkeys, which were of necessity on the ground, all pens were in single tier. Four rows running from side to side filled the centre, making up the number of nearly three hundred pens, exclusive of Pigeons, and affording ample space for visitors between the rows. The spot was well chosen, and the efforts of the Committee met with a reward in the pleasing coup d'œil afforded by the Show on entering.

Game headed the list. It is not wonderful it should be so. Worcestershire has for many years been in the front

with this breed, and some of the birds shown were worthy of the old reputation, while none of them were inferior. The names of the successful would be a guarantee for the merits of the birds. Among others, the Brown Reds of Mr. Fletcher were very meritorious. We preferred them to the first-prize Black Reds belonging to the same gentleman. Mr. Dyas and Captain Wetherall also deserve mention. The Duckwings were excellent, especially the old birds; and among the Open class for Game, it is worthy of note as a rare occurrence, that the Blacks took all the prizes.

Dorkings, both chickens and adults, left nothing to desire. They brought out some of our best exhibitors, among them Mr. Wakefield, who took four prizes. He was, however, beaten in *chickens* by the Rev. J. E. Newton. The Revs. J. G. A. Baker, and Martin Amphlett, with Messrs. Dain and Tudman, made the prize-taking difficult.

The *Spanish* were good.

There was an excellent show of *Cochins*, of every age and colour, but we were sorry to see many of the *chickens* with vulture hocks. Captain Heaton's Grouse pen is a very good one, the cock a marvellous bird. It is needless to say Mr. Stretch's Bufts were capital, and Mr. Earle may think himself a meritorious exhibitor when he takes precedence of the Rev. G. Gilbert and Messrs. Bishop and Dawson. Mr. Tudman held a good position, as he always does, in Grouse *Cochins*, but was hard run in *chickens* by one of our "cosmopolitan" exhibitors, Mr. Wakefield, who was second. The Whites were far above the average, and we were pleased to notice the absence of green legs among chickens, and white ones among adults.

Golden-pencilled *Hamburghs* were lamentably weak. Silvers made amends. A spur was given by the offer of a handsome porcelain vase by Mr. Kerr. Mr. Walsh took first in both classes. Of course, he gained the vase. He was also second for *chickens*. All the rest were taken by Mr. Marshall. Golden-spangles were strong in adults, weaker in *chickens*. Silvers reversed—they were strong in *chickens*, weaker in adults; but there were meritorious birds in all. Mr. Hyde's birds were very good, also Messrs. Fielding's and Beldon's. Mr. Dixon ran them closely. We cannot forbear a remark here. In all *Hamburgh* classes, the white deaf-ear is imperative, but it should be dead white as frosted silver, and the size of a fourpenny-piece—sixpence should be the limit. It may then be understood that the deaf-ear in a *Hamburgh* as large and pendent as the ear-lobe of a Spanish cock must be a defect.

We can speak in unqualified praise of the *Polands*. Gold, Silver, and Black were alike good; but it is not necessary *Poland* fowls should follow human fashions. It is common in the present day for men to part (we believe that is the correct term) their hair down or across the head *de gustibus*, &c., but it is not desirable in a *Poland* hen; a pen of Blacks with white tops was shown wherein the tops of the hens were fairly parted down the middle. The top-knot of a *Polish* hen should resemble a cauliflower, not only in shape but in closeness. It should be as large as possible, but it should be close.

Crève Coeurs were weak in numbers, but not in quality. The honours gained by Messrs. Pigeon and Wakefield would not have been diminished, in all probability, if the competition had been greater.

The Various class gave another proof of the growth of the Black *Hamburgh* class, and also of the estimation in which *Brahma* Pootras are held by the Judges. The first prize went to the latter breed shown by Mr. Fowler, second to Mr. Dixon for Black *Hamburgh*, and third to Mr. Leighton for Malays. For *chickens*, Mr. Fowler was again successful, Mrs. Wolferston second with White *Dorking*, and Mr. Dixon third. All these birds deserve separate mention.

The *Game Bantams* were weak, and afforded an easy victory to Mr. T. H. D. Bayley in adults, and to Mr. Turner in *chickens*. Golden and Silver-laced *Bantams* were very weak—so much so that the first prize was withheld. An otherwise excellent pen was disqualified by a faulty comb in one hen. The shape was perfect, but, save the pike behind, it was pointless. The Blacks and Whites were good.

Mrs. Guy showed a pen of excellent *Turkeys*.

In *Geese* Mrs. Seamons was first, and Mr. Fowler second. Mrs. Seamons' White *Geese* weighed 64 lbs., and Mr. Fowler's Grey 62 lbs.

Mr. Fowler took all the prizes for *Aylesbury Ducks*; the pens weighed 19½ lbs., 19½ lbs., and 18½ lbs. Mr. Fowler gained first for *Rouens*. Mr. T. H. D. Bayley took first with beautiful Brown Call Ducks, Mr. Jessop second with *Buenos Ayrean*.

The *Game Cock* entries were better on paper than in the pens. Mr. Clements won easily. Mr. T. H. D. Bayley did the same in *Game Bantams*.

Mr. Holland was indefatigable as Secretary, and we believe the Show was deservedly successful.

GAME (Black-breasted Reds).—First, J. Fletcher, Stoneclough, near Manchester. Second, Capt. Wetherall, Loddington, near Kettering, Northamptonshire. Third, H. Horton, Worcester. Commended, Mrs. Hay, Sudbury, Derby. **Chickens.**—First, A. B. Dyas, Madeley, Salop. Second, H. Bell, Burnley, Lancashire. Commended, Mrs. Hay.

GAME (Brown-breasted Reds).—First, J. Fletcher, Stoneclough, near Manchester. Second, A. B. Dyas, Madeley, Salop. Third, with withheld. **Chickens.**—First, J. Fletcher. Second, H. Parker, Wedington, Salop.

GAME (Duckwings and other Greys and Blues).—First, J. B. Chune, Coalbrookdale. Second, J. Fletcher. Third, G. McCann, Malvern. **Chickens.**—First, J. Fletcher. Second, Messrs. Phillips & Winwood, Worcester.

GAME (Any other variety).—First, J. Fletcher. Second, H. Baker, Bridport, Worcester. Third, W. Daw on, Selly Oak, near Birmingham. Commended, J. B. Weeks, Bromyard. **Chickens.**—First and Second, H. Baker, Bridport, Worcester.

DORKINGS (Colonred).—First and Third, C. H. Wakefield, Malvern Wells. Second, Rev. M. Amphlett, Church Lench Rectory, near Evesham. **Chickens.**—First, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley, Yorkshire. Second and Third, C. H. Wakefield. Commended, Rev. J. G. A. Baker, Old Warden, Biggleswade; Mrs. J. Dain, Lea Brook, Wednesbury; E. Tudman, Ash Grove, Whitechurch, Salop.

SPANISH.—First, J. R. Rodbard, Aldwick Court, Wington, near Bristol. Second, J. Smith, Walsall. Third, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. **Chickens.**—First and Second, J. R. Rodbard. Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury.

COCHIN-CHINA (Cinnamon and Buff).—First, T. Stretch, Ormskirk. Second, H. Bates, Harbourn Heath Cottage, Edgaston. Third, H. Yardley, Market Hall, Birmingham. **Chickens.**—First, W. F. Earle, Edenhurst, Prescott, Lancashire. Second, C. T. Bishop, Lenton, near Nottingham. Third, W. Dawson, Hopton Mirfield, Yorkshire. Commended, Rev. G. Gilbert; H. Bates.

COCHIN-CHINA (Partridge and Grone).—First, Capt. H. Heaton, Lower Broughton, Manchester. Second, E. Tudman, Ash Grove, Whitechurch, Salop. Third, T. Stretch, Ormskirk. **Chickens.**—First, E. Tudman. Second, C. H. Wakefield.

COCHIN-CHINA (Any other variety).—First, G. C. Whitwell, Kendal. Second, W. Dawson, Hopton Mirfield, Yorkshire. Highly Commended, R. Chase, Balsall Heath, Birmingham. Commended, J. Bigger, Northampton. **Chickens.**—First, W. Dawson, Hopton Mirfield, Yorkshire. Second, G. Lamb, Red Hill House, Compton, near Wolverhampton. Highly Commended, Mrs. S. R. Herbert, Powick, near Worcester.

HAMBURGH (Gold-pencilled).—Prize, H. Beldon.

HAMBURGH (Silver-pencilled).—First and Porcelain Vase, T. W. Walsh, Worcester. Second and Third, H. Marshall, Cotgrave, near Nottingham. **Chickens.**—First and Second, T. W. Walsh. Third, H. Marshall.

HAMBURGH (Gold-spangled).—First, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. Second, N. Marlborough, Denton, near Manchester. Third, J. Davies, Harborne, near Birmingham. **Chickens.**—First, J. Roe, Arundel Arms, Wadfield, near Manchester. Second, N. Marlborough. Highly Commended, J. Dixon, North Park, Clayton, Bradford.

HAMBURGH (Silver-spangled).—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. **Chickens.**—First, J. Fielding, Newchurch, near Manchester. Second, Mrs. H. Sharp, Bradford, Yorkshire. Highly Commended, Mrs. H. Sharp; H. Beldon. Commended, J. Dixon.

POLANDS (Gold or Silver).—First, H. Beldon. Second, G. C. Adkins, Lightwoods, near Birmingham. Highly Commended, J. Dixon. Commended, J. Dixon. **Chickens.**—Prize, G. C. Adkins.

POLANDS (Black with White Crests).—First, T. P. Edwards, Lyndhurst, Hants. Second, J. Dixon.

CREVE COEURS.—First, E. Pigeon, Lymington, near Exeter. Second, C. H. Wakefield. **Chickens.**—Prize, C. H. Wakefield.

ANY DISTINCT VARIETY NOT INCLUDED IN THE ABOVE CLASSES.—First, J. K. Fowler, Prebendal Farm, Aylesbury (*Brahma* Pootra). Second, J. Dixon. Third, J. Leighton, Ash Tree House, Cheltenham (Malay). Highly Commended, J. Hinton, Hinton, near Bath; G. Lingard, Snow Hill, Birmingham (Black *Hamburghs*). **Chickens.**—First, J. K. Fowler (*Brahma* Pootra). Second, Mrs. Wolferston, Statfold Hall, Tamworth (White *Dorking*). Third, J. Dixon. Commended, T. P. Edwards, Lyndhurst, Hants, White *Dorking*).

GAME BANTAMS (Black-breasted and other Reds).—First, T. H. D. Bayley, Ickwell House, near Biggleswade, Beds. Second, Capt. Wetherall, Loddington, near Kettering, Northamptonshire. Third, withheld. **Chickens.**—First, J. H. Turner, Fir View, Sheffield. Second, T. H. D. Bayley.

GAME BANTAMS (Any other colour).—Prize, R. Brotherhood, Almondsbury, near Bristol.

BANTAMS (Gold or Silver-laced).—Second, R. Chase, Balsall Heath, Birmingham.

BANTAMS (Black or White).—First, Capt. Wetherall. Second, G. S. Cruwys, Cruwys Morchard Court, Tiverton, Devon.

TURKEYS.—Prize, Mrs. A. Guy, East Grantham.

GESE.—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, J. K. Fowler, Prebendal Farm, Aylesbury. Third, G. McCann, Malvern.

DECKS (Aylesbury).—First and Second, J. K. Fowler. Highly Commended, J. K. Fowler.

DECKS (Rouen).—First, J. K. Fowler. Second, G. Hanks, Quobwell Farm, Malmesbury, Wilts.

DUCKS (Any other variety).—First, T. H. D. Bayley. Second, J. R. Jeece, Beverley Road, Hull.

SWEEPSTAKES.

GAME COCK.—First, G. Clements, Birmingham. Second, J. B. Chune, Coalbrookdale.

GAME BANTAM COCK.—Prize, T. H. D. Bayley, Ickwell House, near Biggleswade.

PIGEONS.—*Pouters* (Any Age or Colour).—First, H. Yardley, Birmingham. Second, F. Else, Baywater, London. Commended, E. M. Pierce, the Castle, Taunton. *Carriers*.—First and Second, H. Yardley. *Almond Tumblers*.—First, F. Else. Second, T. D. Walker, Holyake, Cheshire. *Mottled or other Tumblers*.—Prize, H. Yardley. *Balds or Beards*.—Prize, J. W. Edge. *Owls* (Silver or Blue).—Prize, M. E. Jobbling, Barras Bridge, Newcastle-upon-Tyne. *Owls* (Any other Colour).—Prize, F. R. Else. *Barbs* (Any Colour).—First, F. G. Stevens, Axminster, Devonshire. Second, T. D. Walker, Holyake, Cheshire. *Fantails* (White).—Prize, H. Yardley. *Fantails* (Any other Colour).—Prize, J. W. Edge. *Nuns* (Any Colour).—First, F. Else. Second, J. W. Edge. *Trumpeters*.—Prize, H. Yardley. *Turbits*.—First, F. G. Stevens. Second, H. Yardley. *Jacobins*.—First, H. Yardley. Second, J. W. Edge. *Runts*.—First, E. Pigeon, Lymstone, near Exeter. Second, F. G. Stevens. *Antwerps*.—Prize, H. Yardley. *For any New or Deserving Variety*.—Prize, H. Yardley.

Messrs. Hewitt and Baily were the Judges.

BEE-KEEPING IN DEVON.—No. XIX.

FOUL BROOD.

AFTER racking my brain to the uttermost to divine the cause of the unsatisfactory state of my apiary, as described in my last communication, and taxing my ingenuity in vain to discover a remedy, it at length occurred to me that all this mischief might possibly arise from that fatal scourge of continental and American apiaries denominated "foul brood." On referring to bee-books in which this disease is mentioned, I became convinced that my conjecture was correct, and that I had a no less formidable enemy to contend with. This, then, accounted for all my difficulties; and as a disease when known is said to be half cured, I was at any rate relieved from uncertainty, and had the knowledge and experience of others to guide me to a remedy. It may probably appear to many not a little singular that this explanation did not occur to me before, and on looking back it does seem rather surprising that I should not have made the discovery earlier. But it must be borne in mind that I had never before to my knowledge met with a case in any respect similar, and that although I had perused both German and American descriptions of the malady, they had appeared to me to relate to a state of things which was unknown in this country, and had almost entirely faded from my recollection, as referring to matters with which I was never likely to have any concern.

There could, however, be no doubt as to the actual fact. My colonies without a single exception were the victims of this fatal pestilence, and all must speedily perish unless prompt and efficacious remedies were resorted to.

After reading all I could meet with on the subject, in German, American, and English bee-books (for I discovered that the disease was mentioned by Dr. Bevan and other English authors, although under different names), I at length began to comprehend the matter, and understood also at the same time by what means all my stocks had become inoculated by the fatal virus. Knowing how great an assistance it is to bees to be furnished with combs, I have long been in the habit of purchasing in my own neighbourhood, and through friends in various localities at a distance, empty combs from swarms that had perished of starvation; and from the experience which I have recently bought at so great a cost, I now know that some of these had belonged to bees which had really died from foul brood, and by using these combs in various hives I had spread the infection throughout my apiary.

Having, therefore, identified the disease, and traced it to its source, the next step was to apply a remedy; and here, for the better understanding of my after-proceedings, I may state that all authorities agree in stating that this malady does not in the least affect adult bees, but is confined to the brood. The hive in which a diseased colony has been domiciled, as also their combs and the honey they contain, are, however, capable of inoculating a healthy stock, and for this reason bees from other colonies robbing a foul-breeding one may convey the infection to their own hives. On this account all my operations were conducted towards evening, when, contrary to the usual practice of the criminal popu-

lation of mankind, the marauding spirit among bees is by no means so active as during the forenoon, and in the full glare of a midday sun.

My first experiment was with a couple of pure Italian stocks which I had contrived to keep tolerably strong; and which I therefore deemed equal to furnishing each a moderate artificial swarm, whilst leaving sufficient bees in the parent stock to hatch-out what healthy brood might remain, and possibly also to raise queens therefrom. Providing, therefore, a clean hive furnished with what, at the time, I considered to be pure comb, I first ensconced the queen therein (having temporarily confined her in a small cage to prevent her being lost during the confusion), and taking out the combs one by one, brushed every bee from them into the new domicile. All this was done as expeditiously as possible in order to give the bees little time for filling themselves with polluted honey from their old hive, and in a few minutes they found themselves with their queen in a strange habitation removed to another part of the garden, whilst the deserted hive occupied its old position. There it received such bees as were absent during the operation, as well as a constant accession of numbers during the next few days from bees returning to the old spot, and the hatching-out of such young ones as had escaped the fatal infection; but although many royal cells were formed it failed to raise a queen. The result was also a failure in the case of the swarm in which the disease reappeared as soon as the brood was sufficiently advanced to admit of its development, and which, therefore, necessitated the repetition of the operation in the different and, I believe, more effectual form which will be hereafter described. This unfortunate result may, I think, be attributed to infection lurking in some of the combs with which the swarm was furnished, and which I fancy must have been at some time during this summer in one of my diseased hives, although I was not cognisant of the fact at the time I used them.

My proceedings with the second colony were also precisely similar to the foregoing; but, unlike the first, appear thus far to have been completely successful in conquering the malady, of which no farther symptoms have manifested themselves, but in this case, also, the bees remaining in the old hive failed to raise a queen.

The next move was of a somewhat different character, and involved a trip of a few miles into the country, which I made in the beginning of this month (July), and there I purchased a couple of swarms—a first and second—both good of their kind, one hive being filled with comb tolerably heavy and very populous, whilst the other was two-thirds full and contained a good number of bees. The latter I tied up in a cloth and brought home at once; but, to my great mortification, nearly all the combs fell during the journey, and many were so damaged as to be useless. The remaining combs and bees were transferred to a clean box and supplied with empty combs. Unfortunately, like those before mentioned, they could not have been pure, for the disease subsequently showed itself in two combs; but these having been at once removed it has not again appeared, and the stock now seems perfectly healthy. I may add that since its sojourn in my apiary its black queen has been deposed, and has made an involuntary migration to St. Austell, in the neighbouring county of Cornwall, where I shall be very glad to hear of her well-doing, and that a very beautiful yellow queen from one of my own hives reigns in her stead.

Two days afterwards I took a second excursion, bargained for another prime swarm, and drove the one I first purchased into a box furnished with empty comb. Placing them in their accustomed position, and leaving them to make the best of their poverty-stricken condition, I brought home their original well-furnished habitation, and having consigned it to a warm corner in the kitchen during the night, proceeded the next morning to cut out every comb and fit and fix them into frames. This done, one filled with brood was applied to the assistance of one of the artificial swarms whose formation I have above described, whilst the others were placed in a clean hive, into which was rapidly swept the population of a Ligurian stock whose infected combs were drained of honey and consigned at once to the melting-pot.

The next day I repeated this proceeding with the other prime swarm, installing the bees in a box furnished only with

a few pieces of empty comb, and substituting its beautiful pure combs and healthy brood in a clean hive for the polluted combs of a Ligurian stock.

It is worthy of remark that all the combs of these swarms, although, of course, quite new and clean, were of a bright gold colour. This is invariably the case with combs fabricated in the district a few miles west of me, and must, I imagine, be attributed to some peculiarity in the pasture, since my own bees always make perfectly white combs. Being thoroughly familiar with this fact, I was much amused some time ago by a gentleman in this county, whose bees had evidently perished of starvation, fancying they had been poisoned because their combs were yellow, and forwarding a piece to one of your contemporaries with the view of having it analysed!

I am happy to state that these two last operations appear perfectly successful. The Ligurian queens are now going ahead in their wonted fashion, laying both worker and drone eggs in profusion, whilst the cheerful hum of their indefatigable subjects, again restored to hope and activity, discourses sweet music to the ears of—A DEVONSHIRE BEE-KEEPER.

FAILURES IN BEE-KEEPING.

As a bee-keeper of several years' experience, I have not been inattentive to modern proceedings in regard to these interesting creatures, and especially the so-called scientific methods of management from time to time recorded in your pages. In particular I looked forward with some expectation for such an instructor as "A DEVONSHIRE BEE-KEEPER," at the same time harbouring a shrewd suspicion that Nature was equal to her own work, and that bees wanted no artificial help in swarming, in comb-building, or in any other part of their proceedings. The communication of "A DEVONSHIRE BEE-KEEPER," at page 59, leaves me no cause for regret that I have maintained my faith in the simple, cheap, old-fashioned straw hives, undisturbed with perpetual meddling by amateur honey-makers and queen-improvers. The woeful account your correspondent gives us of the present state of his scientific apiary induces me to turn with satisfaction to my inexpensive row of straw hives, giving me neither trouble in management nor anxiety about the harvest in due season. My little favourites seem to say to their proprietor, "Let us alone, and we can transact our own affairs, weather permitting, and that you cannot alter by any of your new-fangled devices." I turn with confidence to the words of one of our best instructors, Mr. Golding:—"Let my readers repel," says he, "the quackery which would have them believe that it was the kind of hive which commanded the honeyed store: that will depend on the season and the locality." And to the like effect writes Mr. Taylor, in his "Bee-keeper's Manual":—"The most that can be done with permanent advantage is to furnish our intelligent little workmen with a dwelling convenient in its form and management for the intended purposes, bearing in mind, as a general rule, that these are best consulted by attention to simplicity in its details."—AN OLD-FASHIONED BEE-MASTER, *Finchley*.

CLOUDED-BRINDLED MOTH—PIPING—COLOUR OF LIGURIAN QUEENS.

I PICKED the enclosed moth up at the mouth of my observatory-hive, in the evening of the 20th July, and fancy it had been killed in trying to get into the hive. Will you say if it is the wax moth?

The same day I had a second swarm from my observatory-hive. This is a second maiden swarm from a first swarm on the 14th of June, and a hybrid queen, which makes six queens from this first swarm, besides filling the hive and a glass with honeycomb and grub; but on my return home in the evening, and looking into the hive, I found all the bees had gone back, and the largest queen, I enclose, on the alighting-board nearly dead, and this morning the small one was thrown out. Will you say if she is likely to swarm again after this? as last evening I heard piping going on, and, therefore, suppose the queen thrown out last evening must have been this queen. Will you say if these queens

are as light-coloured as the true Ligurian queen? as some I had from a Hermann's queen that throws beautiful bees, were dark queens.

In reference to the remarks of the "DEVONSHIRE BEE-KEEPER," in your No. 120, July 14th, regarding the colour of bees, I have a last-year's Ligurian queen, in whose progeny there is hardly a yellow-handed bee, and I therefore conclude that she must have had intercourse with a common drone. I have also some hybrid queens that throw many yellow-handed ones, and some queens that you can hardly see a yellow-handed bee in the whole hive.—B. B.

[The specimen which accompanied your letter is called the clouded-brindled moth (*Xylophasia hepatica*), and is not a wax moth. The scent of the honey was probably what attracted it to the hive's mouth. Piping is a sign that the stock is likely to swarm again. The queens sent appear as light as many true Ligurians; but these latter vary so much in colour that no dependence can be placed upon it. The only test we know is the colour of their worker offspring.]

STUPIFYING BY CHLOROFORM—BEE-SEASON IN IRELAND.

Will you point out the best manner of using chloroform, so as to stupify bees without killing them, while taking their honey? This being an unusually good year for bees, the information would be valuable to many.

In your Number of the 14th inst. I see that in England it has been a bad season for bees. In Ireland, on the contrary, it has been a singularly good one. For many years I have had no honey; and this week I have already taken a hive containing from 3 to 4 stone of virgin honey, and I have several other hives nearly fit to take.—A CONSTANT SUBSCRIBER.

[The following directions for using chloroform we extract from pages 27 and 28 of the new and enlarged edition of Payne's "Bee-keeping," just published at our office:—

"The necessary dose is a quarter of an ounce, or two teaspoonfuls, poured into a piece of rag doubled twice, and placed on the floor-board of the hive, which must be lifted up for the purpose, the entrance-hole being carefully secured. In about two minutes and a half there will be a loud humming, which lasts about one minute, when all is quiet. Let the hive remain in this state for six or seven minutes longer, making altogether about ten minutes. Remove the hive, and you will find the greater part of the bees lying senseless on the board. There will still be a few clinging between the combs, some of which may be brushed out with a feather. They return to animation in from half an hour to one hour after the operation. The expense is 3d. per hive.

"This plan, unlike the usual mode of brimstoning, and the more modern plan of fumigation by fungus or puff-ball, is easily carried into operation, and the flavour of the honey is not injured by the fumes; but it is said to be highly injurious to the bees."]

WEDDING FLIGHTS OF A YOUNG QUEEN.

ALTHOUGH I have seen it surmised that queens have intercourse with more than one drone, yet I never heard of any one actually having observed that such was actually the case.

On the 10th of July on returning home at about 5 P.M., the queen in my unicorn-hive exhibited evident symptoms of impregnation, and at about seven I actually saw her rid herself of the incumbrance. On the 11th she again exhibited signs of fecundation, and on the 14th began to lay. From this I should infer that a queen may lay both perfectly pure Italian brood, and also that which will produce half-bred bees; and this may, in a measure, account for the extraordinary difference which exists between individuals in the progeny of some queens. This queen is remarkably well coloured, I think better than any one I have seen yet. The senior princess was so dark that I could not perceive the slightest trace of her Italian origin. My Italian queens have proved amazingly prolific, far beyond anything I have witnessed in our own indigenous species. One of my drones

last year evidently impregnated one of the queens in Lord Dartmouth's apiary at Patshull, as she breeds a good many clearly-marked Italian bees. Patshull is about two miles in a direct line from my house.—J. E. B.

[This observation confirms the correctness of Huber, whose relation of a similar occurrence will be found in page 309 of the edition of 1841. We have long suspected the fact but have never succeeded in witnessing it. We should be glad to know if this queen turns out unusually prolific, even for a Ligurian, as M. Hermann declares such to be the case.]

ITALIAN BEES.

HAVING had more than three years' experience with these bees, I send you some important facts respecting them which have fallen under my observation, and which I believe have not yet been given to the public.

1. The queens are not only more prolific, as previous writers have remarked, than those of the common kind, but are much more disposed to keep their brood compactly in the combs. An Italian colony will often have in two or three combs as large a surface of brood as the black queens will ordinarily have in four or five. The habit of squaring out their work is more particularly noticeable in the early part of the season, and its importance will be readily appreciated by every skillful bee-keeper.

2. The Italian bees, when forage is abundant, are far less disposed to rob than the black bees.

As this fact is not only highly important, but directly contrary to the common opinion, the evidence of it will be given somewhat in detail.

Having purchased, last summer, a number of stocks of black bees in moveable comb-hives, I examined them when the fruit trees were in blossom, in order to learn the condition of each colony. After a few hours spent in this work, the bees would follow in great numbers whenever they saw me approach a hive to open it. I was very much surprised to notice that nearly all the robbers were black bees. I cannot be mistaken as to this fact, as both myself and my son spent some hours, for several days, in examining those hives. Some drone-combs having honey in them were exposed to the bees, so that when emptied they might be used for breeding Italian drones; and these combs were soon covered with black bees, very few Italians alighting upon them, although I had a large number of strong Italian colonies. This year, having only a few black bees, and more than eighty Italian colonies on my premises, nearly all the bees that attempt to rob hives when they are opened, or to light upon combs containing honey, are of the black kind.

I have pointed out these facts to many who have visited my apiary, and the general opinion is, that when forage is abundant, Italian bees are so eager to gather honey from the blossoms, that they have very little inclination to secure it from other sources. It would be difficult to over-estimate the importance of this peculiarity in an apiary where moveable comb-hives are used, and where artificial swarming, and other manipulations which require the hives to be opened, are practised.

It is true that when forage is scarce the Italian bees are as much disposed to rob as the black, if not more so; but the assertion that they cannot be kept near the stocks of black bees without robbing them of their stores is erroneous. Mr. Quimby, who has had excellent opportunities for testing this point, has said enough to convince any unprejudiced bee-keeper that they may be safely kept in close proximity to common bees, and my own experience perfectly agrees with his.

3. The Italian bees will work upon the second crop of red clover.

Three years ago I had twelve swarms of black bees early in June, to three of which I gave, when hiving them, Italian queens. The hives were tolerably well filled with combs by the black bees, but before the young Italians began to gather stores, the honey-harvest was nearly over. In August the state of my health prevented me from making any observations; but a member of my family noticed that while the three colonies with the Italian queens were working

vigorously, the other nine were doing very little. In September I found that the Italians had their winter's supply, while the best of the others had only a few pounds of honey, the season proving one of the worst that I ever knew. The black colonies were broken up, and the bees added to other stocks, while the Italians wintered in good condition. I am now satisfied that the Italians obtained their August stores from the second crop of red clover. Last August I noticed the Italians working vigorously on the red clover, and saw very few black bees upon it. Mr. C. W. Taylor, of Hulmeville, Bucks Co., Pa., who had been so successful in rearing these bees, wrote me last summer that his bees were filling boxes and frames with honey gathered from red clover, while the black bees in his vicinity were doing nothing. Other persons have written to me to the same effect.

In regions where buckwheat is not much cultivated, and where full forage is scarce, this peculiarity of the Italian bees will in some seasons make the difference between a handsome profit and a severe loss in bee-keeping.

While it is true that some foreign writers have asserted that these bees will work upon the red clover, I have not met with any statement that they scarcely notice the first crop, but confine their operations almost wholly to the second crop, or seed clover, which blossoms when the white clover has passed out of bloom, or yields little if any honey.

I will state, as a matter of interest to bee-keepers, that the three Italian colonies before mentioned produced me the second season 350 lbs. of honey, and one large swarm.—(L. L. LANGSTROTH, in *American Country Gentleman*.)

OUR LETTER BOX.

CHICKENS DYING SUDDENLY (*A Subscriber*).—It is always difficult to arrive at the cause of sudden death in chickens, but it is more particularly so when they are only three weeks old. The most natural conclusion, when death follows seizure within a few minutes, is that they pick up something poisonous, which acts immediately. Polish chickens are supposed to be subject to attacks while the top knot is growing. We know of no remedy so rapid in its effects provided the chickens when seized are in health. We can only tell you the *regime* we should adopt to keep them in health. They should be on a dry spot, and the hen should be under a fig; they should have dust at hand to dust and bask in; they should be fed on ground oats as their principal food, and be well supplied with stale bread soaked in strong ale. We do not think you would lose them if you follow this treatment.

MORTALITY AMONG YOUNG POULTRY (*E. B.*).—Both the Turkeys and the chickens are suffering from roup. It is probable your Turkey hens have been allowed their liberty, and have dragged their poult about, as is their wont, till they have been half perished from damp and dew. Let the hen Turkey be confined—in an empty china crate is a capital thing for the purpose. Give the poults stimulating food, barley and oatmeal mixed with peppercorns and onion tops; let them have plenty of bread and ale. Let the rip in which the hen is confined be moved every day that there be no collection of dirt. Give the Turkeys Baily's pills. As the pullets are only just attacked they will recover if they are removed from the infected spot, and fed well on bread and ale. In both cases camphor in the water is an excellent thing.

CORNS IN A COCK'S FOOT (*W. C. H. H. D. A.*).—Sometimes the apparent corn on the foot of a Dorking cock is the result of an injury, or a thorn, or a small gravel stone driven through the skin when the bird flies from the perch. If such be the case the cure is easy, as the cause is plain; but if it is the result of age and the weight of the body it has to carry, it is, we fear, incurable. The progress of the malady may be arrested by keeping the bird as much as possible on the grass, and by having very low perches. If the swelling arises from any foreign body in the foot an opening will, of course, relieve it; but if it does not, it will only make bad worse.

RED CAPS (*W. W.*).—The Red Caps are a breed of fowls peculiar to Lancashire. They are akin to the Golden-spangled Hamburgs, but not subject to the same rules. We do not know them sufficiently to be justified in giving their points, nor can we speak of their laying properties, as we have never kept them.

TRANSFERRING BEES (*C. Major*).—Full instructions for transferring stocks into frame-hives were given in No. 75 of our third volume. The operation may be performed at once. We do not know any professional apiarian from whom you could obtain the required assistance.

LONDON MARKETS.—JULY 27.

POULTRY.

The season tells its tale. The supply increases, and the demand falls off. Prices suffer in consequence.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 74.4°, and its night temperature 51.1°. The greatest heat was 93°, on the 10th, 1842; and the lowest cold, 36°, on the 6th, 1833. The greatest fall of rain was 1.06 inch.

AUTUMN PROPAGATION OF BEDDING PLANTS.

THIS is a topic which has so often been elaborately treated of in the pages of this Journal, and one about which it may be considered most difficult to say anything to better purpose than has already been advanced by men of long and large experience. He would be indeed a bold and presumptuous individual who would suppose that by anything like superior force or authority he could set aside all or anything that has been so well and fully said. There cannot be any who believe less than I in a gardening Hercules who would presume to step into the tide of gardening affairs, and attempt to guide all others into the course which he may think best. It may, however, be safely admitted that the authoritative saying that "in the multitude of counsellors there is wisdom," is peculiarly applicable to every department of gardening.

Depend upon it, men of spheres the most circumscribed may be as well able to teach and suggest on some particular topic, as are those who have the direction of operations on the most gigantic scale; and we have each so much to learn in all that is comprehended in that wide and ever-widening word—Gardening, that it ill becomes any to hold forth with tones of imperious dogmatism on whatever subject he may think proper to treat. The diversity of ways and means with which different individuals accomplish results in many respects alike are almost as different, in some parts of their details at least, as are the individuals themselves; hence the never-failing interest that is kept up on the subject of gardening, and the certainty that may be assumed that, however different the doctrines that may be advanced and the method described, they cannot fail to prove of service to a few, at least, of the many who peruse these pages, even if from circumstances over which they may have no control they may not be able to follow out the ideas and practice which are from time to time brought forward.

I therefore cast in my mite into the mighty treasury which has already been formed in the pages of this Journal on the subject of bedding plants, and hope that as the season of propagation is close at hand, some tyro may benefit by what shall be briefly advanced.

If we could but fully understand the means by which the most important results are accomplished in the great laboratory of Nature, it would invariably be found that the means are in themselves simple, although, like all else in the abstract, marvellous. And so I think it is found to be in gardening: the simpler the means, in

most cases the greater and more satisfactory the results. For a good many years I have made it a point for attainment to produce a given quantity of flower-garden plants by the simplest possible means consistent with the production of a first-rate article. I do not mean by this the many resorts and makeshifts which might be called into operation, and which, after a good deal of experience in that sort of thing, I have come to regard as most unsatisfactory and the most expensive by far in the end. Here as in everything else, depend upon it, what is worth doing at all is worth doing well; and in flower-gardening as attempted in numerous instances at the present time, it would be a wise and satisfactory procedure if the area of flower gardens were much reduced and the remainder better executed. This would be a great step towards rendering flower-gardening what it might be—one of the most delightful departments of a gardener's duties, instead of that which heaps upon him an untold amount of drudgery. It would, moreover, cover the present style of flower-gardening from the many objections which some raise against it. That the season of full beauty could be nearly doubled in duration by means of differently managing the plants now in use is a fact which has been fully proved; and this, too, without more labour—by simply reducing the area to be planted, and which is perfectly consistent with an enhanced degree of pleasure and enjoyment; for it is a fact beyond all dispute that a few beds may be made far more exquisite and effective than ten times their number as we sometimes meet with them.

And this is only one of the many advantages that would be gained by a different mode of procedure. It would relieve hothouses which have been erected expressly for other purposes from being turned into Pandora's boxes. After having had a long spell at turning out thousands of plants from forcing-houses and hardening them off by almost every means that could be devised; and on the other hand, after the experience of a better-ordered state of affairs, the fact has forced itself upon me most convincingly, that the makeshift system is by far the most expensive, fifty per cent. more laborious, and equally more unsatisfactory in results, than when erections are afforded for the purpose. In this, as in everything else, there is a vast amount of unfruitful mental and bodily wear and tear, mishaps, and disappointments, and to a great extent abortive results, when that which is aimed at is altogether out of proportion to the means at command. And in flower-gardening, as now practised, gardeners themselves have plunged headlong without adequate means into an amount of labour, from which in many cases they would be glad to retreat; and after all, the splendour of the parterre is only of two or three months' duration, while it might be extended to nearly double that period, if the means and extent were more in character and proportion. If ever flower-gardening is to be raised many steps above its present level some course of this sort must be insisted on, as well as some alteration of the general principles now observed both in the character and arrangement of the plants.

In the autumn propagation of all flower-garden plants, excepting *Geraniums* and *Calceolarias*, the object is simply to prepare enough of stock from which to propagate in early spring sufficient numbers to meet the requirements of the place. Spring-struck plants, as is well known, are much to be preferred to those struck in autumn and winter; and the labour connected with such numbers is confined in the one case to weeks, while in the other it is spread over months.

Looking at cuttings, let us say of *Verbenas*, *Heliotropes*, *Alyssum*, &c., before they are taken from the parent plants, there we find them in all the health and vigour attainable in a rich soil and under the influence of full sun and air. The end to be attained is not simply how to get these rooted and established as independent plants: this could be effected in many ways. But the question is how to effect it in the easiest, soonest, and most convenient way, and with the least possible amount of debility entailed on the plants in the process; and after they are thus rooted, how best to treat and dispose of them so that they can be wintered in the greatest health and robustness possible.

After having tried a good many methods of preparing a stock that is at the same time healthy and numerous enough to enable short work to be made of the spring propagation, I have found something like the following order of things to be the most satisfactory of any course that I have yet tried, although others may arrive at precisely the same end by different routes.

Early in August about a foot of last autumn's tree leaves are put into the bottom of a cold frame, and beat firmly down. Over the leaves is put about 3 inches of soil, consisting of equal parts of loam, leaf mould, and sand well mixed together. This is beaten firmly down with the back of a spade, or any similar appliance, and in this state the frame is in readiness for the cuttings; the required number of the different kinds is selected from the margin of the beds, or from wherever they can be most readily had. There is not much ceremony about the selection and preparation of *Verbena* cuttings, only that they are short, stubby, fresh cuttings that have not yielded blooms, and that the leaves are removed from the bottom joint to prevent damping. They are made, dibbed into the frame, and watered with as little delay as possible, so that they are not allowed to droop and get injured by being dried up. When the necessary number is in they receive water through a very fine rose sufficient to moisten the 3 inches of soil. The frame is closely shut down, and rather thickly shaded during sunshine. In fact, everything is done to keep them as cool as possible. If the evenings are calm the lights may be entirely drawn off for a few hours, and when put on for the night air is left on. In the morning, if the day is likely to be hot, they are dewed over through a very fine rose or syringe. Under such treatment they root with little trouble and without making much growth at the top—at least, as compared with similar cuttings struck later in the season in warmer quarters. The object is to get roots formed with as little heat and stagnant atmosphere about the cuttings as possible, and so prevent their being drawn and weakly.

When they have made roots about an inch long they are pricked-off into round earthenware pans, 14 inches in diameter and 7 inches deep. The pans are prepared by placing a thin layer of rather finely-broken crocks over the bottom, then a layer of old mushroom-bed dung, which consists chiefly of horse-droppings, and they are filled up with a good substantial compost consisting of equal parts of a rather sandy loam and the same sort of dung already named, with a very slight addition of sand. About thirty plants of such as *Verbenas* and *Alyssum* are put into each pan, and as soon as possible after being pricked-off they are fully exposed to all weathers except heavy rains. By housing time you might shear armfuls of fine healthy cuttings from them. They are, of course, repeatedly stopped, and kept free from bloom-buds as they grow, and carefully attended to with water. We make up about eighty or a hundred pans of *Verbenas* in this way; and they are wintered in any cool, airy, dry place, and kept moderately moist at the root; and even with such varieties as *Purple King*, which is largely grown, milkew rarely makes its appearance.

In spring almost any amount of cuttings can be had from such a stock. Last spring we struck about twenty thousand

Verbenas alone in a very short time, and three times the quantity could have been struck if needed. As compared with plans that I have formerly adopted, and which used to be in vogue, this is found to be attended with far less labour and much better results.

In the case of *Geraniums* the middle of August is considered a good time to make a commencement (except in the case of *Golden Chain*, which is always surest if in a fortnight earlier); and if all can be put in by the middle of September it is a great deal better than later attempts. After trying a good many ways in striking all the different varieties of variegated *Geraniums* I prefer striking them and wintering them in eight-inch pots. They are not very heavily but carefully crocked. Over the crocks is placed a layer of mushroom-dung; and the pot is filled to within 3 inches of the brim with one part loam and one part leaf mould, and is then filled up with the same soil after mixing another part of coarse pit sand with it. The number of cuttings put into each pot varies from eighteen to twenty-four according to the size of the sorts. Large cuttings are preferred as those which root soonest, are least likely to damp-off, and make the finest plants in spring. These are dibbed into the pots immediately they are made, watered, and placed in a position where the pots will stand on a dry bottom, and be fully exposed to the sun all day long, with no covering at any time, unless it be to throw off heavy and continued rains. Most of the larger leaves are removed in making the cuttings, but in no case are they dried before being put into the cutting-pots, never being able to discover what was gained by such drying except mischief. In hot days, when water may not be needed in the soil, the cuttings are slightly dewed over in the evening when the sun has left them.

I have found that cuttings struck and wintered in pots of the size recommended keep much better, and are more conveniently managed, than when put into either smaller or larger sizes or into boxes. The advantage over boxes I conceive to be derived from the better drainage secured, and the more free play of air and light among the plants when in smaller and round detachments. The earthenware has also a little to do in the matter. The whole winter they are kept very dry, and in spring when shaken out of the soil there is a great amount of irritability about the whole plant, and their bunches of white roots are almost ready to take up the very sand itself.

The common scarlet varieties are struck and managed in the same way, except that the great bulk of them have been put into boxes to economise space. But from the conviction that they do so much better in pots fewer of them will be put into boxes in future, but will be managed the same as detailed in the case of the variegated sorts. There are usually struck more than 15,000 plants, and a little calculation will show that at the rate of eighteen to twenty in an eight-inch pot it will not require such a vast space to winter them in.

I will not at present enter into the many methods which might be adopted under various circumstances, but have simply given what—after having tried various ways—I have found to be the most sure and satisfactory mode where such means as are necessary are at command. D. THOMSON.

ALEXANDRA PARK FLOWER SHOW.

FLORISTS' FLOWERS.

In commenting generally on the features of this most excellent Show I adverted amongst other things to the *Roses*, and to Mr. Keynes' especially. Nowhere this season have I seen such flowers, nor indeed do I ever recollect seeing such a box as his of 100 blooms was. I thought on looking at them that they must have been grown on the *Manetti* and were maiden blooms, a condition in which I know marvellous blooms are sometimes produced; but on saying so to him I was assured it was not so—that they were all from standards, the more credit then is due to him. The water-pot must, I think, have been well used during this dry season to have produced such flowers. Where all were good it seems needless to particularise; but I may say that the following were superb:—*Duc de Rohan*, and *Maurice Bernardin*. These flowers are, I am per-

suaded, not so extensively known as they ought to be. When I saw them at Messrs. Frasers' last year I noted them as amongst the best of the then new ones, and the magnificence of these two blooms fully justified my preference. Then there were Gloire de Vitry; Madame Boutin; Jean Bart; Paire de Terre Noire, with more stuff in it than ever I have seen; Louise de Savoie (Tea), very beautiful; Louis XIV.; Charles Lefebvre, grand; Céline Forestier; Duchesse d'Orleans; Gloire de Santenay, equal to Senateur Vaisse; Madame Clemence Joigneux, I do not regard this flower as like John Hopper—it is more open, not so compact; Madame Julie Daran; La Brillante; Alphonse Damazin, very fine; Mathurin Regnier; Pourpre d'Orleans; Général Castellane; Gloire de Bordeaux (Tea), this Rose has this year come very dark and disappointed growers—I fear it was too much of a Gascon, but sometimes I have seen it very beautiful; Prince Léon; Duc de Cazes; Robert Fortune, very curious; Souvenir de Comte Cavour, most beautiful; Catherine Guillot; Olivier Delhomme, beautiful; L'Ehloissante; Virginal, a lovely bloom, equalling Mademoiselle Bonnaire in her best days; Triomphe de l'Exposition; Monsieur Joigneux; Vicomte Vigier; Devoniensis; Senateur Vaisse, a splendid bloom; Lord Raglan; Evêque de Nîmes, as only Mr. Keynes can grow it; François Première; Mademoiselle Eugénie Verdier; Madame Furtado, fine, pity 'tis she is so delicate; Madame Charles Wood, very fine; François Lacharme; Reynolds Hole; Professor Koch, beautiful shape; and Madame Charles Crapelet. In Messrs. Paul & Sons' were Lord Clyde, very fine; Madame Charles Wood; Lord Raglan, a beautiful scarlet; Madame Boutin; Evêque de Nîmes; Triomphe de Caen; Cardinal Patrizzi; Gloire de Santenay; Christian Puttner, very good; La Boule d'Or, very fine; La Reine; Madame William Paul; Madame Charles Crapelet; and Senateur Vaisse. Mr. W. Paul had in his collection, which obtained the third prize, Beauty of Waltham; Eugène Appert; Louise Magnan; Souvenir d'Elise (Tea), very fine; Bougère (Tea); Senateur Vaisse; and Emile Dulac.

In the Class for 50, three trusses of each, Mr. Keynes was again first. The most noticeable of his blooms were Olivier Delhomme, Vicomte Vigier, Paire de Terre Noire, Céline Forestier, Virginal, Triomphe de Rennes, Clement Marot, L'Ehloissante, Senateur Vaisse, Gloire de Bordeaux, Charles Lefebvre, Mademoiselle Eugénie Verdier, Beauty of Waltham, Madame Charles Wood, and Gloire de Santenay. In Messrs. Paul & Sons' collection, which obtained second prize, there were fine blooms of Beauty of Waltham, Eugène Appert, Lord Clyde (which promises to be a most useful flower), Prince Léon, Baronne de Noirmont, Pauline Lanzezeur, Louis XIV., Souvenir de Leveson Gower, Comtesse Cécile de Chabillant, and Madame Furtado. Mr. Francis was third, and had fine blooms of Duc de Cazes, Anna de Diesbach, Général Jacqueminot, Madame Vidot, Souvenir de Leveson Gower, Lord Raglan, Duchesse d'Orleans, Triomphe de Rennes, and Prince Camille de Rohan, which promises to be one of the best dark Roses we have.

As I have already intimated, Amateurs did not come out in very full force; Mr. Corp, of Milford, being first in both classes, and Mr. J. C. Perry, of Birmingham, second. Amongst the flowers of the former gentleman I noticed Senateur Vaisse, Général Jacqueminot, Acidalie, and Souvenir de Comte Cavour; and amongst Mr. Perry's, Comtesse de Chabillant, Senateur Vaisse, Général Jacqueminot, and Gloire de Dijon; but in truth, after looking at the splendid flowers in the Nurserymen's Class, one's eye became dissatisfied with, no demerit to them, the inferior blooms of the Amateurs.

Mr. Charles Turner exhibited some fine Pelargoniums, taking into account especially the time at which they were exhibited. They were compact plants and of newer kinds than we see ordinarily at the earlier shows, comprising Murillo, Regina Formosa, Rosine Margottin, Lord Clyde, Tycoon, Lord Palmerston, and Conflagration. He had, also, two splendid stands of Carnations and Picotees, which justly excited the admiration of all the visitors, who might well wonder that no better encouragement has been given to such lovely flowers. Amongst Picotees I noticed especially a seedling purple, Flower of the Day, Maid of Clifton, Col. Clark, Northern Star, and Garibaldi; while amongst Carnations, Samuel Moreton, Duke of Wellington, Seedling 1282, Flora's Garland, Florence Nightingale, Fanny Gardener,

Squire Meynell, Confederate, Splendour, and W. Chapman were conspicuously fine, although I may say that it was a matter of extreme difficulty to select where all were excellent.

In Hollyhocks, Messrs. Downie, Laird, & Laing, of Stanstead Park, sent some magnificent blooms. Amongst them were fine blooms of George Keith, Stanstead Rival, Excelsior, In Memoriam, Lady Dacres, Purple Prince, Walden Masterpiece, Mrs. F. Mackenzie, and Sambo.

Messrs. Paul & Son had another collection, the best of which were Morning Star, Illuminator, and General Havelock.

There were also some fine stands of Verbenas, Mr. Perry, of Birmingham, taking first prize with a fine collection, amongst which were Nemesis, Géant des Batailles, Magnificus, Foxhunter, and some promising seedlings.

Dahlias, too, were exhibited by Mr. Charles Turner; and some stands of Pansies, although the season of the year was too far advanced for them, by Downie & Co. and other growers; but no one, I think, could fail to see how much of attraction had been added to the Exhibition by the many fine stands of florists' flowers, and the miscellaneous objects sent in. I have already alluded to Mr. Cutbush's table decorations. Messrs. A. Henderson's hanging-baskets were also excellent. Mr. Williams, of Holloway, too, had some very pretty stands, arranged with Caladiums and other plants beneath them growing in cocoa-nut fibre, and I have been surprised to see how well they thrive, and for how long a time too in such situations. Altogether there was enough to satisfy all comers; and if the future of the Alexandra Park Company is to be measured by its opening, it has a long career of success before it. It is but fair to add, that notwithstanding the unlooked-for pressure laid upon him, Mr. Mackenzie was enabled to evolve order out of the chaos, so that when the Show opened no one would have believed what it had been so short a time previously, and he, moreover, managed to do it all with extreme kindness and courtesy to all concerned.—D., Deal.

BOILERS.

(Concluded from page 62.)

By the points advocated in my last communication I will test a few of the boilers now in use.

SADDLE BOILER.—It exposes a large surface to the direct, but an inconsiderable amount to the indirect, action of the fire; holds a large body of water; is not liable to get out of order, nor to be soon worn out; being wider at top than bottom, the circulation is sluggish; and even the flues require frequent cleaning out, or it heats more slowly than usual. It cannot be repaired, but it seldom needs repair; it heats slowly; is the easiest managed of all boilers; burns coal well, and when the draught is good, coke also; requires frequent attention; is difficult to regulate, and for the most part incapable of being cleaned out, but that, of course, could soon be rectified. A saddle boiler costing £20 exposes about 25 feet of surface to the direct action of the fire, and about the same quantity indirectly. Now this surface measured by an engineer's standard—a foot of exposed surface will heat to 212° 25 gallons of water—shows the heating powers to be $50 \times 25 = 1250$ gallons, or, with the water in boiler, 500 feet of four-inch pipe; but the boiler in practice will heat more than the calculated amount of piping. I would not adopt such a mode of calculating, for much depends on the heat of the fire and the material giving the heat. Coke when burning is nearly as hot again as slack coal undergoing the same changes. I consider 20 feet of surface directly exposed will heat more water than 100 feet of surface indirectly exposed to the action of the fire, or, in other words, 1 foot of direct surface to heat 50 gallons of water, and 1 foot of indirect to heat 10 gallons only, and if we adopt that mode of calculation a ready estimate is afforded of the heating powers of a boiler.

In my opinion the fire ought to heat the lowest part of a boiler first; but if the fire strikes or heats the lowest parts, and the return-pipe comes perpendicularly (except a short bend), into the boiler, the heated water may rise up it instead of passing through the boiler to the flow-pipe, and should that take place the water cannot flow freely. In a saddle boiler this is prevented, for the greatest heat is at the upper part of the saddle, so that if the water becomes

heated at all it must pass into the pipes soon, or before the water in the boiler attains any great heat.

Saddle boilers consume as much fuel as most, and heat a comparatively small amount of piping; and the chief merit they have appears to be that they will stand any amount of abuse, and are not often out of order. There are boilers that will do double the work of a saddle boiler with the same quantity of fuel, and the various modifications of a saddle boiler are as ineffective as the original. To notice all of them would take up more space than the boilers themselves, and that is not little, and yet yield no practical matter.

Of HORIZONTAL BOILERS, Thomson's retort is one of the best; Monro's cannon being a modification of the retort principle. The former is not so complicated as the latter, therefore not so liable to get out of order. The retort exposes double the surface that a saddle boiler does to the action of the fire, holds little water, heats quickly, consumes any kind of fuel, and requires but little attention. The cannon boiler is equally good, only being more complicated it is more liable to get out of repair; but then its complication is an advantage, for it is much more economical to replace a part than the whole of a boiler. A leaky joint is soon stopped, but who can stop up a crack in a clumsy monstrosity cast in one piece? I consider complication so far an advantage rather than a drawback.

With a boiler of many parts there may be defects. I admit there are, for it not infrequently happens that a part is not in unison with its neighbouring parts—a flaw or a defect is there or results; but how much easier is it to put in a new part than remove the whole.

Another merit of a horizontal boiler is that it takes less room to set, and can be used in many places where an upright boiler could not be fixed; yet, what with the soot or dust, the heating powers are considerably reduced and the draught is usually sluggish.

I will not criticise all boilers, for some of them have nothing to recommend them, and I have no doubt that any serviceable old boiler excelled its contemporaries at some time. A good thing to-day may be a very poor affair to-morrow, and a good boiler now may be a very bad one in the next generation.

UPRIGHT TUBULAR BOILERS owe their origin to Mr. J. Weeks. I cannot see any great difference between the upright boilers of the various makers, and I would just as soon have one as another. Ormson's is a deviation from that of Weeks, and is said to expose no joint to the direct action of the fire. There may be merit in that; but experience tells me that a joint will not leak an hour sooner by being exposed to the action of the fire than when not exposed.

One principle prevails in all tubular boilers, and the only difference I can see in them is more technical than important. Weeks' improved tubular boiler is as good as any, though I am a little partial to Clarke's upright with the water-jacket at the bottom, which I consider a move in the right direction. Boiler furnaces heat too much brickwork; but if the water-jacket were made to enclose or confine the fire the entire length of the boiler, only allowing a flue-hole at the top, or two flue-holes if the boiler were large, and then bringing the flue round the water-jacket on the outside, I think very little heat indeed would be lost; but, as it is, fully one-half the heat is lost in the brickwork and in the chimney.

Everybody is acquainted with a tubular boiler, therefore I need not describe one; but I will treat of Weeks' improved as being the one with which I am practically most acquainted. Having the size No. 4, costing £20, in use, I have experience of its working.

Weeks' improved boiler has one four-inch flow and two four-inch return pipes, or apertures for pipes. The return-pipes do not pass through any hot brickwork, therefore the water comes into the grate-bars, which are hollow, and placed, of course, horizontally. At each end of the grate-bars is a box-like pipe to which the pipes of the grate are connected, and at the end opposite the furnace-door, where the return-pipes enter the boiler, is a six-inch aperture through which the heated water from the grate-bars passes into the upper part of the boiler, where there are two circular ring-like pipes of a hexagon shape, against which the heat of the

fire is mainly directed. Into these circular pipes round pipes are fixed, and connected at top with a circular basin, at the upper side of which the flow-pipe is situated. The boiler proper is 3 feet 6 inches high, and with the grate-bars about 5 feet high. It is about 3 feet wide at bottom, and tapers to about 2 feet at top. The grate-bars with the end-junctions are 3 feet 6 inches long, and they are placed so that the side pipes are 6 inches higher than the centre pipes or grate-bars.

There is not a part about this boiler on which the fire does not play, and, as a necessary consequence, the full heating power of the fire is employed in heating the water it contains. Owing to the parts being narrow and circular, the surface exposed is large; for, unlike a saddle boiler on which the fire can only act on one side at once, in a tubular one all the surface is simultaneously exposed. Thus a £20 saddle has only some 25 feet of directly exposed surface, and the same of indirect; but Weeks' improved £20 tubular boiler has, when in full going order, over 100 feet of directly exposed surface, and no indirect of any moment; but at times, when the grate-bars are covered with ash, and the feeding cavity full, a certain amount of indirect surface presents itself. On the other hand, we do not allow anything for the under side of the grate-bars, though boiler-makers generally include them in their calculation. I consider that a tubular boiler having 150 feet of exposed surface will have at all times on an average—making allowance for the accumulation of ash on the grate and the coke in the feeding cavity—70 feet of direct and 30 feet of indirect surface exposed to the action of the fire, and this gives $70 \text{ by } 50 = 3500$ gallons of boiling water, to which we add the 30 feet of indirect surface $30 \text{ by } 10 = 300 + 3500 = 3800$ gallons of water as the heating capabilities of the boiler. But this is more by 50 gallons than Messrs. Weeks calculate their boiler to heat. Well, but one of my neighbours has a No. 3 boiler of Weeks' heating 800 feet of four-inch pipe, whereas it is only calculated to heat 600 feet. The boiler, however, in severe weather has to be pushed, and tubulars never ought to be overworked. Mine, on the other hand, has only some 1200 feet of piping attached to it, one-third of which is $\frac{1}{2}$ -inch, and this enables me to fire easily and the boiler to play with its work.

In the severest weather I can have boiling water in the pipes in an hour after lighting the fire; and now I can run water round a vinery or any house in ten minutes by merely turning a valve, whereas had I nothing but a saddle boiler the fire would be to stoker or light, and if boiling water were had in a couple of hours I should think myself well off. All I have to do is to clean the boiler in the morning, or rather the furnace, and feed it. This takes up about half an hour, for I like to leave all about a boiler as tidy as a well-swept parlour, and not have ashes in a corner of the fire-hole, and coke thrown about everywhere. The draught is left open until the houses are attended to, or say half an hour, and then closed entirely, and no one can find the fire more than warm after that; but the fire burns, keeps the pipes hot until six o'clock in the evening, when the fire is made up for the night, occupying about ten minutes, and I rarely see it again until morning in mild weather. But in severe weather, when I have all the houses going, I give about half an inch of draught in the morning until 1 p.m., when the fire is raked, more coke added if necessary, and the draught reduced to nothing. At 6 p.m. the furnace is again raked, refilled with coke, the draught-door opened about a quarter of an inch if the night is likely to be severe, or shut if likely to be mild. The boiler wants no further attendance until morning unless a sharp frost occurs, when a little more draught is given before going to bed, and then we can sleep with a conviction on our minds that our charge is as comfortable as ourselves. Compare a saddle boiler to a tubular, and deal practically with both, and we shall find a vast disparity between them. One does as much more work as the other with the same quantity of fuel, and in other words saves the proprietor's pocket, and contributes largely to the gardener's ease of mind and body. I hold that anything and everything in a garden is or ought to be fixed on that principle; and I consider that if a gardener can save his master's pocket by an increased outlay, that it is better than letting money lie dormant. Although a tubular boiler conforms to every

point but one, it has as regards that one—viz., point 9th, a serious defect—it only burns coke well.

In respect to a boiler on a new principle, I have a notion that a series of circular tubes would be better than upright tubes. Presuming the lower circle of pipe to be 3 feet in diameter, the next would be 2 feet 9 inches, and connected to the other or lower pipe by four joints of the same diameter as the pipes. These circular and short uprights being six-inch, and an inch between would give a number of coils, and these coils would gradually be reduced in diameter so as to be 1 foot 6 inches at the top of the boiler. Around the whole I would have a water-jacket, and so formed as to suit the pipes; for the fire, after striking the circular pipe, would branch out in two directions—one towards the jacket, and there I would have a concave cavity to receive it, and so arrest its hurried passage upwards, and this being continued the length of the boiler would well nigh exhaust the heat of the fire.

I would have the firegrate-bars hollow, and connected to a circular six-inch pipe, into which the return-pipes would enter from two opposite points, on which the water-jacket would not only rest but be connected. The hot water from the jacket and that from the boiler would meet together at the top of the boiler in a circular basin, but flat at the bottom and top, and with a four-inch aperture in the upper surface for the flow-pipe. In a large boiler of such a form there would be a series of coils, and the fire would strike against the boiler from the bottom to the top, and that alone would double the rapidly heating power. Such a boiler would hold a large quantity of fuel under it, the whole or part of which fuel could be made to act by increasing or diminishing the draught. Lastly, it would present a larger extent of surface to the action of the fire than any boiler at present made, and certainly would take less fuel to heat it.

I have now only to add that every boiler should be under command like a horse; and I cannot refrain from saying that dampers are not the sort of contrivances for regulating a boiler. The regulator ought to be the ashpit door, and by opening or shutting it the draught should be increased or decreased at pleasure.—G. A.

VINES BREAKING AGAIN SOON AFTER BEARING A FORCED CROP.

From my early Vines I cut the Grapes at the end of April and close of May. The Vines were turned out and pruned early in June, and tied to stakes in front of the house. I thought they were at rest, but on examining them to-day (July 23rd) I see the buds are very plump, and swelling very fast. They seem to me as if they were asking to be taken again into the house. It now has succession Pines in it. The Vines were taken into the house on the 13th of November last year, to start them, and that was a month earlier than before. I should like to take them in now if you think I should be doing right. They are Black Hamburghs and Sweetwaters.—A YOUNG GARDENER.

[We think you pruned your Vines too early, and if exposed to heat and moisture the roots would cause the buds to swell. In such a case, as there is no likelihood of frost to injure them, we would let the Vines remain outside until the buds were broken, and their shoots were from 1 to 2 inches in length. They will break more regularly than if placed in the house, and then they will be early enough to enable you to have the Vines in bloom in bright weather.]

LANDSCAPE-GARDENING IN IRELAND.—In our last we announced the death of Mr. Fraser, so many years the leading landscape-gardener of Dublin; and it is with pleasure that we see his place is about to be occupied by a gentleman so eminently worthy to follow in his footsteps. By an announcement which appears in our advertising columns this day, we observe that Mr. Chapman, of Richmond, in Surrey, has determined upon opening an office in Dublin, and devoting himself to the interests of landscape-gardening in Ireland. From our own knowledge of Mr. Chapman and of his antecedents we augur for him a successful career. A pupil of Sir Joseph Paxton's, and for several

years an assistant to Mr. Kemp, he has so imbibed the ideas and principles of these masters as to leave no doubt but that if he is spared, and he receive that patronage that is his due, Ireland will not regret that he has chosen to number himself as one of her adopted sons.

SOME OF THE GARDENS WORTH VISITING IN YORKSHIRE.

I AM sure the list you purpose giving of the chief gardens in Great Britain will be a great boon to the tourist as well as the gardening community, and according to request I send you a list of a few places in Yorkshire that are well worth a visit; also, the nearest town or railway station.

Place.	Proprietor.	Gardener.	Town or Railway Station.
Castle Howard...	Earl of Carlisle	Mr. Sutherland	Castle Howard Sta.
Harewood House	Earl of Harewood	Mr. Fowler	Leeds. Arthington Station.
Studley Royal	Earl de Grey & Ripon	Mr. Clarke	Ripon Station.
Upleatham Hall	Earl of Zetland	Mr. Grey	Redcar. Marske Station.
Bishopthorpe	Archbishop of York	Mr. Onlston	York.
Duncombe Park	Lord Feversham	Mr. Gower	Helmsley. Gilling Station.
Eserick Hall	Lord Wenlock	Mr. Mitchell	York.
Grimston Park	Lord Londonborough	Mr. Richards	Tadcaster. Stutton Station.
Everingham Park	Lord Herries	Mr. Links	Market Weighton.
Allerton Park	Lord Scourton	Mr. Saul	York. Allerton Sta.
Baldersby Park	Lady Downes	Mr. Mallorie	Thirsk. Baldersby Station.
Kilnwick Percy	Hon. Adml. Duncombe	Mr. Campbell	Pecklington.
Setton Hall	"	Mr. Campbell	York. Tollerton Station.
Benningborough	"	"	"
Hail	Hon. Payan Dawne	Mr. Foster	York. Skipton Sta.
Ripley Castle	Sir Wm. Ingleby	Mr. Fowler	Ripley.
Temple Newsam	Meynell Ingram, Esq.	Mr. Taylor	Leeds.
Thirsk Hall	F. Bell, Esq.	Mr. Davidson	Thirsk.
Heslington Hall	J. G. Yarborough, Esq.	Mr. Davidson	York.

Should you at any time publish the above list separately, I shall be happy to be a subscriber to the work.

I hope the Gardener's Benefit Society, which has been so ably advocated in your paper, will soon be established. I shall be happy to send you half a dozen gardeners' names, as members, as soon as the conditions or rules are published.—C. S. G.

BERBERRIES AND THEIR CULTURE.

THE genus Berberry yields to no other shrub in beauty, whether we regard the foliage, habit, or flowering properties. The foliage is peculiar in shape, of a bright glossy green; the habit is compact, and the flowers produced in profusion, of a beautiful yellow colour, and are followed by berries which make the plants handsome for a long period.

The common Berberry (*Berberis vulgaris*), is a native of this country, and is found in hedgerows and on wooded hills, where its fruit has refreshed many a rustic's palate. The flowers are produced in yellow racemes in April and May, are offensive to the smell if closely approached, but at a short distance their fragrance is very grateful. There is something very singular about fertilisation in a Berberry flower. The stamens are bent back to each petal, the concave tips of the petals sheltering the anthers. Watch a bee come and dart its proboscis into the flower, sipping the nectar from the bottom of the cup where the filaments join the ovary; and immediately any filament is touched near the ovary, the stamen springs from the petal and shakes the pollen on the stigma. A pin or hair similarly brought into contact with the lower part of the filaments next the ovary produces the same result, but no shaking of the branch, nor any pinching or touching of any part of the flowers exteriorly, has any effect on this irritable flower. The fruit, about the size of a pea, succeeds the flowers, and when ripe makes an excellent preserve if one quart of fruit be boiled along with 1 lb. of loaf sugar. In its raw state the fruit is cooling and agreeably acid, and its juice is used for flavouring sweets, and in a dry state for making sugar plums. The bark of the tree is used by many old women, even at this day, as a cure for jaundice and affections of the liver.

Berberis vulgaris and its several varieties—viz., *violacea*, *alba*, *nigra*, *asperma*, *lutea*, and *purpurea*, all named after the colour of their fruit, thrive in almost all soils and

situations; but deep, rich, sandy loam suits them best, and an open sunny site or aspect is necessary to secure fruit. In woods, however, where the shrubs receive a moderate amount of light without much sun, I have seen them plentifully producing fruit which seems to be well relished by some of the feathered tribe. As we begrudge a few Cherries and Strawberries for the songsters' invaluable nine-months picking of grubs out of our gardens, is it asking too much to request that a few Berberry shrubs be planted in the woods? They are an excellent cover for game. Nevertheless, their fruit grown in shade is never so highly flavoured as when exposed to sun heat, light, and air; therefore, I by no means recommend planting Berberies in woods in hopes of obtaining their berries to increase the novelty of the dessert, and fill the preserve-jars in the store-room. Still the fragrance of the flowers imparts a charm to the woodlands in spring, and may help to keep the songsters from the netted Cherries.

As a hedge plant the Berberry has a few points to recommend it. It will bear any amount of cutting, grows rapidly and close, and is rather rough to face, its short prickles or spines not being pleasant. It is not so good, however, as a Quicksset (Thorn) hedge, and at the very best is but a second-rate hedge plant. Yet, whatever good properties it might have, I fear ignorance and prejudice are still too prevalent to acknowledge as erroneous the popular idea that it communicates the mildew fungus to the Wheat plant. Not long ago a certain M.D. drew my attention to a field of Wheat infested with a parasitical fungus, and in walking round the garden a few days afterwards he noticed a fungus on a Berberry apparently identical with one on the Wheat plant in the field adjoining. He was a good fungologist, therefore I was mute; but he told such an old-wife tale about the Berberry communicating blight to Wheat in close proximity to it, even insinuating that it had the power to cause Wheat to be affected by the Berberry blight at a distance of 200 yards, that I very soon doubted his words, for I had seen abundance of blighted Berberry shrubs in a plantation adjoining a Wheat field which did not prevent the Wheat plant yielding sixty bushels per acre. We had a dispute, when out came the microscope; and Greville's cryptogamical work decided the fungus on *Berberis vulgaris* to be *Æcidium berberidis*. Subjecting that on the Wheat plant to a power of 300 diameters the first glance was enough to show a difference in the two fungi, identified at once as *Puccinia graminis* by my scientific friend, who never kept his microscope, nor books, nor accumulated information out of the reach of a poor man.

Irrespective of its claims as a hedge plant, in which respect it about ranks with the Privet, it will be admitted on all hands that the Berberry is a highly ornamental shrub, whether planted in large shrubberies or by the side of woodland walks. Besides its peculiarly ornamental character it is of easy culture, requiring but little care after first planting.

Berberies may be best treated of in two classes—the deciduous and the evergreen.

DECIDUOUS SPECIES.—Of these *Berberis vulgaris* is the type. They are suitable for woods, where they form, as mentioned before, a capital cover for game, and for large shrubbery-borders; but they are not suitable for planting in groups on lawns, for there plants should be as ornamental in winter, for the most part, as in summer, and this the deciduous character of these Berberies in a great measure prevents.

In planting them in shrubberies, it is necessary that the ground should be trenched deeply without turning up too much of a clay subsoil; and if that be wet, drains should be cut 4 feet deep and 21 feet apart, with a suitable fall and outlet. If the ground be poor, a liberal dressing of manure or leaf mould will contribute much to the prosperity of the shrubs; and a barrowful of fine, but not very rich, soil put a little under, around, and on the roots at the time of planting will materially assist the plants to form fibres and roots, and give them a start.

Half the height which any shrub attains is the proper distance to plant from a walk, and its full height the distance from plant to plant in the shrubbery. Most shrubberies, however, are faced with some of the under-shrubs, or lower-growing kinds: consequently the taller kinds may be planted

at a greater distance from the walk, so as to allow of those of low growth being planted in front of the border, so that, even when of full size, they will not need cutting back or clipping to prevent their encroaching on the path or space beyond their limits.

Every tree or shrub should be planted at such a distance that it will never be made by crowding to assume an appearance contrary to its natural habits.

Were I forming a shrubbery I would have no duplicates in it, for no amount of beauty can be pleasing unless it be varied. Shrubberies of the present time have no beauty beyond that seen at first sight, for such are mostly composed of the commonest shrubs purchasable, and have nothing to recommend them beyond cheapness, which is not commensurate with the interest lost. Were no duplicates admitted the shrubbery would afford an interesting field for study at all seasons, and take hours instead of minutes to inspect before all its beauties could be noticed.

I would distribute shrubs in mixed shrubberies, so as to present a good face to the eye; but, at the same time, with a variable yet harmonious aspect. But were the place large I would plant each natural order in groups, after the style of an arboretum; and with a view to this I would place the Berberideæ in the foremost rank. A group of Berberies on a lawn would be a beautiful object in May when our flower gardens are little better than fallow fields, and highly ornamental in autumn from the effect produced by their berries. Disposed of in that way, I should plant the deciduous kinds in the centre of the group and the evergreens chiefly around them, always taking into consideration the height of each species and their character of growth. I should not plant a straggling grower in front, but put it behind a compact grower.

In planting, however, the ideas of individuals vary. Some would object to planting deciduous shrubs and evergreens together in groups, and it certainly detracts much from the beauties of evergreens when they adjoin deciduous trees, especially when seen on the same level with them: therefore I would only employ evergreen Berberies for groups on lawns, unless I were forming an arboretum, when I might plant the deciduous and evergreen together.

PROPAGATION.—Seeds of the common kinds, deciduous and evergreen, may be sown in sandy loam, in the open ground, on nursery-beds in March or April, covering them with fine soil about half an inch deep; but seeds of the evergreen species, as *Berberis Fortunei*, *nepalensis*, &c., should be protected in a cold frame until the seedlings are fairly up, and when of sufficient size to handle transplanted into nursery-beds, and afterwards further transplanted annually or biennially, allowing more room each time between the plants, until they are of sufficient size to plant out finally.

Seedlings are such a long time before they flower compared with plants raised from layers, division of the root, or suckers, that it is not a very advisable method of propagation.

The deciduous species are best raised from layers, and the evergreens by suckers, with a portion of root attached to each when taken from the parent. Layering may be done any time whilst the plants are at rest; but about this there are many opinions. Some will insist that it ought to be done when the sap is descending, for then a callosity is sure to be formed; but others uphold that it is best done before the sap rises, for the plant emits fibres more rapidly then than at any other period, and a tongued branch is more likely to callus at that time than when the plant is all but at rest. I find spring the best time for layering and getting plants of any kind to root quickly; but in the case of the Berberry it is immaterial what time they be layered, if tongued like a Carnation to facilitate the process, and pegged securely under the surface, leaving the slit open, and allowed to remain attached to the parent plant for twelve months from the date of the operation. The layers then may be detached from it, taken up with as much soil as will adhere to the fibres without falling off, and planted either in beds to gather strength, or at once into the places where they are to remain.

Division is simply taking up an old plant and slipping the side shoots off with as much root adhering to them as possible; or digging round an established plant, and so opening

a trench, and then taking off the suckers without disfiguring the parent or checking its growth so much as lifting would. These suckers are planted in lines, three in a four-foot bed, and the plants about a foot apart in the line, more or less according to their size, from whence after a couple of years' growth they are transplanted to their final quarters.

After planting, deciduous Berberies require very little management. The shrubbery should have the weeds kept under, never allowing them to seed, and be slightly hoed and raked over at least twice during the summer, besides any weeding that may be required, and a general clearance of decayed wood and leaves after all the latter are fallen. When hard frost prevails, a couple of inches of decayed leaves or other vegetable matter thrown on the surface will materially increase the health of the shrubs; and however much the flower-beds may require a little of this vegetable earth I would not forget to let the shrubs have the decayed remains of the leaves taken from them the year before. I object to digging amongst shrubs at any time, especially when the roots nearly occupy the whole of the ground, and are close to the surface. The surface roots of shrubs are of as much moment to their wellbeing as those of a Vine are to successful Grape-growing. Transplant a tree every year, and it becomes a dwarf; and shrubs in like manner, robbed of their roots annually by surface-digging, become stunted. Pruning must be limited to cutting-out irregular growths and such as overlap each other, as well as any dead wood that may be found. Should any shrub become unsightly it may be cut down; but if the plant be very old it would be better to stub it up and plant a young one, having first renewed the soil.

EVERGREEN SPECIES.—These are suitable for beds and groups on lawns. In either case the ground should be dug deeply, and a liberal amount of leaf mould or well-rotted stable-manure added, and if the turf has to be removed it should be turned in. Turf, however, makes such a nice compost for plants, pot Vines, Pines, &c., that few gardeners can resist the temptation to rob the intended occupant of the bed of its due share of decayed vegetable matter by taking the turf away to the compost-heap. Turf is so difficult to come at in most places, that we can hardly insist on its being dug into the new bed; but still, every barrowful of turf taken away is equal to a barrowful of dung, or two of decayed leaves: therefore, for every barrowful of turf removed the same quantity of vegetable matter should be returned to the bed.

Where the ground is of a clayey nature the soil should be taken out 18 inches or 2 feet deep, and its place filled with a compost formed of two-thirds rich loam and the remainder leaf mould with a sprinkling of river sand. In digging-out this hole or bed another point must be taken into consideration: Can the water escape readily through the bottom of the bed so as to prevent stagnant water lodging? If not, a drain must be cut to take away the water that will filter to the bottom, and where, unless there be a drain to carry it off, it will very soon cause the shrubs to assume a sickly appearance. Without drains in clay soils, beds dug out a couple of feet deep are little short of a swamp during the greater part of the year, and the last plant to put in such beds is the Berberry, for like the Sikkin and Bhotan Rhododendrons they are all natives of the hills, where the rainfall is large, but the substratum of the soil of such a nature that no water can lodge so as to become stagnant.

Evergreen Berberies are better planted in early spring, but any time from the middle of October until April will answer; and even they may be removed in summer immediately after flowering, when it is possible to take up with a ball, and water freely for some time after planting. They may be planted in groups on lawns without any preparation of the soil, but then, unless the soil suits them they will do anything but thrive.

Whether in groups or in beds they need little pruning, which should be confined to cutting-in straggling growths, and such as are weak and old. The beds should be kept clear of weeds and leaves, and raked roughly occasionally to prevent moss forming on the surface. A dressing of leaf mould will tend to increase their vigour, and if it be pointed-in with a fork the bed will have a neat appearance during winter. The leaf mould may be put on any time in the autumn.

Some of the evergreen varieties make handsome pot plants; in fact, all the evergreens are useful grown in that way, either to ornament the conservatory in spring, or to plunge in the flower-beds in winter, where their evergreen character is more beautiful than red brick, no matter how fine the tracery, and their rich yellow flowers impart a charm in spring to an otherwise anything but garden-like object.

I by no means deprecate the present rage for flower gardens, but I wish to see them more like a garden in winter and spring than many are at present. Mr. Beaton (the loss of whose pen every amateur and gardener deplores whilst sympathising for his affliction), the father of the massing system, had shrubs of low growth to succeed the gaudier summer occupants, with other spring-flowering plants, to give at least an interesting character to the beds during winter and spring, if not a good display at the dull and reviving seasons. If a garden be worth having fine in summer, it surely is worth making interesting in winter. The evergreen Berberies are so beautiful, compact, and low-growing, as to fit them for an honourable position in any arrangement of plants required to be interesting in winter and spring.

The following list includes some of the best species, most of which are of a highly ornamental character.

Those marked thus * bear fruit, which makes excellent preserves; and evergreens are indicated thus †. The others are deciduous, or their foliage becomes so much browned in winter as to be not suited for beds.

* <i>Berberis vulgaris</i>	8 feet ...	England.....	April and May.
* <i>vulgaris violacea</i>	8 feet ...	England.....	April and May.
* <i>vulgaris alba</i>	8 feet ...	England.....	April and May.
* <i>vulgaris nigra</i>	7 feet ...	Europe	April and May.
* <i>vulgaris purpurea</i>	6 feet ...	Europe	April and May.
* <i>vulgaris lutea</i>	6 feet ...	Europe	April and May.
* <i>vulgaris asperma</i>	6 feet ...	Europe	April and May.
* † <i>dulcis</i>	8 feet ...	Austria, Magellan.	May.
* † <i>canadensis</i>	6 feet ...	Canada	April and May.
* <i>sinensis</i>	4 feet ...	China	April and May.
† <i>aristata</i>	6 feet ...	Nepaul	April and May.
† <i>fascicularis</i> (<i>Mahonia</i>)	8 feet ...	California	April and May.
† <i>ilicifolia</i>	4 feet ...	Terra del Fuego	July.
† <i>Wallichiana</i>	4 feet ...	Nepaul	May and June.
† <i>heterophylla</i>	4 feet ...	Magellan	May.
† <i>trifoliata</i>	4 feet ...	Mexico	April and May.
† <i>nepalensis</i>	5 feet ...	Nepaul	May and June.
† <i>asiatica</i>	4 feet ...	Nepaul	May and June.
† <i>empetrifolia</i>	3 feet ...	Magellan	April and May.
† <i>dealbata</i>	6 feet ...	Mexico	April and May.
† <i>Darwinii</i>	5 feet ...	Mexico	April and May.
† <i>Fortunii</i>	5 feet ...	China	April and May.
† <i>Leschenaultii</i>	5 feet ...	China, Neilgherries	April and May.
† <i>intermedia</i>	4 feet ...	China, Neilgherries	April and May.
† <i>japonica</i>	4 feet ...	Japan	April and May.
† <i>glumacea</i>	4 feet ...	Japan	April and May.
† <i>Bealei</i>	4 feet ...	Japan	April and May.
† <i>crassifolia</i>	4 feet ...	Japan	April and May.
† <i>diversifolia</i>	4 feet ...	Japan	April and May.

In addition to the above, there are *B. tinctoria*, Hookeriana, Janiesoni, Neuberti, trifurca, umbellata, and tenuifolia, chiefly from Nepaul, all well worth looking after, and several more in the great nurseries undergoing a period of probation, and I hope some correspondent will give us a brief description of them, with hints as to their cultivation.

The *Mahonia aquifolia* is so closely allied to the Berberry, that I cannot refrain from noticing it. It is second to the Laurel only in usefulness, and yields to no evergreen under-shrub in the beauty of the flowers in early summer, and its beautiful purple berries in winter; these are produced in far greater abundance than those of the common Berberry, and make quite as good a preserve. Planted in woods it affords one of the best, if not the very best, cover for game. On a lawn it makes a good bed or group, and in shrubberies and by woodland walks it is quite at home. The treatment recommended for evergreen Berberies suits it, but it will thrive in nearly all soils and situations without any trouble beyond planting.—GEORGE ABBEY.

SLUGS ON STRAWBERRIES.

In reply to your correspondents, who inquire the best means of protecting Strawberries from slugs, I would advise them to act in pursuance of the old adage, "Remove the cause," &c., by making one or two sowings of sifted air-slaked lime over the beds, and, indeed, over the whole garden; for I have never found it injure even the tenderest

seedlings when used in moderation early in spring. The best time for performing the operation is on a mild damp evening. Choice may be made of such following several dry days when the slimy race are sure to be depasturing in great force. By repeating this operation a garden may be entirely cleared of them.—G. E.

FROST OF JULY 19TH—LAYING DOWN Turf.

THE frost of July 19th was very severe at this place (Desborough, Northamptonshire); all Potatoes not protected by fences were severely injured, quite as much so as on the night of May 1st. A crop of Buckwheat I had growing in an exposed situation was almost entirely destroyed.

I should feel obliged for any information as to the best way to lay down a moderate-sized lawn.—H. H. C.

[If you can obtain turf from a nice pasture with a fine sward upon it, and free of Daisies, Buttercups, and Plantain, we should prefer turfing to inoculating, or sowing with a lawn-mixture of seeds. Should the turf at hand be good, having a sprinkling of Suckling Clover in it, but not sufficient to turf the whole, you would do well to inoculate, tearing the turf into pieces about 3 inches in diameter, and placing them 6 inches apart in quincunx arrangement, and then strewing over all a few pounds of lawn-seed mixture. Do this in showery weather in April, and you will have a finer lawn than from turfing, and one not half so liable to become brown in summer. But if the turf at hand is coarse and full of weeds, seeds will serve your purpose better than turfing or inoculating, for nothing is so ugly as a rubbishy lawn, and no finer ornament exists in gardening than a lawn of fine grasses well kept. Early in autumn, not in winter, and in February and March, are good times to turf and inoculate, and the latter part of August and September, March and April, to sow lawn grass seeds.]

PREVENTION OF MILDEW ON VINES, PEACHES, &c., IN ORCHARD-HOUSE.

My vineries and orchard-house have been quite free from this disease this season, a very simple method of prevention having been adopted. Take the upper end of a worsted stocking, tie up in it some very dry sulphur powder, and fasten it to the end of a long stick. About three times a-week, in the daytime, shake this bag of sulphur. The house will in a few minutes be filled with a fine dust, which settles in an almost imperceptible form on every leaf, and this is quite sufficient to act as an antidote to fungi.

The health of all my vineries has been perfect; the fruit of the largest size and the finest quality. This day my gardener has gathered thirty-one dozen of Peaches and Nectarines of the best quality from the large orchard-house, besides many dozen of inferior size, completing upwards of sixty dozen of Peaches and Nectarines within the last four days.

The ventilation of my houses being perfect, as far as anything can be perfect, the flavour of the fruit is excellent. In my orchard-house I have gathered Peaches this season measuring from 9 to 10½ inches in girth.—A CONSTANT READER.

HARDY DECIDUOUS TREES.

(Concluded from page 72.)

THE SWEET CHESTNUT is certainly not so widely spread as the Elm, Oak, and Beech, and it is questionable whether it is really an indigenous tree or not. It is, however, one to which public attention has often been directed, some of its admirers giving it all the qualities of the Oak. This is more than questionable as a timber tree; but as one for ornament it is scarcely, if at all, inferior. The dark glossy green of its foliage, with the numerous spikes of bloom by which the adult trees are studded in August, give it quite an interesting appearance. The single tree always shows a wide expanse of top, and as an avenue tree, it has few superiors. It, however, only thrives on dry, stony, or sandy

ground, and in such a place its growth is as rapid as the Beech. It attains nearly if not quite the same dimensions—perhaps will exceed that tree when the specimen becomes old enough. Some noble trees in the park at Preston Hall are upwards of 17 feet in circumference at 5 feet from the ground, and they appear quite sound and healthy, and likely to increase in size; but there are not many spots which suit them so well. In many places the tops begin to die, and decay sets in at the collar before they attain anything like the size above stated; while for cold or damp situations they are totally unfit. Perhaps one of the best purposes they are put to is for coppice, the poles being the most durable that can be had for hop-poles; and in suitable places the tree grows as freely as anything that is planted. As a timber it resembles Oak, but is too liable to split when cut up for use in carpentry. Longitudinally it is tough and strong, while transversely there is not sufficient adhesion between the layers of each year, and the consequence is that when it is sawn up pieces splinter off.

SYCAMORE is a hardy tree, growing freely in most situations, and very often where scarcely any other will live. As a single tree it withstands the wind well; and while we see most trees bending or leaning in one direction in accordance with the prevailing high gales, the Sycamore rarely shows any difference. It also withstands the sea-breeze as well as most trees. It likes good ground, grows rapidly and to a large size, and rarely dies off. There is in Cobham Park a very fine tree of this kind which is connected with some historical event; the girth near the bottom I believe to be nearly 22 feet. The soil it is growing in is dry, though not particularly so, and it is also tolerably deep. As a single tree the Sycamore affords more shade, perhaps, than any other, the large leaves thickly clustered together tending to make the Sycamore more dense than any other. Its leaves, however, become blotched during summer, and fall short of the clear dark green hue of the Sweet Chestnut.

THE LIME is, perhaps, the quickest-growing tree we have on ordinary soils, and when young it will even excel the Elm. It makes an avenue quicker than anything else, and, being very hardy, rarely suffers a mishap. There are fewer branches blown off the Lime than most other trees, and the number of avenues of it are too well known to require comment. Its lower branches hanging on the ground give it a cool shady character, while the aspect of the tree is anything but one of solemn gloominess.

OF THE ORIENTAL PLANE I wish I could say something more favourable, as its appearance at times is all that can be desired; but some excellent specimens we had of it here became much diseased some years ago, and several have died, while the others have dead tips and other appearances of ill health. It is also a tree of foreign growth rather than indigenous, and less likely to become an aged honourable member of the sylvan community. When healthy it looks well. The foliage is more clear than the Sycamore, the latter being rarely without black spots.

THE ASH is a sturdy native, presenting, perhaps, greater diversity of form than any other tree; but for park scenery it is certainly not held in such high esteem as many others. It is, however, not by any means in consequence of its lacking due proportions that it is less esteemed. The name, perhaps, has a something to do with it. Some little time ago I measured one in the park at East Sutton that was upwards of 22 feet in circumference at 4 feet from the ground. Its top was also in proportion.

THAN THE WALNUT perhaps no tree, with the exception of the Oak and Yew, has a more venerable appearance when stricken with age. The hoary whiteness of the bark, with now and then the fracture not healed over where a limb has been blown off, gives the Walnut a fine appearance. They are, however, better adapted for a group or for single trees than for an avenue. The diversity of their growth renders them unsuitable for that purpose. They like a good soil, not wet and yet not very dry. One of the best fruit-bearing trees I ever knew was in Northumberland.

OF THE beauty of THE HORSE CHESTNUT while in flower much has been said, and certainly it does then look well. The growth and outline of the tree is also good, but the foliage is not the best. It is, however, a favourite with

many people, is of rapid growth, and not particular as to soil. It is, however, liable to have large limbs blown off in summer—even young trees are sometimes almost split in two by fractures in this way.

THE LOMBARDY POPLAR forms an important feature in the landscape of many places; but it is certainly not of quicker growth than the Black Italian, which seems to outstrip anything it comes in contact with. For planting occasionally in formal belts they help to break the outline, and as such are very useful; but they are hardly wanted in dressed ground, nor even as single trees in a park, although some in Lord Torrington's park at Mereworth, in Kent, look well, having attained an extraordinary height. The White Poplar has little to recommend it.

There are many other deciduous trees of more or less merit. The Maples at times attain a good size; Hornbeam seldom grows so large as the Beech. An old Thorn is as noble a park ornament as anything that grows, and now and then a Willow attains to the goodly proportions of a timber tree. Its downy white leaves, turning with the breeze, contrast strongly with the hues of the other trees by which it is surrounded. It is not fair to enter the dressed ground for specimens fitted for outside work, or we might find large Tulip trees, Ailanthus, Liquidambers, and such like; but these are not English trees, and must await a notice elsewhere. We must not, however, omit to notice the Birch, not for its size but for its singular beauty and its adaptability for those wild elevated positions where many other things would hardly live. Widely differing from this is the Acacia, a tree not by any means unsuited for park scenery, and requiring dry ground. The timber of this is, perhaps, as hard as any home-grown wood we have, but I am not prepared to say that it is so durable as it was expected to be when it was first introduced. It is, however, questionable whether it will ever become a long-lived tree; and, like the Horse Chestnut, high winds are liable to blow off large branches. Some other trees might also be mentioned here; but the above are the most important and useful ones.

In concluding the above hasty glance at our most important hardy deciduous trees, I hope some of our readers who reside in districts where specimens of remarkable size exist will be kind enough to forward to the Editors the dimensions of those trees, for large trees are certainly deserving of as much attention as large animals or large fruits; and the latter having had their due share of attention of late, let us try and do justice to the most ancient, most noble, and certainly the grandest productions of the vegetable world.

J. ROBSON.

PROPER STOCKS FOR GRAPE VINES.

THIS is a subject which, as it presents itself to my mind, has not received from cultivators the amount of attention which it deserves; and the object of this communication is not so much to relate my own experience in the matter, as to call the attention of others to it, and invite their co-operation with a view to discover by experiments the stocks on which the different varieties succeed best. Reasoning from analogy, there can be little doubt but that the Vine can be influenced both as to the quantity and quality of its produce by the stock it may be grafted on, as well as other fruit trees, and practically I have found this theory correct as far as I have been able to test it, as the following instances will show. When Snow's Muscat Hamburg Vine made its appearance I procured a plant of it, which I planted in a house along with Black Hamburg Vines. The latter have succeeded perfectly well, but I never had anything like a fine bunch on the Muscat Hamburg; the berries were unequal in size, the bunches loose, and not in any case much over a pound weight. Unwilling to give up growing a Grape which is, perhaps, the highest flavoured of all Black Grapes, I inarched it on Black Hamburg stocks during the summer of last year, and at the present moment I have six bunches on each of these inarches, the lightest of which will weigh 2 lbs., the heaviest 4 lbs., with full-sized equally-swelled berries. The next instance is of an unfavourable character. It is that of a Bowwood Muscat inarched on a Black Barbarossa; this retarded the ripening of the Grapes a month as compared with the same Vine

on its own roots. I might mention several others, but those two are enough to show that the stock has an influence on the produce of the Vine, and may induce all who have an opportunity to make one or more experiments and relate their results, and in this way much valuable information on an important subject may be obtained. As far as my own experience carries me I am disposed to think that the Black Hamburg is an excellent stock. I am also disposed to think that the Raisin de Calabre will prove a good one, and probably the Syrian. On such stocks I would expect the Frontignans and other tender Grapes to grow as freely as Hamburgs, but actual experiment alone can determine this. If some of our nurserymen would import such hardy varieties as the American Catawba and Isabella Vines, I think it very probable that they would prove valuable stocks for parts of the country where the soil is cold and the climate wet.—WM. THOMSON, *Dalkeith Park*.—(*Scottish Gardener*.)

THE CASTLE KENNEDY FIG.

I HAVE read with some interest the notice of this Fig in the report of the Royal Horticultural Society's Fruit Committee in your Journal of the 7th ult. I feel interested in this subject because I have had an opportunity of eating this Fig. I own, however, to some surprise at seeing its flavour reported as not first-rate. Of course I have no judgment that can be opposed to professional opinions, but I have often eaten good Figs, and do not remember tasting any of better flavour. Perhaps the large fruit sent up for exhibition might not have been so highly flavoured as those of an average size. It may, perhaps, be true that the original of this sort was a "Large White Genoa" some century and a half ago; but if so, the altered shape, size, and colour—and I venture to think flavour too—which it has acquired by so long a domicile in the "land of the mountain and the flood," should entitle it to a distinctive name; and if I were a Scot my feelings of nationality would, perhaps, lead me to insist upon the right of this fruit, by the ordinary laws of domicile, to the specific name of "Castle Kennedy." Not being a Scot, I content myself with the hope that the knowledge of this Fig will not any longer be confined north of the Tweed; and if its cultivator, Mr. Fowler, should read this letter I trust it will induce him to send a larger assortment to some future Exhibition, and thus show our southern cultivators that if they want a really first-class Fig they have but to cross the border for one, and induce them to give southern Fig-admirers an opportunity of forming their own judgment.—A CONSTANT READER.

GROWING TOMATOES UNDER GLASS.

IN the absence of more full and definite information as to the exact conditions under which a correspondent, Mr. Fisher, has failed in getting a crop of Tomatoes in his Peach-house, I would suggest that the want of success may arise from either of two causes, or from both combined.

In the first instance, if they are growing in a shaded part of the house the absence of the necessary amount of light may cause an imperfect development of the fructifying organs.

In the next place, it is possible from their being so robust in growth the very same effect, to which reference has been made, may be produced by an undesirable development of leaves and young shoots, which crowds the clusters of bloom, and prevents the necessary action of light and air.

Either of these causes, or the two combined, are what may be suspected from the statement that the plants are much more vigorous and in better condition than plants which are fruitful in the open air.

Try what a closer imitation of the circumstances of the out-door plants will do to produce fruit in the strong plants. If they are full of large sappy leaves and young shoots, let such a proportion of both be removed as will fully expose the bloom to the sun and air, and cause the energies of the plant to be more concentrated to the blooms. At the same time let the plants be kept rather drier at the root.

This mode of proceeding will be likely to remedy the evil if it arises from the causes named, and is very commonly resorted to when the plants show signs of running to leaves and young shoots instead of being as fruitful as is desired; and as far as our own practice is concerned the pinching and disleafing has always proved successful when there was a disposition to barrenness.

The Tomato, as most gardeners are aware, can be most successfully cultivated under glass, and is generally resorted to in localities where the climate will not ripen the fruit when trained to a south wall. It is a good plan to let them attain a considerable size in pots before planting them out. Their being somewhat potbound for some time of course throws them into a fruiting condition, and there is little

fear of their becoming too stunted after being planted out. Such is not their tendency at all, but the very reverse.

For the production of Tomatoes early in the season there is perhaps no better way than that of growing and fruiting them in pots, unless, perhaps, where they can be planted out and kept warm all winter: then they become almost perpetual in bearing. When grown in pots seed should be sown in autumn, and they can be wintered in a cool dry stove, and shifted on in spring into 10 or 12-inch pots. They ripen their crop early in summer; but under all these circumstances it is necessary that they should be well pinched back as they make growth, and that they be kept thin of leaf, so that the blooms be not smothered-up.—D. THOMSON, *Archerfield Gardens*.

COLOCASIA ODORATA.

The fragrance of this species renders it a desirable subject in all collections of stove plants. The diffused odour, as it pervades the entire atmosphere of a hothouse in which the plant is blooming, resembles that of Mignonette; but the more powerful and concentrated fragrance which is experienced on nearer contact with the plant, is of the sweet aromatic nature of that of some Orchids. The *Colocasia odorata* is not a novel plant, but it is not common. It is one of the arborescent aroidaceous plants, which give such a tropical air to collections in which they occur. This species grows with a caudex of 3 to 6 feet high, and from 4 to 6 inches in diameter, and is then crowned at the top with a head of large, narrowly cordate leaves, supported on long stout footstalks, and traversed by prominent veins. The

flowers grow from the axils of the leaves towards the centre of the plant, and stand erect among the foliage. The spathe is about a span long, contracted below the middle, and then expanding into a concave or boat-shaped membrane, which at first stands erect, encircling the spadix, but ultimately bends over it like a hood. The spathe is green at first, but acquires a yellowish hue when at maturity. The spadix is club-shaped, and shorter than the spathe.

The foliage of the *Colocasia* is the seat of a waxy secretion, which, though scanty in the plants cultivated in our hothouses, is yet produced in considerable quantities when the plant is growing in its natural climate. The secretion is formed exclusively on the lower face of the leaves, and is confined to the axils of the principal nerves, where the cellular tissue produces it, and from which points this waxy substance extends sometimes over nearly the whole inferior surface of the foliage. In the cultivated plant it only exists in small scales, at the utmost not larger than the human nail.

A curious property possessed by the plants of this family, is the evolution of heat at certain periods of their inflorescence. This has been noticed by various observers, but apparently first by Lamarck, who, in 1777, made the discovery upon *Arum italicum*. The most exact experiments, however, are those of M. Adolphe Brogniart, made in 1834, upon a plant of the *Colocasia odorata*, which developed four flowers in the space of a month.

"The first flower began to expand on the 4th of March; but it was not till the 6th that the escape of pollen from its anthers commenced, and the increase of temperature on the spadix was perceptible to the touch. A very small thermometer, when applied to the flower, indicated a temperature in the air of 23° centigrade, while the spadix close to the fertile stamens, was 26°, and the club formed by the abortive stamens was 30°, the difference being 7°. The heat of the flower gradually diminished, and, in the evening, its temperature was the same as that of the stove. It is remarkable, however, that, while all the other Aroidæ that have been examined on this point, appear—when the heat has once disappeared,—never to regain it, the plant under consideration exhibited the same increase of temperature at

the same hour (2 p.m.) of the following day, and for four days it continued, although with gradually diminishing intensity, to present a similar phenomenon, when the flower finally faded.

"Another blossom having appeared shortly after, I adopted many precautions which should enable me to watch its progress. I procured a very delicate thermometer, applied it accurately to the most sensible parts of the flower; and protected the bulb by folds of flannel from the influence of the circumambient atmosphere, and by a purple shade from the rays of the sun. Another thermometer was suspended in the stove, not far

from the plant, to give the temperature of the stove. For six days a striking increase of heat took place in the flower, attaining its maximum about 4 p.m., and totally ceasing during the night and early morning. The greatest difference between the temperature of the flower and the general atmosphere of the stove, was 11°; and, as in the first blossom examined, so the central portion of the club of abortive stamens was the part which exhibited the heat most powerfully; next the base of that club, and then the stamens which were fertile."

The *Colocasia odorata* is a native of Pegu; is a free-growing plant under cultivation, and requires plenty of room both for its roots and leaves; the latter, indeed, it is which give to the plant its truly noble aspect.—(*Gardeners' Magazine of Botany*.)

STRAWBERRIES FAILING ON A CLAYEY SOIL.

I AM making a new Strawberry-bed, and shall be obliged for advice about the soil. The natural soil of my garden is stiff clay with yellow subsoil, and though I have tried many things, I have failed in getting Strawberries to bear well in it. The aspect of the new bed is nearly due south, in front of a wall; and if you advise it, I am willing to dig out the natural soil to the depth of $1\frac{1}{2}$ or 2 feet, and put in any compost you recommend.—T. J. B.

[As Strawberries generally succeed on a clayey soil we think there must be something radically wrong in your case. Does the soil want draining? If so, do it effectually at once. We confess to being unwilling to recommend extensive wheelbarrow-work in the way of removing and replacing any great quantity of subsoil; but if it be absolutely unfit for vegetation, this may be done with advantage. If the subsoil is a retentive clay, burning a large quantity of it on the spot will be attended with much good, and the mode we have adopted is this: Choose a suitable smooth place for the hearth, then cut two small drains to admit air, crossing each other in the centre, about 4 inches broad and the same in depth. On these lay some bricks, and, in the centre where they meet, a good heap of brickbats or stones. The fire is kindled then and may consist of any description of vegetable rubbish, over which lay lumpy pieces of clay, adding more fuel and clay daily as the fire gains strength. The best material we have found for this fuel are the roots of shrubs or trees, not too large, but as much forked or gnarled as possible. These ugly articles are thus used out of the way, and at the same time turned to good account. For some time it would be better to only throw on lumpy pieces of clay; and do not thrust sticks into the heap, or in any other way disturb it until it has finished burning, which may not be for weeks. This, of course, cannot be waited for in your new Strawberry-bed, which ought to be prepared at once by removing a part of the subsoil and digging a large quantity of sand and some good manure into the remainder. Burning, however, is the best permanent remedy for a stiff clay with only a thin surface soil. Deep cultivation with heavy and repeated dressings of lime will do much to prepare it for many crops, but Strawberries in general dislike lime.]

THE FROST OF JULY 19TH.

THE frost referred to recently in THE JOURNAL OF HORTICULTURE I fear was too general. Here, in Herts, it proved equally severe to any chronicled in these pages, our thermometer, a self-registering one of Negretti, indicating $27\frac{1}{2}^{\circ}$. Yet, though thus showing a temperature of $4\frac{1}{2}^{\circ}$ below freezing, and this within the garden, fortunately few things were hurt, among which we instance those flowers which were expanded upon the Verbenas, whilst the more prominent leaves upon some thousand plants of Geranium Bijou were so injured as to turn brown, and require to be removed. This was done very easily, as they parted from the plants with a slight touch. We are upon a rather elevated site, a river running from west to east of us, and the gardens on its banks showed traces of, for the season, a severe frost. There, in many instances, the Dwarf Kidney Beans and Potatoes were so frozen that their upper portion of growth turned black, and fell over when the sun shone, and Pumpkins in some places were entirely destroyed.

I may add, that my employer informed me a few mornings since, that he had received a communication from his agent in Ross-shire, Scotland, informing him that the frost was so severe there, as to literally cut the Potatoes, &c., to the ground.—WM. EARLEY.

PINUS ARISTATA.

A NEW species of Pine, discovered by Dr. C. C. Parry in the Alpine Regions of Colorado Territory.

During his first botanical expedition to the Pike's Peak region, Dr. Parry, in searching for James' *Pinus flexilis*, found, instead of one, two five-leaved Pines, which evidently had been confounded by Dr. James; thus the discrepancies

of his description are fully explained. His general description of the tree and the edible seeds belong to what we now name *P. flexilis*, while the "erect cones" (smaller than those of *P. rigida*) "with unarmed scales" must be very imperfect young ones of this, or old ones of the new species, which had lost their awns.

On alpine heights, between 9200 and 11,800 or 12,000 feet high, on Pike's Peak and the high mountains of the Snowy Range, Dr. Parry, 1861 and 1862; Messrs. Hall & Harbour (Col. No. 530), 1862. Also, on the highest of the heights of the Coochetopa Pass, nearly S.W. of Pike's Peak (altitude over 10,000 feet), where Capt. Gunnison discovered in 1853 what seems to be this species without fruit; (see Pac. R. R. Rep. II., p. 130;) the leaves which I could compare are those of our plant. Flowers end of June and beginning of July. Flourishing best in the higher elevations and never descending below 9000 feet, in its lower ranges not ripening its fruits as well as on the bleak heights, this truly alpine species—in that respect our representative of the European *P. pumilio*—characterises the highest belt of timber on the peaks of Colorado. On sheltered slopes a tree 40 or 50 feet high and 1 to 2 feet in diameter, it becomes a straggling bush, prostrate, and almost creeping, on the bleak summits of the high ridges. The bark is thin and scaly, even in older trees, not more than 3 or 4 lines thick, of a light greyish-brown colour; that of younger branches smooth, with many large vesicles containing a clear fluid balsam, which remains between the layers of the old bark. Wood white, tough, not very resinous; of extremely slow growth, so that a small, smooth-barked stem of 13 lines diameter exhibited about fifty annual rings, all between 1-6 and 1-60 line wide, the smaller ones consisting of 3 to 6, the widest one of 15 to 25 layers of cells, each cell 0.007 line in diameter. A tree of 2 feet thickness would at that rate indicate an age of over 1000 years; but the annual rings of larger trees growing in favoured situations are wider, and, if a specimen sent by Dr. Parry is not mislabelled, sometimes as wide as one-third line, giving the largest trees a probable age of 500 to 800 years. Branches spreading, very often many of them twisted, stunted or dead; the larger branches and the stem itself frequently covered with young branches or shoots, which seem to keep life in the old trunk. Leaves crowded from the axils of ovate, acuminate, brittle scales, light brown at first, and which, persisting longer than the leaves themselves, cover the branches with their rough blackish remains; leaves light green on both sides without white dots, mostly with numerous exudations of white resin, usually curved upwards, entire on edges and keel, abruptly acutish,

stouter in fruit-bearing, more slender in such trees as produce principally male flowers, in very robust specimens $1\frac{1}{2}$ and rarely even 1 $\frac{1}{2}$, usually about 1 inch long; on sterile branches straight and horizontal, "giving the branches the appearance of so many bottle-brushes." The vagina consist of 7 or 8 oblong scales with fringed margins, adpressed and forming a sheath 3 or 4 lines long on the young leaf, soon spreading and squarrose, falling off in the second or third year. Many lanceolate acuminate scales, perule, sheathe the lower part of the shoots; shorter broader bracts, bearing in their axils the male aments, follow next. The aments together form a very short spike, or rather head, 6 or 8 lines long; often these heads persist on the axis for two or even three years with a few bunches of leaves above each, giving the appearance of a leafy spike 1 or $1\frac{1}{2}$ inch long.

Our figure does not represent this condition distinctly, but shows the numerous naked spaces, about ten in number, which in former years had been occupied by male flowers. We have seen branches with sixteen such naked spaces, proving that leaves were persistent for sixteen years—a fact unheard of among Pines, where leaves are said to endure only three years. The stipitate oval ament 3 to 4 lines long, has a proper involucre of four oblong scales or bracts of equal length. It seems that the involucre of the male ament and the form of the ament of the anthers, together with the fruit and seed, offer characters of importance for the distinction and arrangement of species, hitherto neglected probably because living nature has not been studied as diligently as the dried mummies of the herbaria, and these contain so few good flowering specimens of Pines; the number of leaves, so much relied on, is of secondary consideration, and is often calculated to mislead, separating the most natural affinities, such as our Cembroid Nut-pines with one or five leaves, or the pineoid Pines (*P. Pinea*, *P. Sabiniiana*, *P. Torreyana*), with two or five leaves. *P. sylvestris* has an oval ament 3 lines long, with an involucre of three equal lance-linear acute scales in the axil of a lanceolate recurved bract, which is deciduous with the ament; anther with a short, nearly entire crista. *P. austriaca* has a cylindric curved ament $1\frac{1}{2}$ inch long, with an involucre of about ten very unequal and almost distichous oval scales, in the axil of a linear-lanceolate recurved persistent bract; anther, with a semicircular entire crista, large enough to entirely hide the body of the anther in the yet-closed ament, and give the latter the appearance of a young cone. Crista of the anther scarcely indicated by a knob, smaller than in any Pine examined by us. Female aments single, or two together near the end of the young shoots, bristling with the lanceolate, aristate erect scales, of a purple black colour. Cones oval, obtuse, $2\frac{1}{2}$ to 2 $\frac{1}{2}$ inches long, about half as much in diameter, often covered with resin as if varnished; their purplish-brown or blackish colour is found also in a little group of alpine Pines of the Popocatepetl with three to five leaves, discovered by Roezl. Bracts, as in all Pines, not obliterated ("evanida") as is usually stated, but much altered, and rather indistinct; more or less thickened and partly connate with the base of the scale; in our species, only the upper obtuse mucronate part membranaceous and free; scales 10 to 15 lines long, and 4 to 6 lines wide at their exposed part; transverse ridge of the rhombic rather flat, protuberance of the scale very conspicuous; the slender mucro or awn, from the small rhombic central knob, 2 to 3 lines long, curved upwards, at last tortuous and easily broken off, has suggested the name for the species. Seed nearly 3 lines long, with the obovate wing 6 to 7 lines long; embryo in all the seeds examined by me, with seven short cotyledons.—(*American Gardener's Monthly*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Should the present dry weather continue, the water-barrel will be in continual request among all newly-planted crops. Surface-stirring to be also frequently resorted to for the purpose of preventing a too rapid evaporation. *Broccoli*, where they have been planted between rows of Peas the latter should be removed as soon as they are done with, the ground to be then dug, and the intermediate spaces filled up. *Cabbage*, prick-out the plants intended for spring

use in nursery-beds, that they may get stocky previous to their final planting. Earth-up all the Brassica tribe that are sufficiently advanced, and make succession plantations of Brussels Sprouts, Buda Kale, Broccoli, Coleworts, and Savoys. *Cauliflowers*, the plants now coming into use to be liberally supplied with water to produce close heads. *Chervil*, make a sowing for autumn use. *Eudive*, continue to transplant as circumstances require. Another sowing may also be made. *Potatoes*, the Ash-leaved Kidneys intended for seed may now be taken up and exposed to the sun until they are green. *Turnips*, seize the opportunity of a shower to get in another breadth of Late White.

FLOWER GARDEN.

The season of the year has now arrived at which the flower garden has attained, or nearly attained, the zenith of its beauty, and the amateur or gardener may contemplate with satisfaction the result of his labour in that department; but if there is anything in the present arrangement of colours to mar the effect, it should be noted for correction another season. Much watering will be necessary here during the heat we now experience. Continue to remove dead flowers from Roses, and give plenty of manure water to the autumn-blooming varieties. Plant-out rooted cuttings of Pansies in nursery-beds in a shady situation. Propagate Pansies, keeping them well-watered if the weather is dry until they get established, and save seed of choice sorts. Plant-out Pinks in beds, water freely in dry weather. Water layers of Carnations and Picotees in dry weather. Keep choice Dahlias thin of shoots and buds. Trap earwigs. Water American and other choice shrubs in dry weather. Shrubs that were planted late in spring will require liberal supplies of water and mulching to prevent evaporation. Train climbing plants neatly to trellises. The lawn during the present hot weather will sometimes require to be gone over with the scythe in the middle of the day to cut off any straggling tufts of grass.

FRUIT GARDEN.

Peaches, Nectarines, and Apricots to have frequent attention in keeping them well nailed to the walls, to guard against high winds. The fruit also to be exposed to the action of the sun as much as possible, without divesting them of leaves, to insure fine flavour and good colour. Continue to make fresh plantations of Strawberries; the ground to be deeply trenched—they like a fresh, stiff loam. The wall fruit trees will demand a good supply of water at their roots, to be mulched with short litter.

GREENHOUSE AND CONSERVATORY.

Keep everything in the conservatory in the neatest order, shifting to other quarters those plants that are fading in bloom, and replacing them by others that have been prepared for the purpose. Keep the creepers neatly trained, and occasionally washed with the engine or syringe. New Holland plants and Heaths that have been standing out of doors for some time to receive immediate attention, if wet and windy weather prevail. Some of the best and most tender varieties to be secured by placing them in cold pits or other secure situations. Persevere in keeping all plants subject to the mildew clear of that pest by dredging them with sulphur, as the season is now arrived when hardwooded plants are subject to it. Persevere in clearing-off all decayed blossoms, and pinching back luxuriant shoots. It will be much to the advantage of the inmates of plant-houses to reduce the shading after this time, to enable the plants to ripen their summer's growth, allowing more air to keep down the temperature, and to check any tendency to a second growth which may show itself, and which can only take place at the expense of next season's bloom. Examine the stock of pot plants to see that none are suffering from want of pot-room or other attention necessary to assist them in making young wood for blooming next season. Young, vigorous plants, however, sometimes require to be watered rather sparingly at this period to prevent their making a second growth. Cinerarias for early blooming should now be growing freely, and should be shifted when necessary, for if they are to form large specimens for blooming in winter they must not be permitted to sustain any check. Remove suckers whenever they can be obtained, and pot them for spring flowering. The conservatory-borders will now require most liberal waterings, and care

must be taken to insure a certain supply of water to any plants which have recently been turned out of pots. Passifloras, and, indeed, the greater portion of conservatory climbers, will be growing fast, and will require frequent training. Thin-out weak and overluxuriant shoots, and reserve only sufficient to produce the bloom desired, which will be finer, and the plants themselves more capable of producing well-matured wood when these little attentions are performed regularly.

STOVE.

Such of the inmates here as are intended for the decoration of the conservatory in autumn and early winter should be carefully looked over, shifting those which are likely to want more pot-room, so as to get the pots well filled with roots before the blooming season. Maintain a moist growing atmosphere, and ply the syringe vigorously upon any plant at all infested with red spider. Brugmansias, Clerodendrons, and other large soft-leaved plants should be frequently washed to keep down red spider, and to be well supplied with liquid manure to keep them in a vigorous state of health, which adds so much to their beauty. Various stove climbers, as *Quisqualis*, *Allamandas*, *Combretum*, &c., will bloom for a considerable portion of the summer if the shoots on which the flowers are borne are slightly cut-in when the blooms decay; as anything which prolongs the beauty of these favourites is valuable, the above instructions should be put in practice. As the growing season for Orchids is far advanced, therefore encourage any backward plants with plenty of heat and moisture while this can be safely done. See that plants growing on blocks and on baskets are properly supplied with moisture at the root. Syringe lightly morning and evening, and sprinkle the floors, &c., frequently so as to keep the atmosphere thoroughly moist.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WITH a splendid harvest moon at night there has been glorious weather during the day for bringing to perfection the precious fruits of the earth; but though we had a nice shower on Saturday week, we are still feeling the effects of want of water, yet thankful for the supply the rains gave us. Moved the ground among all advancing crops we could get at to let the air in, and keep the heat out. Cleared away the haulm of Peas that were past being useful in the kitchen; turned part of the ground into Celery-beds, as the plants would spoil if kept longer in their temporary beds. Most of our beds are 4 feet wide, and contain three rows. Watered the earliest-planted, soaking them as well as we could, and earthed-up a piece for early use. On the other plants watered merely threw half an inch of dry soil on the surface, to keep the moisture from evaporating. We never think of acting on the old rule, "Give the Celery a little earthing-up." With the exception of a sprinkling of dry soil after watering, we seldom at this season earth-up until three weeks or so before we want the plants for use, and we do this all at once, having tied the plants previously. We do this for reasons several times given, and based on the natural habits of the plant. Of course, as winter approaches we are obliged to earth-up all Celery, not so much to blanch as to prevent the heads being injured by frost. Prepared part of the ground occupied by Peas, by deep digging and manuring, for winter Spinach, preferring the Flanders or Prickly-seeded, and winter Onions, part to be drawn for salads, and the other part to be transplanted for early spring and summer use. What are still left of such planting have had all the tops laid flat with a rake, which will help the swelling of the bulbs, and arrest mere top-growth. Our main summer crop will not need this attention for a week or two, as they are scarcely large enough yet. Ten days ago they looked as if mildew meant to attack them, but the timely rains settled that matter for us. Took-up Potatoes as we could get at them; and Greens, Brussels Sprouts, &c., having been planted between the rows, watered the plants, and turned the earth over to the stems. Shaded Cauliflowers, Turnips, Lettuces, Radishes, &c., as we dread being out of water, and the sun is as bright as ever. Oh! for a sweet prattling brook! but then there would be something else

we would want. There is less exercise of thought when there are no difficulties to surmount.

Looked after Cucumbers as to stopping, thinning, and watering; shading, too, to save water. Sowed a bed of Dwarf Kidney Beans, to which we can give a little protection. Have had them good in the same place up to the middle and end of November. Sowed also a row of Bishop's Longpod Pea, to which we shall also be able to give a little protection, and if the season is fine we will get some nice late gatherings from them. This hot weather is bringing on succession of Peas before their time. A friend very fond of White and Scarlet Runners, says he is quite in a fix for want of stakes this season, and that he will have no crop. Why and wherefore? We believe as many Beans may be had without stakes as with them; and we have told our friend to nip the point out of his Runners, to cover the ground right up to the plants with short grass or clean litter to keep the pods clean, and there will be a prolonged gathering. We consider the cleanliness of the pods to be essential, as, in our opinion, all such Runners and Kidney Beans are anything but improved in flavour when washed or passed through water before being placed in boiling water. In the strange fancies at the present day, such as introducing Carrots and Beetroot as rows in ribbon-borders, we are very much surprised that no one has tried a row of Scarlet Runners, treated on the nipping system, so as to keep them from 12 to 18 inches high. We know of nothing more striking as a mass of scarlet flowers, and even we might say more appropriate if we could keep at a distance all visions of the kitchen and the stewpan. If we are not the creatures of circumstances, we are in many respects the slaves of associations.

Cleared and watered Mushroom-beds, which in our open sheds are producing Mushrooms as fleshy and nice as they can generally be had in January. There is nothing like simplicity after all if minutiae are looked after. If these little matters are too little to be cared for, the finest materials may prove very unsatisfactory.

FRUIT GARDEN.

Gave copious waterings to Fig trees, which are yet far from being exhausted of fruit. Watered Vines also. Sulphured the pipes in houses, as a little heat is put on on cold nights. Finished gathering out of the early Peach-house, and took the lights off by degrees for painting. The house has lasted two months, the last being that excellent Peach the Walburton Admirable, almost as fine as a Noblesse. Have had a few Nectarines, Peaches, and Plums from orchard-house. The birds thinned our Elton Strawberries before we could net them; but Keens' Seedling, planted out as soon as forced, are already producing some fine berries, with promise of more coming, and netted them, as the thrushes know all about their sweetness. Netted all the Currants we think of saving for tarts and dessert. For the latter purpose we have always noticed that they may merely make a show—no one seems ever to taste them. Netted Gooseberries by placing rails higher than the bushes at the sides and middle of a small quarter, and throwing a net over the whole, securely fastened at the sides. The birds dislike this much more than where a net is merely thrown over the bushes, and there is no difficulty in going inside and taking what you want. Will dig down a piece of Strawberries, and will plant with winter vegetables that had been previously pricked out. Moved all the Strawberries laid in small pots, and began potting them as quickly as possible. We feel obliged to Mr. Gross for his note at page 70. The mode he recommends is a very good one; but we rarely can command the room. We have mentioned the same plan in previous volumes, and also taking the runners from such early-forced plants, pricking them out under glass, and lifting with balls and potting immediately, which is a very good plan if shading and syringing are attended to at once. We have also previously mentioned the plan of taking the runners, as soon as formed, out of doors, pricking them out 4 inches apart, on a slight hotbed, with glass over them, and lifting with balls. In cold northern places we believe that small late runners of this summer, pricked out on a border, to stand the winter, and raised and potted next season, will do the best. For extraordinary crops we have found no plan better than resting the smaller forced plants be-

hind a north wall, shaking them out of their pots in July, and repotting firmly in rich loam, and treating as for younger plants; but in such cases the fruit individually is not generally so fine. In the short article alluded to so kindly by Mr. Gross, the chief subject of discussion was, whether it was better to layer the runner at once in the fruiting-pot, or use a small pot, and to that the remarks were chiefly confined. Our own experience enables us to say that there can be no doubt of Mr. Gross's plan being a good one. From a press of other matters we are a week or two behind in the potting, but there is every prospect of a fine autumn, and a week of such weather soon makes up.

ORNAMENTAL GARDENING.

This, for various reasons, has occupied our chief attention. Arranging conservatory, potting plants, Primulas, Cinerarias, taking cuttings, nipping off every wasted flower from flower-beds, stirring where an inch or two of soil could be seen, clipping and cleaning edgings, rolling walks that were like adamant, so that no mark of the broom should be left at sides where the broom had to be used for clippings, giving a little water as if it were wine, where there were signs of flagging—the *Amplexicaulis Calceolaria* being our most troublesome customer in this respect, tying and fastening where necessary, and rolling the short-slaven lawn that it might be as smooth and easy for the feet as a Turkey carpet. Even the pleasure derived from seeing a fine flower-bed is very much diminished if you must reach it by a walk enough to make a corn scream, or a lawn in hard lumps that the thin slipper of a lady is a poor protection against.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers.

PEAR LEAVES SPOTTED (*Hawck-eye*).—The leaves are infested with the "Slimy Grub"—the larva of the Pear Saw-fly, *Selandria rithopsis*. Syringing with lime water, or dusting the grubs with lime powder, destroys these grubs.—W. W.

GOOSEBERRY CATERPILLARS (*G. E.*).—There are two caterpillars which attack the leaves of the Gooseberry. One is the larva of the *Abraxas grossulariæ*, or Magpie Moth. This is figured in "The Cottage Gardener's Dictionary;" but the caterpillar which is the greatest scourge of the Gooseberry is green, as you describe, and is the larva of a Saw-fly, *Tenthredo grossulariæ*. It has been frequently described in this Journal, but was accidentally omitted in the "Dictionary."

FUCHSIAS AND PELARGONIUMS FOR A WINDOW (*W. Easton*).—Of dark Fuchsias have *Diadem*, *Globose*, and *Voltigeur*; of light ones, *Duchess of Lancaster*, *Pearl of England*, and *Prince Arthur*; of Pelargoniums, *Citrinodorum*, *Floribunda*, *Gaines' Scarlet*, *Prince of Orange*, *Rollison's Purple*, and *Sidon*.

VINERY FOR SIX VINES (*An Old Subscriber*).—With the exception of having good heat, we know nothing of your vinery or what you wish to do with it. At something like random, then, we would say, Plant one Dutch Sweetwater, one Black Hamburg, one Lady Downes, one West's St. Peter's, one Muscat of Alexandria, one *Bowood* Muscat. Any of our large nurserymen will get the Trebbiano for you if they have it not in stock. You may march the Stockwood Vine now. To graft, you had better wait until the Vine has rested, and put the graft on a fortnight before you start the Vine into growth. Or you may start the Vine early, and when in full leaf cut back and graft with a retarded scion. We would try the first. A white Grape, as a Muscat, *Raisin de Calabre*, would be best.

ERRATUM.—At page 65 there is no error in printing, but the period is placed wrong in one instance. "All fine flourishes of penmanship should, therefore, be generally avoided." "Unless" should be the first word of the next period ending in "sentence," which alters the sense as to the use of capital letters considerably.—R. F.

WIREWORMS INJURING VINE ROOTS (*T. C.*).—We would try watering with soot and weak ammoniacal gas water. The surest remedy is to stick slices of Carrots, Turnips, and Potatoes all over the border 6 inches below its surface, examining them every morning and taking out from them the wireworm. A little perseverance will rid you of the enemy. If you had examined the compost well by turning it and mixing some soot and lime with it, you would most likely have escaped the pest altogether.

VINES IN A GREENHOUSE (*L. A.*).—A similar inquiry was answered the other day. Your house, 12 feet long, is large enough for two Vines, but we would recommend one Black Hamburg and one Royal Muscadine. If you plant inside, and the roots are to go outside through the front wall, be sure your inside border is higher than the outside one. We do not know the position of the house; but in general the easiest plan, when the roots are to be outside chiefly, is to make a hole in the wall for the stem and cover what is exposed outside with a box. If you want to keep plants in winter, and the thermometer is never above from 40° to 45°, the Vines will not break until the end of March or the beginning of April, so that you will have no shade of consequence to interfere with the plants from the end of October until midsummer.

FENTILLIC CASTLE GARDEN (*New Forest*).—The smaller walks are gravel and the scroll-beds are filled with beading plants. We cannot give an opinion as to "the smallest scale" to which it is adapted.

PLANTING RASPBERRY CANES (*Joseph C.*).—It is a good plan to be satisfied with "pretty well," rather than follow such an adviser's instructions, who knows nothing about Raspberries, or he would not advise you to attempt an impossibility—namely, to "cause the canes to fruit *two* seasons." Planting three canes together is a good plan; it saves stakes. Training to an espalier rail is better, and staking them is an old plan not yet beaten. Raspberries require rich soil, to be planted in rows 4 feet apart and 3 feet from plant to plant. Allow three to five canes to rise from a stool and pull up all the others, thus throwing all the sap into the future fruit-caness. As soon as the fruit is all gathered cut away the old canes, and that will admit the sun and air, which will ripen the young canes perfectly and give you abundance of fruit the year following. A dressing of manure, pointed-in in autumn, is necessary; and the canes, if strong, to be shortened to 5 feet, or, if weak, to 3 or 4 feet, according to their strength.

MOVING A LARGE HOLLY (*W. R. J.*).—Some gardeners prefer moving the *Holly* in spring, during showery weather, not later than May 1st. The latter part of September, and through October, is a good time to plant or move somewhat large Hollies; but more depends on taking them up with a nice ball than on any particular season of transplanting, and being well supplied with water in dry weather until the tree gets firm hold of the soil.

CONSTRUCTING A FERNERY (*Idem*).—Autumn is the best time to make a new fernery, for the rockwork and soil become settled before the plants are planted in March. March is the best time to reconstruct a fernery; but any time will do, providing every care be taken not to disturb any plants in growth, nor expose the roots of those at rest to sun and dry winds.

THINNING MELONS (*A Constant Reader*).—About eighteen Melons will be a fair crop for your four plants. We have taken as many as twenty and twenty-four. We would advise watering the bed moderately, giving air even at night, and letting the Melons become as big as pigeon's eggs before you thin them. You can then select the best formed and the most regularly placed fruit. When so small they take little comparatively from the plant, and will not require it.

LONICERA AUREO-RETICULATA (*A. B. C.*).—You do not state where you reside; but, unless very far north, your plant against a south wall will not need protection.

BOOK ON LANDSCAPE-GARDENING (*B.*).—London's edition of Repton's "Landscape Gardening and Landscape Architecture."

STRIKING GERANIUMS IN THE OPEN GROUND (*Blandyanum*).—The kinds you mention—Christine, Flower of the Day, Mangles' Variegated, and Cloth of Gold—may be all struck in the open ground in August and the early part of September; but we have generally found it advantageous to allow slow-growing varieties of the Golden section to grow the whole season, and take them up in autumn, keeping them rather warm in winter and taking off cuttings in the spring. Cuttings of all the kinds may, however, be put in now, the only question being, Can they be spared from the slow-growing kinds? Cuttings of Mangles' Variegated ought to be put in early, as they are more difficult to keep than most others; but none do better than Christine.

PROPAGATING HOLLYHOCKS BY CUTTINGS (*Idem*).—As it is late for this work, you must select the young shoots that are not more than half grown, and cut them into lengths of two joints and insert them in a pot or pan, which plunge in a slight heat for a short time. June is a better time than August; but they may yet be propagated in the way we have described. About one-half of the leaf may be left on the upper joint, and about 1 inch of the leafstalk on the lower one.

LILIAM LANCIFOLIUM TREATMENT (*J. S.*).—The young roots recently formed, and which have had one year's growth, may be treated exactly as the old one—namely, be ripened gradually, kept moderately dry till planting time, and then potted as before; but if there were a *Rhododendron* bed on good peat, neither too dry nor too moist, we would plant them in it and let them remain until the bulbs are large enough for flowering. In many situations they flower better out of doors than they do in pots, and their appearance is certainly not less beautiful.

LAYERING LONICERA FLAYA (*Blandyanum*).—Although we have had no experience in layering this plant, yet we believe the same rules will hold good with it as with many others, the growing season being the best for the operation, and laying the young shoots into a sandy soil. In a day or two the tips will turn upwards, when the layer may be half cut through and secured by a hook so as to remain firm in the soil. They will speedily become plants.

WATERING (*A Subscriber*).—In two Numbers, June 16th and 23rd, under the title "Using the watering-pot," this subject was very fully considered.

NAMES OF PLANTS.—(*M. B.*)—We do not recognise the plant said to have "slate-coloured flowers," the set-up is too small to show much character. The so-called Virgin's Rod appears to be a *Phlox*, probably *P. divaricata* or some near ally. It is a native of Virginia, and may be called *Virginia Rod*; but the specimen is a very bad one, and has only the remains of flowers. Send a better specimen in flower. (*J. D. N. P.*)—Yours is *Strophanthus*

dichotomus. (A. Z.).—The smaller of the two plants sent is the Pennyroyal. *Mentha pulegium*. The larger plant is the common Calaminth, *Calamintha officinalis* of Bahington. (C. H.).—1, *Athyrium Filix-foemina*; 2, *Polygonum vulgare*; 3, *Oxannda regalis*; 4, one of the double forms of the common Feverfew, *Pyrethrum Parthenium plenum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CHICKENS LAYING—LAMENESS.

WE do not know that we can answer many of our correspondents better than by entering at some length into the subjects to which their letters refer. Thus "K. O. T." says, "Will you inform me, what is the age at which pullets generally lay? I have now kept chickens and Ducks for nearly twelve years, and I have never remarked a pullet lay at so early an age as this year. I had a brood the first week in February from a pullet hatched some time in March last year. She brought out nine chickens out of eleven eggs, five of which I sold when not ten weeks old for 12s., and kept two, one of which has laid an egg to-day, July 25th. The mother has sat a second time, and brought out eleven chickens from thirteen eggs, and has begun to lay again, having been taken from her second brood about a week ago. This, remember, was a last-year's chicken of the Pheasant-Dorking breed.—K. O. T."

It is almost impossible to state any particular time. It is a question of breed, weather, and management. Food also has to do with it.

It is not the part of any particular breed to lay in winter, nor is it their nature. Pullets arrive at maturity when they attain a certain age, whether that be in May or December; and when they arrive at maturity they lay. No rule can be laid down; we saw an egg laid by a Spanish pullet at Worcester, the youngest-looking bird we ever saw. We have always found Cochins and Brahmas the earliest layers; chickens of these breeds that have been well done, that have had no check, and that are in good health, should lay at from eighteen to twenty weeks old, provided the expiration of this term falls in April, May, or any month before October. If birds are wanted to lay in the winter, those that attain the proper age at the time when the eggs will be wanted should be chosen.

We believe the supply may be made a certainty simply by arranging chickens in such wise that each month shall have its layers. Thus, for November supply, the Brahmas or Cochins should be hatched in May; Dorkings in March, or Spanish in February. It is, however, a mistake to suppose that the fact of keeping a number of May chickens will insure eggs throughout the winter. They will begin in November, but it is more than probable, especially if the weather is severe, that they will not continue to lay more than six weeks, or, it may be, a month. Assuming, then, that they cease laying in the beginning of December, a relay of pullets one month younger than those giving up should be ready. Attention to this will make a supply of eggs a certainty throughout the winter months. Extreme severity of weather must be encountered, and overcome by generous feeding, and all help must be in this way. The only care required in their roosting-houses, even in unusual cold, is security from draughts.

It must be borne in mind hens do not lay in the winter. After laying the first eggs and having been broody, the pullet is a hen, and from that time she lays in the regular season, which begins about March. It will thus be seen, first, that all eggs laid in the winter must be the produce of pullets; next, that to have a succession, the ages of the birds must be arranged accordingly. We do not mean to say hens cannot be made to lay in the winter. A few eggs may be produced by meat-feeding and by stimulating diet; but the penalty is paid, and the eggs are dearly purchased by the destruction of the hen. Disease begins from the moment forced laying is produced, and the price must be paid because the process can only be used successfully with a young hen. The food is thrown away on an old one.

Our observations are principally prompted by the oft-repeated remark that, had people known in time, they would have had eggs all the winter. Few of the May chickens are killed, and therefore, in the language of Friar Bacon's head, "Time is;" and if our readers wish for eggs at the breakfast table in the winter, we believe they can

have them by following our instructions. They are based on the experience of many years, and have never failed.

"CONSTANT READER" says he has chickens two and three months old lame in the legs. He wishes to know the remedy, if there is one.

No fowls are naturally lame when chickens—they may be lame in the legs from weakness. This will be remedied by good diet. They may be lame from very rough stones on the floor of their houses. This can be remedied by raking them off. The most serious remains behind: they may be lame from chill or damp from floors of wood, brick, or stone. The cure is removal and the substitution of gravel or earth, the former preferable. Where objectionable flooring is used, its effect generally shows itself in enlarged knees; and the pain or discomfort arising from them causes the bird to sit down and rest on the leg from the knee to the foot, all that part being on the ground—not with the body poised as it is when at roost, but resting a dead weight upon it, and rising with evident difficulty.

MERTHYR TYDFYL SHOW.

THE seventh annual Meeting of the Merthyr Tydfyl Poultry Exhibition took place on the 30th ultimo, being held in the Market Hall, in conjunction with a show of fruits and flowers. R. T. Crawshay, Esq., of Cyfarlifa Castle, also offered a large number of prizes for the best-grown vegetables by cottagers, each district in this widely spread neighbourhood having its special prizes, and, consequently, producing an amount of close competition that few of our readers could possibly credit who did not witness it. It is, though somewhat a digression from the poultry department, a pleasing feature to record, that the vegetables thus entered for competition, and grown under many local disadvantages exclusively by working men, were quite equal to those exhibited in the classes expressly appointed for amateurs, and such as would tend much to the credit of any similar meeting even in the most favourable districts.

The Market Hall at Merthyr affords every necessary advantage for the successful holding of a poultry show, being alike spacious, airy, and well lighted. On the present occasion it presented the gayest appearance possible—flags, pennants, and banners meeting the eye in profusion on every side, and many waggon-loads of evergreens were used as decorations. The services of a brass band made the arrangements complete, and, as the weather was every way favourable, success ensued.

Although entries were admissible from any part of the kingdom, most of them came from breeders not far removed from Merthyr; this fact caused the entries to be somewhat limited, still, as a whole, the Show could not be pronounced otherwise than a good one. *Dorkings* came first. This neighbourhood seems rather scanty of Dorking-breeders, only three pens being entered. They were, however, good. This time of year being just about moulting season, the *Spanish* showed to disadvantage, consequently need no particular mention. In the *Game* fowls several very good pens were present. It should be remembered, however, by exhibitors that adult *Game* fowls should always be shown "dubbed," or their chances of success are seriously diminished. To *Game* whilst chickens this rule does not apply. Of *Cochins*, the Partridge-coloured ones were decidedly superior to any of the others, besides being shown in excellent feather. In the *Hamburgs* the Merthyr amateurs seem to have paid but little regard to combs, imperfections in this respect being always a fatal objection, though in these classes abounding. The *Black Hamburgs* on the contrary were truly good. The classes for *Malays*, *Polands*, and *Selbright Bantams* were without a single entry. Some very good *Red Fife Game* Bantams were shown; also capital *Silkie*s, both *White* and *Brown* ones. The entries in the *Single Cock* classes were very limited.

The *Geese* and *Ducks* were very creditable; and in the *Variety* class a splendid *Shell Drake*, "same as a Robin," drew many admirers to its pen.

The poultry prizes offered exclusively to working men were closely contested; a truly useful "cross" between the *Malay* and *Cochin* was here well shown, possessing extraordinary advantages as a table bird, combined with a constitution remarkably hardy during chickenhood.

It appears that for the last season or so the Merthyr Tidfyl Show was discontinued. Under its present management, it now appears certain to prove permanent and most successful—an issue it well deserves, neither labour nor expense being spared in its resuscitation.

DORRINGS.—Second, Rev. E. Nicholl, Llandough Rectory, Cowbridge. Third, J. Buckley, Penyfai House, Llanelly. Commended, R. T. Crawshaw, Cyfarthfa Castle.

COCHINS.—First, J. Carr, Hafod, Swansea. Second, G. Paddon, Swansea. **HAMBURGS** (Gold and Silver-spangled).—Prize, — Wrenn.

HAMBURGS (Gold and Silver-pencilled).—First, E. Payne, Cardiff. Second, J. T. Williams, Penrheol.

DORRINGS.—Prize, R. T. Crawshaw, Cyfarthfa Castle. **SPANISH.**—Prize, R. T. Crawshaw, Cyfarthfa Castle.

GAME.—First, R. T. Crawshaw, Cyfarthfa Castle. Second, Withheld. **GALLINÆ** (Cock and two Hens).—Prize, R. T. Crawshaw, Cyfarthfa Castle.

GANDER AND TWO GESE.—Prize, R. T. Crawshaw, Cyfarthfa Castle.

DRAKE AND TWO DUCKS (Aylesbury).—First, R. H. Nicholas, Malpas, near Newport. Second, D. Williams, Penrheol.

DRAKE AND TWO DUCKS (Black).—First, Withheld. Second, R. T. Crawshaw, Cyfarthfa Castle.

DRAKE AND TWO DUCKS (Muscovy).—Prize, R. T. Crawshaw, Cyfarthfa Castle.

TURKEY COCK AND TWO HENS.—First, R. T. Crawshaw, Cyfarthfa Castle. Second, J. Buckley, Penyfai House, Llanelly.

PRIZES FOR WORKING MEN ONLY.

COCK AND TWO HENS (Any breed).—First, W. Keddart, Penydarren. Second, R. Rees, Brecon Road.

DRAKE AND TWO DUCKS.—Prize, W. Cuff, St. Fagans. Highly Commended (Shell Duck), owner not known.

DUCKINGS.—First, W. Cuff, St. Fagans. Second, W. Seal, Gwalced-y-Garth.

CHICKENS.—First, W. Nicholas, Caerphilly. Second, W. Keddart, Penydarren.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, officiated as Judge.

NEWMILLERDAM POULTRY SHOW.

ON Tuesday the eleventh annual Exhibition at the above place was held in a field adjoining Chevet Park, and we think it proved a successful one so far as numbers attending and financial matters were concerned. The show of poultry was tolerably numerous, and some very fine birds were exhibited, each variety of breed having some manifestly superior bird included in the number. Among the more notable fowls shown were the *Game* of Messrs. Brierley, Hellewell, and Vickerman; they were splendid birds and shown in good condition. The *Cochins* of Messrs. Dawson and Newton were so good that the Judge had some difficulty in awarding the first prizes. There were other good birds in these classes. *Dorkings* were very good. The chickens were the best we have met with this season. There were only five pens of *Spanish*, and not so good. Golden-spangled were very nice. The chickens shown by Mr. Ellis, of Leeds, were first-rate, and a large figure was offered for them, but they did not change hands. There was a poor entry of Silver-spangles, but the prize birds were good. The Variety class was well filled, and the first prize went to a pen of Golden-pencilled, second to Silvers—both very good pens, beating Mr. Dawson's Sultans, Brahmas, Black Hamburgs. There was a very large show of *Bantams*; there were two classes open for them.

Ducks and *Geese* were not so well shown as we have seen at this Show; and the *Turkeys* were very poor.

This part of the Exhibition was under the supervision of Mr. John Crosland, jun., who gave all his attention to the fowls, and his arrangements were very good.

GAME (Black-breasted and other Reds).—First, Mr. Brierley, Rochdale. Second, Mr. Hellewell, Sheffield.

GAME (Any other variety).—First, Mr. Hellewell, Sheffield. Second, Mr.

Charlton, Bradford. *Chickens.*—First and Second, Mr. Vickerman, Chick-enley.

COCHIN (Cinnamon and Buffs).—First, Mr. Dawson, Mirfield. Second, Messrs. H. & G. Newton, Leeds.

ANY OTHER VARIETY.—First, Mr. Dawson, Mirfield. Second, Mr. Brierley, Rochdale.

COCHIN (*Chickens*).—First, Mr. Dawson, Mirfield. Second, Messrs. H. & G. Newton, Leeds.

DORRING.—First, Mr. Pickard, Wakefield. Second, Mr. Himsforth, Lupset Hall. *Chickens.*—First and Second, Mr. Pickard.

SPANISH.—First, Mr. Vickerman, Chickenley. Second, Mr. Cooper, Bournley.

PHEASANTS (Golden).—First, Mr. Himsforth, Lupset Hall. Second, Mr. Ellis, Leeds. *Chickens.*—First, Mr. Ellis. Second, Mr. Himsforth.

PHEASANTS (Silver).—First, Mr. Vickerman, Chickenley. Second, Mr. Hellewell, Sheffield. *Chickens.*—First, Mr. Vickerman. Second, Mr. Hellewell.

ANY DISTINCT BREED NOT NAMED.—First, Mr. Brierley, Rochdale. Second, Mr. Vickerman, Chickenley.

BANTAMS (Black or White).—First, Mr. Charlton, Bradford. Second, Mr. Harrison, Wakefield.

BANTAMS (Any other variety).—First, Mr. Hellewell, Sheffield. Second, Mr. Brierley, Rochdale.

TURKEYS.—First, Mr. Waterton, Walton Hall. Second, Mr. Fawcett, Wakefield.

GESE.—First, Mr. Fawcett, Wakefield. Second, Mr. Totty.

DUCKS (Aylesbury).—First, Mr. Fawcett, Wakefield. Second, Mr. Johnson.

DUCKS (Rouen).—First, Mr. Bentley. Second, Mr. Athey.

APIARIAN NOTES.

THE change of weather about the 21st of June brought some fine sunny days, and after the first week in July there was a considerable honeydew for some time, which proved most favourable to the bees, so as to make up in some degree for the loss sustained by nearly three weeks' rain in June, generally the best honey-gathering month in England.

It was vexatious to read of the losses and failures of that enterprising apiarian, "A DEVONSHIRE BEE-KEEPER;" but the question is, Has he not been too experimental? He was unlucky in having three successive bad summers as those of 1860-61-62, and I certainly must condole with him, after so much pains taken practically and scientifically. That such a train of disasters should follow his apparently well-directed plans and operations seems strange; his motto should be "Nil desperandum," and go on.

CORSAIR BEES.—For some weeks my hives have been infested thus early in the season (the 24th of July), and these plunderers have attacked a weak swarm in a box or wooden Nutt's hive. I have been forced to shut these weak bees in for some hours early in the morning, and by these means have destroyed a good many of the marauders as they arrived. Bees generally are most troublesome in this their great failing in spring and autumn.

BREEDING.—This is still going on amongst my bees, as numbers of bees are constantly going to the water-troughs. It seems likely, should the weather prove fine for a couple of months, that the late districts and heath countries will certainly have the advantage. A swarm of a near neighbour's, hived on the 1st of July, has increased in weight nearly 20 lbs. This I attribute to a week's honeydew which came between the 3rd and 16th of July.

DRIVING BEES.—Mr. Woodbury seems to excel in the manipulation of bees; but I agree with "A. W." in No. 121, that driving bees very often fails, and unless the greatest patience and forbearance are used never succeeds. "A. W." also agrees with me about natural swarming; I have no doubt that the spirits of bees and their unusual activity are diminished by the constant practice of encouraging artificial swarming. I call it fighting against Nature. Nevertheless I must own, as an old-fashioned bee-keeper, that the order of the day is all for experimental operations and new discoveries, many of these latter still problematical.

THE WEATHER.—This month of July, as far as it has gone (to the 25th), has been a most extraordinary month. I have seen frost in many years for a great part of the month of May, and snow once or twice in the first week in June; but I have never seen such a variation in the temperature in July in the west of England as in the present month. We have had five or six white frosts; on the 18th the thermometer, before sunrise, stood at 32°. Previous to this, from the 9th to the 16th, the thermometer varied from 50° to 81°, with honeydew for seven or eight days. In exposed situations the kidney beans and other tender annuals were quite discoloured by the frost.—H. W. NEWMAN, *Hillside, Cheltenham*.

CHLOROFORM FOR BEES—THE SEASON IN LINCOLNSHIRE.

"A CONSTANT SUBSCRIBER" is referred by you to "Payne's Bee-keeping" for directions to use chloroform for stupifying bees. Perhaps you will permit me, as one who has several times acted upon those directions, to state what has been, with me, the invariable result—that of total subsequent desertion of the hives. The quality of the honey is certainly not affected by it; but if preservation of the bees is also a consideration, it is a total failure; as, after trying it six or seven times some years ago, I always found them desert within from ten to fourteen days, and also carry with them every particle of honey the operator had spared. I would recommend your correspondent to endeavour to acquire confidence in the manipulation of his bees—and confidence is all that is required for any operation—and he will then find that no stupifying agent at all is necessary. I find it practicable to get on without that universal resource of apiarists—the tobacco-pipe, which constitutional infirmity forbids me to use.

It is pleasing to find that in most parts of the kingdom the season has this year been so good. I can state that in Lincolnshire it is some time since it has been so good; and in spite of "foul brood," that has been such a plague to our Devonshire friend, having been introduced into my apiary, I have been able to confine it to the loss of three hives. The general result in swarms and honey is most satisfactory.—G. F. B., *Spalding*.

BEE-KEEPING IN DEVON.—No. XX.

CONVALESCENT.

As I am relating my own experience for the benefit of others, and am therefore desirous that they should take warning by my failures and follow me only in my successes, I may at once say that the disease has reappeared in the colony whose original queen was stated in my last to have been sent to St. Austell; and I would record at the same time my conviction, founded on experience, that whenever foul brood attacks a stock, partial excision or removal of infected combs is of no avail: nothing less than entire deprivation and transferring into a perfectly pure hive is likely to effect a cure.

In the case also of one of the last two operations described in page 79, I had the mortification a few days after my article was written of finding that the disease had broken out in the new combs, and I have therefore been compelled to resort to an operation of a different, and, I trust, of a more effectual character. The other colony treated in a precisely similar manner, remains, however, perfectly healthy, and was the strongest in my apiary. I say was the strongest, for I have this day (July 30th), despatched it to Kenfrewshire, where, in the hands of the bee-keeper of that ilk, I trust it may flourish to his heart's content, and that we shall learn in due course that it has fully indemnified him for a certain amount of "hope deferred" which he has suffered in the matter of Ligurians owing to the unfortunate state of my apiary. One point it will undoubtedly enable him to decide before long, and that is the longevity of worker bees at this season. On the 4th of this month all the combs were exchanged for those of a black stock containing, therefore, black brood, and as the queen regnant is a perfectly pure Italian, the period of the complete disappearance of the ordinary English species will, of course, mark the exact duration of the summer life of the working bee.

Thus far I had acted to some extent on the opinions of English authors, none of whom appear to have been perfectly cognisant of the extremely infectious character of foul brood. Nor could I myself at first realise the virulence of the contagion, being disposed to imagine that the removal of the polluted brood-combs would alone be quite sufficient to work a radical cure. In this idea I was confirmed by one of the ablest of the apiarist correspondents of *THE JOURNAL OF HORTICULTURE*, who, in a letter with which he kindly favoured me on the subject, attributed the whole of the mischief to my experimental operations allowing the brood in the first instance to get chilled, and, therefore, requiring only the excision of the affected parts to work a complete

cure. Experience has, however, proved the erroneousness of these opinions. Few hives of any kind escape the loss of some of their brood every spring from sudden changes of temperature, and the embryos being removed by the bees no farther mischief ensues. In my own case I have often in former years accidentally reduced the population of hives to so low an ebb that more or less of their brood has perished; but this has always been the extent of the injury sustained. As it has been said, that when bees are left to themselves and are allowed to follow unrestrained the impulses and instincts of their nature no such disorders arise, I may be permitted to state that foul brood was unquestionably introduced into my apiary by infected combs from common cottage-hives in which the bees had been managed in the ordinary way.

My next experiment was the mode of cure indicated by Dzierzon, who nevertheless advises, as the best course, to destroy immediately by means of sulphur every stock in which foul brood is found to exist. Having deprived the bees of all their combs and placed them in a clean hive, I confined them (first insuring perfect ventilation by removing the crown-board and substituting perforated zinc), without food for twenty-four hours, in order to be certain of their consuming whatever of the infected honey they might have taken from their original domicile. To my astonishment a full third of their number perished during their imprisonment from some cause which I found myself unable to discover, but which appeared not to be accidental, as a similar loss occurred in both of the only two cases in which confinement was resorted to, and caused me on that account to abandon it. Having been allowed to work three days in their new habitation, they were once more unceremoniously ejected, and placed in a hive with a few clean combs, in which they were suffered to remain; all the beautiful combs which they had made during their sojourn in the intermediate habitation being at once consigned to the melting-pot. This plan appeared to work an effectual cure; but as I have departed from it in the matter of imprisonment, I will give full particulars of my more recent mode of operating, which thus far promises the best results.

First, however, let me indorse the opinions both of Dzierzon and Rothe, that except under very special circumstances it is unadvisable to attempt the cure of a foul-breeding stock; better, far better, to consign its inhabitants to the brimstone-pit, the hive itself, if a straw one, to the flames, the comb to the melting-pot, and appropriate the honey to any purpose except that of feeding bees.

Before starting it was requisite to insure the transfer of the bees to unpolluted hives, and here I found that Dzierzon declares that every hive that has contained a foul-breeding colony should be exposed to the sun and air for two years before being re-stocked. In my own case this was simply impossible, and I therefore adopted the practice of another German writer on the subject—viz., to scrape out the hive very carefully, wash it all over with a saturated solution of chloride of lime, keeping it closely shut up for twenty-four hours, and then, after thoroughly washing it in clean water, exposing it to the sun and air until the smell of the disinfectant had passed off. This method has the advantage of enabling one to use a wooden hive again after the lapse of a couple of days, and is, I believe, thoroughly effectual.

Having in this manner obtained a supply of pure hives, my first step in each case is to capture the queen and secure her in a cage. This is very important, as insuring the safety of the royal person during subsequent operations as well as stopping breeding, and effectually preventing the bees from deserting the unfurnished domicile to which they are temporarily consigned. One of my colonies did, in fact, attempt to do this, but knowing that I held so important a hostage I was enabled to view their proceedings with perfect equanimity, feeling myself to be the real master of the situation, and was not a little amused to see the truants after filling the air for a long time with all the noise and bustle incident to swarming, at last sink crest-fallen back to the unfurnished mansion in which their sovereign was held a prisoner, and, confessing themselves beaten, commence comb-building therein, a thing which they had hitherto resolutely abstained from doing. The queen being, therefore, confined and placed in a clean and empty hive, all her bees are brushed from their combs into it as rapidly as possible in order to prevent

their carrying much of their infected honey with them, whilst the combs themselves are set draining out of the bees' reach and consigned as quickly as possible to the melting-pot. After the lapse of three or four days the queen (still imprisoned), and bees are again transferred to another clean hive furnished, if possible, with a few pure combs, and in this they are suffered to remain, their queen being released in the course of a day or two, or as soon as they appear contentedly settled. Let me again repeat, that all these operations, in which tainted combs must perforce be exposed to the attacks of robbers, should be performed as rapidly as possible, and either at a distance from other bees, or at least late in the evening.

Having now, as I hope, by these means restored my remaining colonies if not to a thoroughly healthy, at least to a convalescent condition, I may be permitted to take a retrospective glance at the amount of mischief which this pestilential disease has wrought in my apiary during the past season. I commenced the bee year with either sixteen or seventeen stocks, to which must be added five received from various friends for the purpose of being Ligurianised. During the spring I sent out four Italian stocks with varying ill-fortune. All the others are now merged, by divers unions (with the particulars of which I have not deemed it necessary to encumber my narrative), necessitated from time to time by their dwindling condition, into eight* stocks with pure Ligurian queens, nearly all of them reduced to the condition of recent swarms, and two queen-rearing colonies, the entire black and hybrid elements having been eliminated from my apiary. It will thus be seen that by this visitation I have sustained an actual loss of about a dozen stocks, since I am, of course, accountable to my friends for those with which they have intrusted me, besides losing the entire honey harvest, and the whole of the natural or artificial increase which would have resulted under ordinary circumstances.

Still, if the narrative of my misfortunes should be the means of directing attention to a disease not, I fear, so very uncommon among our little favourites, although almost entirely overlooked by English authors, and if, at the same time, it throw some light on the otherwise unaccountable failures related by Mr. Fairbrother and "BAR-HIVE," I shall not remain altogether inconsolable under the losses which have befallen me in my capacity of—A DEVONSHIRE BEE-KEEPER.

WEAK AND UNHEALTHY HIVES.

I HAVE perused with feelings of sympathy—mingled, let me say, also with surprise—the lamentable plaint which appeared in your Journal from its esteemed correspondent "A DEVONSHIRE BEE-KEEPER," regarding the weak and unhealthy condition of his apiary this season—sympathy on account of the worries and disappointments incident to such a state of matters; surprise, that one displaying hitherto such a heroic and undaunted spirit under the many difficulties and perplexities with which he has often been surrounded, and whose fluent pen has been ever ready to answer all the inquiries, and to solve all the doubts of the numerous parties who appealed to him for advice and information, should write in such a desponding strain. This appears to me even a greater mystery than the one which has apparently for the present overwhelmed the spirit and prostrated the energies of our friend.

You will permit me, therefore, to trespass a little on your space while I consider a few of the causes which lead to the state of matters here complained of—weakness and unhealthiness in hives, and see whether the so-called mystery may not receive an easy solution, and the evils in question be satisfactorily accounted for.

I have chosen the words "weak" and "unhealthy," which are terms pretty well understood among apiarians as denoting a state or condition the reverse of prosperous, premising only that the latter word "unhealthy," does not necessarily imply the presence of the disease, properly so-called, among the bees; but is only meant to indicate the existence of some evil or defect in the hive which, as I have already said, is adverse to prosperity.

* I should now say seven stocks, one having been despatched to Renfrewshire.

In the cases before us (for Mr. Woodbury refers to Mr. E. Fairbrother's case as one similar to his own), it is, of course, not easy in the absence of full particulars, and of a personal knowledge of all the circumstances, to speak decisively as to the cause of the deterioration and decadence of the hives in question; but judging from the facts communicated, it does not appear to me that either of the cases mentioned is beyond the reach of a true solution. I may here premise, however, that Mr. E. Fairbrother's case and Mr. Woodbury's seem to me entirely dissimilar in their origin and character. Mr. Fairbrother no doubt complained of his bees deserting and his hives gradually degenerating and dwindling away without any apparent reason; but it does not follow that because the results were somewhat similar the evils themselves were the same, or that these results were brought about by the same causes. When I read Mr. E. Fairbrother's communication I was not the least surprised at it. I did not consider it a wonderful thing that hives in certain circumstances and in certain localities should not sometimes prosper. Pray let me ask, What are the elements of prosperity? Mr. Fairbrother himself in a subsequent communication answered this question, and therefore his own case, completely when he said—First, fertility in the queen; second, good pasturage within reach; third, favourable weather. The further question then arises, Were any of these elements wanting in his case so as to account for failure? In the absence of a knowledge of circumstances I cannot of course pronounce decidedly as to the real cause or causes; but if there existed no radical defects in the hives themselves, no lurking evils within—if the hives when put down in his apiary were strong, vigorous, and healthy, and if a gradual dwindling away took place—and if on repeated trials with different stocks under like circumstances the same results ensued, then I should have no doubt in ascribing the cause of failure to locality alone. Let me tell Mr. Fairbrother, and all whom it may concern, that there are certain localities in which bees do not and cannot thrive. Woolwich may be one of these: I should fancy it is. But independently of the smoke and other nuisances incident to a town like Woolwich, bees do not like a town life. They lose themselves and are trampled upon by hundreds amid the streets and lanes of a large town. They have to travel far for food; and even when the apiary is situated in the outskirts, the bees have only access to the fields on one side of them. Within the radius of a mile they can only resort to a mere segment of a circle for supplies, while the remainder may be to them worse than barren. True, all towns are not alike, but as a general rule I should pronounce a large town locality for an apiary to be most ineligible in every sense. Should the amateur cultivator prosecute his studies in such localities, he must do so under great disadvantages and be prepared for considerable sacrifices while enjoying his pleasures. It is of little consequence for Mr. Fairbrother to inquire "How far will bees fly for food?" The real question is, "How far can bees profitably and with advantage afford to fly for food?" The nearer and more abundant the pasturage, the better will they prosper; the more distant and scarce, the reverse.

I know well experimentally what it is to combat with the disadvantages and evils of a town locality. With every fostering care and attention, the population of any of my hives is never nearly equal to such as are situated in the open country, nor do they ever approach their prosperity. If I were to choose a site for an apiary it would neither be in towns nor in the neighbourhood of towns, but in some spot far removed from the busy haunts of busy men.

Mr. Woodbury's case assumes to my mind a different aspect altogether. He has tested his locality with different results, and therefore, the same objections cannot apply here. The evils of which he complains I attribute to his own creating—they have in my opinion been brought about solely by himself. And here let me state the broad truth at once, which I challenge all to gainsay—namely, an experimental apiary can never be a thoroughly prosperous one. Let me impress this truth upon the minds of all the apiarian readers of this Journal.

I have operated more than most apiarians in my day, and know full well the general results and effects produced by the various operations in which I have engaged; and I will make this remark as generally applicable to all these, that

unless performed in strict accordance with the natural instincts and habits of the bees and a due regard to time, circumstances, and condition, the results will always be unsatisfactory and frequently productive of much evil.

It was reported lately in this Journal, that at a meeting of German bee-keepers the question put into the hands of the celebrated Dzierzon to support, was the following:—"Why are artificial swarms to be preferred to natural swarms?" To the credit of that great apiarian he had the boldness to declare, as a preface to his remarks, that "no man of sense will endeavour to attain by artifice what Nature gives voluntarily." We can never accomplish by any artificial process whatever anything half so well as Nature herself. Artificial swarm-making, therefore, must be performed, I hold, only in certain circumstances, and according, as far as possible, to natural laws. The further we deviate from these laws the less successful shall we be and the more direful the results.

These remarks being made, let me come to the consideration of the evils of which Mr. Woodbury complains. Mr. Woodbury's apiary has been literally an experimental apiary. For the purpose of multiplying Ligurian queens he has availed himself of the well-known power which bees possess (the discovery of Schirach), of creating queens at will; he has adopted every expedient to attain his end; he has checked and disallowed the natural swarming propensities of his bees; he has forced them into positions foreign to their natural habits and instincts; he has shifted and re-shifted colonies and portions of colonies with the produce of their labours again and again; he has transferred a few combs from this hive into that hive, and again from that hive, it may be, to another, until he has gone the whole round of his stocks. In the various manipulations consequent on all this work brood-combs will get sometimes, it may be, chilled by too long exposure to the cold air, or are untended to and neglected by the bees by reason of the disorders and disturbances created in the hive; and once the evil is neglected, or chilled brood occurs in any hive, then farewell prosperity—there is laid the foundation of future evils, which it is scarcely possible to over-estimate. The unhatched larvæ get corrupted in their cells, the bees do not seek to remove them if they can, the eggs laid in contiguous cells are affected by coming into contact with these cold putrid bodies, and remain also unhatched. The evils increase; the bees become paralysed, their industry is materially damped, an inertness and apathy seize the whole community, the queen participates in the effects, her reproductive powers are slackened—in short, the whole hive is affected, and becomes, if I may use the term, completely demoralised. Its numbers decrease, and it speedily arrives at that stage when it must be classed under the category of "weak and unhealthy;" and eventually, if the evils are not timeously rectified, it will become a complete wreck. Is this the state in which Mr. Woodbury's hives are now situated? If so, is it to be wondered at? Is it a mystery which cannot be solved?

If I am right in my surmises—if I have succeeded in pointing out the causes of these evils, what shall I say as to the remedy? I should advise a total clearance of all the affected combs in each hive—nay, of the whole comb together, and the bees to be introduced into fresh combs, the produce of healthy hives to be got elsewhere, containing plenty of brood and honey, and thus the evils in question will be obviated, and the sanitary condition of his stocks will be completely restored. It is vain to attempt a restoration now in any other way. The season is too far advanced for less decided measures. The case is urgent and requires immediate action. Leave the hives as they are, and not a bee will live to see the ensuing spring.

Mr. Woodbury refers to the successful bee-keeping of many who know little or nothing of the natural history of the bee. May not this be accounted for by such individuals allowing their bees to take their free, natural, and unrestrained course in swarming, and by not tampering with their instincts and interfering with their habits, not forcing them into positions which are adverse to their well-being?

In regard to differences in the reproductive powers of queens, I at one time entertained the same views as Mr. Woodbury propounds—namely, that they are rarely at fault. A more enlarged experience, however, has convinced me that these differences exist to a large extent; and though it

is foreign to the present subject to enter into a consideration of the causes of these differences, involving, as that consideration necessarily would, a discussion on the whole question of queen-rearing and fecundation, suffice it for the present to state that these differences are considerable, both in regard to the power of oviposition and to its continuance or duration. Some queens become exhausted in one year—others hold on for several years, maintaining all along their superior prolific character.

These points, I dare say, are new to most of your apiarian readers—at least they are never mooted in the pages of this Journal—but they are facts nevertheless; and if Mr. E. Fairbrother asks, as he did ask, how to choose a prolific queen, my answer to him is, that though I am myself guided in some measure by such considerations as I have here merely hinted at, yet the safest and best course for apiarians in general to follow is to be guided by actual facts:—To preserve such queens as really prove themselves to be very fruitful, and which maintain the colonies over which they reign in a state of prosperity; and to dispense, on the first fitting opportunity, with such as prove themselves the reverse.—J. LOWE.

TRUE CAUSES OF FAILURE IN BEE-KEEPING.

THE communication from "A DEVONSHIRE BEE-KEEPER," in THE JOURNAL OF HORTICULTURE of July 21st is calculated to fill the minds of other bee-keepers with apprehension and dismay. If so great a bee-master finds his stocks dwindle away and die, in spite of the most earnest attention and the most approved plans of bringing out their capabilities, what can mere novices like myself expect but sooner or later the like failure—less signal, perhaps, but none the less disappointing? If the bee-keeper's great oracle is baffled, to whom shall we look for trustworthy guidance? Most sincerely do I, in common with many others who take an interest in apiarian pursuits, regret your able correspondent's disappointment; and most heartily do I hope, that for his own sake, as well as for the sake of those who are similarly circumstanced, he may be able to discover the true reason.

At the same time I beg to state that "A DEVONSHIRE BEE-KEEPER'S" failure might have been expected to occur sooner or later. Bees must, as I take it, be treated on other principles than those which are merely scientific. You may laugh at the notions which country people have respecting these strange creatures, and call them superstitious if you will, but to use the words of a great writer—

"There are more things in heaven and earth, Horatio,
Than are dreamt of in your philosophy."

In your Number for May 6th, 1862, an article appeared on "Bee-keeping and Customs in Cheshire." It is there stated that unless the bees are expressly informed of the circumstance of any member of the family dying, the bees, too, so it is believed, will dwindle away and die. Multitudes of examples, it is said, can be alleged by the "old dames," in proof of this idea; but is not the word of the "old dames," experienced as they are, deserving of being credited? I think it is. But in reality not merely in cases of death, but in cases of family festivity, the bees should be duly made acquainted with what is going forward. If a friend is coming to stay in your house, you should inform them, and introduce him to them at the earliest opportunity. If any joyous event takes place, such as a marriage or a christening, and you entertain a party of friends on the occasion, you should by all means make your bees partakers in the good cheer provided. If you forget them, they will probably resent the affront, and desert you. But if there is one thing more than another which is said to be "unlucky" in regard to bees, it is buying and selling them. Has not our friend, the "DEVONSHIRE BEE-KEEPER," been rather a serious offender in this respect? Can we wonder that his bees have taken it to heart and failed to cheer him with the wonted signs of their goodwill? You may lay it down as an axiom that bees if affronted will cease to prosper; they will dwindle away, and ultimately, in spite of every care, die. Of course, bees must, in all cases, be properly hived and attended to, but at the same time, if certain customs are not complied with in regard to them, I believe that the greatest amount of

attention, and the most approved hives, will not suffice to insure success.

It is notorious that the bees of one proprietor will sometimes prosper, while no care on the part of another, living possibly close by, will command an amount of success sufficient to repay him for his pains: hence it is a very common idea among cottagers all over the country, that the prosperity of bees depends as much on what they call "luck," as it does on anything. If, they would say, the "DEVONSHIRE BEE-KEEPER" is going to have a run of ill-luck with his bees—whatever may be the cause of it—do what he may, they will not prosper. My own belief is, that he will find them dwindle to that extent that he will have scarcely a bee remaining, and, therefore, I should advise him, little as I am qualified to give advice on the scientific management of bees, at once to get rid of his entire stock, and start afresh. Let him beware of offending the moral susceptibilities of his bees, English or Italian, in any way, and then, probably, he will succeed as in times past.

Probably he will treat all that I have said as "bosh," but I could not help suggesting it for his reflection. At any rate, it is plain that he has a problem to solve as difficult as any that has hitherto engaged his attention in regard to bee-keeping.—JONAS JACKSON.

[Every apiarian must agree with Jonas Jackson; and to his suggestions we will add a few more similarly sanctioned by antiquity. As Mr. Woodbury will like to strengthen his hives by the joining to them fresh swarms, therefore let him kill a bullock as directed by Virgil in his fourth Georgic, and let him add the bees engendered by its bowels to his declining stocks. Let him in future on the death of any relative tie a piece of black crape round each bee-hive, as they do, or used to do, in his own county, as well as in Gloucestershire and Cornwall. When his hives swarm in future, let him cry "Brownie! Brownie!" summon the tutelary fairy to his aid to prevent their going whither he would not. Never let him again part with a hive of bees for money, and when he barter one away never let him have it removed on any other day than Good Friday.—Eds.]

FAILURES IN BEE-KEEPING.

WHILST condoling, as in duty bound, with our brother of Devonshire, I would remind him of one of olden time (steadfast in his integrity when brought level with the dust from a lofty pinnacle of prosperity), of whom it is recorded that he had given to him "twice as much as he had before." No doubt your readers will all respond to the hope, and wish that the "DEVONSHIRE BEE-KEEPER" may soon be himself again, and his hives prospering even beyond the success of yore.

I should rejoice could I point out the reason why such failures take place in apiculture as our leader is now in mourning for. I know such deaths and losses are most frequent; witness the number of apiaries on every plan, once flourishing, but now exhibiting only "a beggarly account of empty benches." But I cannot. I know that certain families of the human race die out, why and wherefore it is not possible to say, and strangers almost take the name, titles, and properties of those who have been as wishful to perpetuate their line and name as the "DEVONSHIRE BEE-KEEPER" was or can be to keep up the stocks in which he prided. Equally pleased should I be could I point out the reason of the potato failure. But I cannot: I only know that worms will wither our gourds in a night. I believe all these losses and mishaps, if you will, are ordered and permitted by One who doeth all things well; therefore, I faint not when I have my share of the mischances, and I try to follow the example set me by my favourites, which always endeavour to rectify their "break-downs" as long as there is any hope left of building up again.

When I brought my bees from the north of Lincolnshire (three hives) in the winter of 1861 and 1862, I thought they were all "good standards." Two were swarms of 1861, the third an old stock that had not swarmed that year. They all began the decidedly bad bee-season of 1862 vigorously enough; but the third soon began to dwindle away, leaving honey enough to have wintered two hives. Of the other two

only one just "saved its bacon" by a trip to the moors. The other swarmed twice, and I kept it at home, giving it honey without measure all the time its partner was at the heather; and now mark the result. The hive I kept at home followed suit exactly this spring with the one which died in the previous one, and the other so nearly dwindled away, that I was once on the point of "killing it to save its life." I did not do so, however, and, strange to say, it has recruited; and though it never has been full of bees in any period of this summer it has made plenty of honey, and is now one of the heavy ones of my thriving stocks. I never observed one drone issue from it all this season. I never saw one within its windows; but one night I found the front of it strewn with drones, some dead, some dying, some in all stages of infante life. I have my idea that this hive will do no more good, and it is now doomed to the fuming-pot. In Yorkshire I had a similar case exactly. The heaviest hive I had I deprived of a portion of its honey, and the next season it dwindled away.

I could give instance after instance of the kind, both under the depriving system and on the cottage plan—first swarms, seconds, old stocks, all alike; sometimes a hive or two in an apiary, sometimes the whole lot. The simple look on and wonder, the wise are confounded, the superstitious say it betokens death, or is the consequence of it; but as I do not like to class myself with either of those denominations exactly, I say with him of my neighbouring county, we have not arrived at the solution of the mystery. I should have been almost cleaned out again last year, as I have been many a time before, had I not purchased two first swarms. Of these, one was, to all appearance, doing as well as bees could do last season, when one morning I saw that something was amiss—the bees were showing every symptom of having lost their queen, though full of brood-comb in every stage. Whilst the hubbub was at its height a neighbour had a "second cast." I was not long in looking out for a supernumerary queen. I caught one, took her home to my "distressed manufacturers," and in less than one minute after this young virgin stranger entered the hive they were working away as steadily and happily as I should wish those of Lancashire to be working, were the cotton famine at an end.

One of your correspondents asks respecting the length of time piping is heard before the issue of a swarm. I have known them do it a day or two after the first trump of defiance. This year they have piped for seven days or more. More than a fortnight elapsed between the first and second swarms in my garden. In a neighbour's, some of his hives swarmed for the third time on the seventh day. So much for riddles. It would almost appear as if bees did not adhere very strictly to them. But here an ignorance of their habits may put us at fault.—THE HAMPSHIRE BEE-KEEPER.

A WHITE OUSEL.—A very interesting variety of the Ousel (Blackbird) has been shot near here; it is evidently a male bird, and is a pure white—so much so that I could not discover a single feather varying in colour. Its yellow beak added to its singularity of appearance.—W. EARLEY, *Digswell*.

OUR LETTER BOX.

LANE CHICKENS (A Constant Reader).—You will find remarks on this subject in another column.

STORING HONEY—ITS USE (J. T., *Stockport*).—Store your honey in closely-covered jars, not in tins, which would communicate to it an unpleasant flavour. Virgin honey in the comb is no mean adjunct to the breakfast table, nor is it to be despised when newly drained from clean combs.

KILLING DRONES (J. F.).—On no account kill them. The bees will effect the slaughter when the drones are no longer required.

LONDON MARKETS.—AUGUST 3.

POULTRY.

London is fast becoming empty. Demand flags and supply increases. Prices suffer accordingly.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 73.8°, and its night temperature 50.9°. The greatest heat was 92°, on the 11th and 15th, 1842; and the lowest cold, 32°, on the 13th, 1839. The greatest fall of rain was 1.14 inch.

ARCHERFIELD EARLY MUSCAT GRAPE.

WITH regard to this I consider it right—more particularly towards the Fruit Committee of the Royal Horticultural Society—to state that, after having tested this Vine under various circumstances, the plants propagated from the original Vine do not maintain the peculiarly early character which it has exhibited for three successive years. It will, of course, be taken for granted that this will

prove a disappointment to all concerned; for the prospect of having acquired a Muscat Grape that would ripen as early as the Black Hamburg, even in Muscat heat, was one of great importance. So far as the perpetuation of the very early character of the original Vine is concerned, I am sorry to say the matter is now hopeless, and, to my mind, settled to the contrary.

I have already publicly stated the Vine was no seedling of mine, and I was in ignorance of its history. It was planted in 1860, and in 1861 was allowed to carry a few bunches; and so early was it that I several times expressed my conviction that it could not be a Muscat at all. When it ripened all doubt on this point was dispelled; and from the attention that it attracted from all who saw it ripe while the others were green, I was induced to send it to the Fruit Committee to see if they knew what it was. In 1862 the eyes that were taken from it were put in along with Black Hamburgs. Royal Muscadine, Muscats of sorts, as well as other varieties; and under precisely the same circumstances, the buds from this mysterious Vine were ready to pot-off long before any of the other varieties. Last year and this the original Vine, as many could testify, exhibited its peculiarly early properties as strikingly as ever.

There were the strongest temptations for its being distributed this year, but from the mystery which existed about its origin I was determined that not a shadow of doubt should be left as to its character before I could allow its distribution. To set the matter at rest there were a good many grafted on the old Muscat of Alexandria in a house entirely apart from the parent Vine, and one was put on the Muscat that grew next the original Vine in the same house. There were plants of it planted at Dalkeith Park gardens in a house where several other varieties of Muscats were planted of a like age, and it was grafted on other Muscats there also, all with the view of proving whether under different circumstances the early character would be perpetuated. Under these circumstances it has not proved any earlier than the earliest of the other Muscats against which it has been tested. In a late Muscat-house here, where the various sorts are now changing colour, the fruit from

the inarches of last year are no earlier than that which is borne by the other varieties planted in 1860. The original Vine never grew as strong as the others; and probably something may be discovered that has affected it, and perhaps a lesson may be learned in the early ripening of Muscats. However, it is not my present object to theorise on the matter in relation to the results produced. Meantime I am satisfied with stating the facts of the case, and will notice with interest the Vine which has hitherto been so remarkably early in its produce.

I may state that it appears under the different circumstances related above to be much more free in setting and stoning than the old Muscat of Alexandria, but not more so than the Bowood and Tynningham Muscats, while in bunch and berry it resembles the former more than the two latter. D. Thomson, *Archerfield Gardens*.

BEDDING-OUT AT THE CRYSTAL PALACE
IN 1863.

I HAVE paid two visits this season to the Crystal Palace for the express purpose of gaining as much information as I could from the bedding-out there. My first visit was at the beginning of July, and my second in the last week of that month.

Some of your readers may not be aware, or have forgotten, that Mr. Beaton stated last year in No. 82 of your Journal that some of his new seedling Geraniums would be tested this summer both at the Royal Horticultural Society's gardens and at the Crystal Palace—such as Cybister or The Tumbler, Mrs. Whitty, Crimson Minimum, and others unnamed. As I had heard, also, that there were to be several new things, or, rather, old things revived, but which to me were new, on my first visit I was glad to have the aid of Mr. Page and Mr. Vyse, the superintendents of the Rose Mount and the upper terraces. I was afterwards fortunate in meeting Mr. Gordon, who was kind enough to verify some of my notes upon his bedding-out, and who also showed me a new Lobelia of his own raising, which for size of flower and colour beats our old Lobelia speciosa hollow.

In order to enable you to follow me to the different beds I must beg you particularly to notice that I begin with the first round bed facing the entrance to the gardens from the railway station.

Suppose you have given your entrance-fee, and are standing on the top step of the doorway directly facing the Rose Mount, your eye is caught immediately by a lovely coronet of pink, scarlet, white, yellow, and blue, which forms the decoration round the upper part of the Rose Mount. Bring your eye down to the base of the Mount to the walk which goes round; directly facing you is a path leading up to the top of the Mount, and it is to a bed on the left-hand side of this path, but on the right of the walk going round the Mount, supposing in your course of inspection the Mount is on your right, that I wish first to direct your attention. It is a round

bed planted with *Sidonia* for centre, one lovely mass of pink; then one circle of Harry Hicover, the outer circle being *Lobelia Paxtoniana*: this bed strikes me as one of the most perfect in the gardens. Some, perhaps, would prefer a rather broader circle of Harry Hicover, but you must remember Harry is a new comer, and his progeny are not as yet very numerous. *Sidonia* is a *Geranum* which I am surprised is not more used. For bloom it far surpasses Christine; but it is rather difficult to get up a stock of, and must be planted very close; old plants are also the best. There are several of the breed in the market, but this is the true one. Remember, this *Sidonia*-bed is our starting-point. Now if you will be kind enough to take your way as if going up to the Palace by the walk round the Mount (thus the Mount will be on your right), you will come to another round bed planted with *Tropaeolum elegans* and *Golden Chain* round—a bold stroke, orange and yellow! but forming a very good contrast to the first—viz., the *Sidonia*, and to the next. This is planted with another new *Geranium*—*Baron Ricasso*, as a centre, a circle of two rows of Christine, a circle of one row of old *Floribunda Geranium*, the outer circle or edging being *Lobelia speciosa*. The *Baron* is much the same colour as *Harkaway*, but brighter and with much larger petals and truss, and a far more abundant bloomer: it has a slight horseshoe on the leaf. The old *Floribunda* is a friend of my youth. I remember a ladder plant of it 2 or 3 feet high, which annually decorated our nursery window. It propagates easily, and, if the old blooms are picked off, flowers well during the whole summer; but if you will take my advice, use it only as an inner circle or centre and not as an edging, as when the white petals drop off they make a sad litter.

We now come to another path leading up the Rose Mount. At the corner formed by this and the walk going round, is a heart-shaped bed, with a centre of *Trentham Rose* and *Aurea floribunda Calceolaria* as an edging. Turn now up the walk leading to the top of the Rose Mount; and next the heart-shaped bed at the corner, on your right going up, is a very charming bed. I call this a salad-bed, for it has the same kind of fresh cool appearance. It would form a very good neutral tint to bring in between stronger combinations of colour. It is planted with alternate circles of *Lobelia Gordoniana*, and *Alma Geranium*. Up again two or three steps, and still looking to the right, you have a bed of dark maroon *Calceolaria* (seedlings of Mr. Gordon's, very beautiful at my first visit, but fallen off on my second, owing, no doubt, to the excessively hot sunny weather), with an edging of crimson Ivy, far too narrow, and not the right colour to put next to the *Calceolaria*. And now turn back again and go down the walk, and you come to another salad-bed on the right, opposite the other, planted with *Julia* variegated *Geranium*, and *Lobelia Paxtoniana*. This *Julia* was brought out by Turner or Kinghorn, and, as you will probably notice, is superior to *Alma*. At the corner opposite No. 1 heart-shaped bed, is a round bed, centre *Prince of Orange Calceolaria*, with an edging of *Harkaway*.

Now, you are again in the walk going round the Mount, and at the next bed you exclaim, "Oh, how dull-looking!" It is an attempt to make the *Fuchsia* *Queen of Hanover* as a bedding plant, and is planted with *Fuchsia* *Queen of Hanover* for centre, two circles of *Empress Eugénie Verbena*, one circle *Fuchsia Globosa*, edging a white *Lobelia*.

We now come to No. 2 heart-shaped bed, planted with *Crystal Palace Scarlet Geranium*, with an edging of *Flower of the Day*. Continuing your course you come to a large bed planted with *Rhododendrons*, and next to No. 3 heart-shape, with a centre of *Purple Nosegay*, bordered with a hybrid *Geranium* called *Lady Mary Fox* and edged with *Tropaeolum Elegans*. Close to this No. 3 is a tree with a seat under, and a walk runs up the Rose Mount. Up this walk I shall not take you, as there is nothing particular to notice, the beds on both sides being made up of mixtures of small variegated *Geraniums* and *Verbenas*, which last have failed. You may, perhaps, notice the edging of the first round bed on the right of the walk. It is *Golden Ivy-leaf Geranium*. The round bed at the corner is filled with *Tropaeolum Ball of Fire*.

Proceed now along the circumference-walk, always keeping the Mount on your right, and you come to a round bed filled with *Gazania splendens*, mixed with *Cerastium*

Biebersteinii, edged with *Cerastium tomentosum*. The next is a very bright bed, centre *Brilliant Geranium*, edged with *Agathæa coelestis variegata*. Then, there is another attempt with *Fuchsias*. We now come to No. 4 heart-shape bed, centre *Punch* four rows, encircled by two rows of *Gaines' Yellow Calceolaria*, two of *Christine*, the whole edged with *Purple King Verbena*—a very effective bed. Now, turn up the walk to the top of *Rose Mount*, and on your right you have a bed centred with one of the new *Nosegays* of much the same colour as *Trentham Rose*, a capital bloomer, edged with *Blush Minimum Geranium*. The next bed is variegated *Geranium Bijou*, mixed with *Eyebright Verbena*, edged with *Lobelia Gordoniana*.

Turn down again, and with your back to the *Rose Mount*, you have on your right a bright rosy-coloured *Verbena*, a new seedling edged with *Shottesham Pet Geranium*. Now you come to my pet bedding *Geranium*, *Lord Palmerston*, for centre, with an edging of *Blush Minimum*. *Lord Palmerston* is equal in truss to *Stella*, but of a more crimson colour. I measured some of the petals, they were 1½ inch in length, and you will find it difficult to count the buds on a truss. The next bed is filled with a dull-looking double *Tropaeolum*, edged with *Gnaphalium lanatum*. You are again in the circumference-walk; continue along it passing two or three round beds, one of which is *Roses*, till you come to No. 5 heart-shape, centre *Cottage Maid*, surrounded by *Christine*, edged with *Gnaphalium lanatum*.

Then comes another walk leading up the Mount, up which it is not worth while to go. Opposite to No. 5 is another bed of Mr. Gordon's dark *Calceolarias*, edged with variegated *Crimson Minimum Geranium*. Pass along the circumference-walk, and the first bed is *Queen of Hanover Fuchsia*, edged with *Cuphea*; next bed is *Gazania splendens*, edged with *Arctotis reptans*, a new edging plant; next, a bed of *Heliotrope* mixed with *Verbena venosa*; and next, *Rollison's Unique Geranium* edged with a seedling white *Verbena*.

We now come to the sixth heart-shape bed, *Trentham Rose* as a centre, round which is *Aurea floribunda Calceolaria* two rows, edged with *Purple King Verbena*. Now up the *Rose Mount*, and the first bed on your right is, centre *Eyebright Verbena*, edged with *Lobelia Paxtoniana*. The next is a very pretty bed made up of *Lady Plymouth* variegated *Geranium*, mixed with *Melindres Verbena*, and edged with *Cloth of Gold Geranium*. On the other side of the walk going down again, you have on your right a counterpart to the last in a bed filled with *Dandy Geranium* mixed with *Verbena Hendersoni*, and edged with *Cloth of Gold*; then a bed with a rosy-crimson *Verbena* not named, edged with *Lobelia Paxtoniana*; and the round bed at the corner is *Tropaeolum elegans*, edged with *Gnaphalium lanatum*.

And now along the circumference-walk and you have a splendid bed of *Brilliant Geranium*, edged with *Golden Ivy-leaf*. The next bed is of a dull-coloured *Petunia*, edged with *Nierembergia*. Then a bed of *Calceolaria Prince of Orange*, edged with *Golden Chain*; and the last, *Gaines' Yellow Calceolaria*, edged with *Floribunda Geranium*.

You are now at No. 7 heart-shape bed, just opposite the entrance from the railway station. It is planted with *Cottage Maid* for centre, surrounded by *Crystal Palace Scarlet Geranium*, edged with *Flower of the Day*.

We have now completed our circuit of the *Rose Mount*, and you had better proceed up the walk next to No. 7. On your right is *Trentham Rose* for centre, a circle of *Christine*, and an edging of *Purple King*. On your left going up is another of Mr. Beaton's seedling *Geraniums* of dwarf habit and an abundant bloomer. Mr. Page did not know the name, and only Mr. Gordon is in the secret as to the numbers. On the left again going up is a new *Tropaeolum* of a dark maroon tint, a seedling of Mr. Gordon's.

And now we are on the *Rose Mount*. It is planted in festoons. First, a centre of *Christine*, festooned with two rows of *Crystal Palace Scarlet*, one row of *Gaines' Yellow Calceolaria*, one row of *Aurea floribunda Calceolaria* as of dwarf habit, then two rows of *Flower of the Day*; the angles formed by the festoons being *Lobelia Paxtoniana*; the whole edged with two rows of *Lobelia speciosa*. This is one of the most showy examples of bedding-out you will see anywhere. Unfortunately *Christine* seeds too freely this dry season; but we shall have *Helen Lindsay* next year, which they say has not the same bad habit.

The six sunk beds on the top of the Mount inside the Arcades are planted in opposite pairs. The first is, centre Cottage Maid, two rows of Christine round one row of Baron Hugel, edged with *Gnaphalium lanatum*. The second pair is, centre Eclipse Calceolaria, two rows of Trentham Rose round two rows of Crystal Palace Scarlet, edged with Alyssum. The third pair, Gaines' Yellow Calceolaria for centre, two rows of Cerise Unique Geranium round two rows of Brilliant Geranium, and edged with *Cerastium tomentosum*.

The four beds round the flagstaff are, centre Cottage Maid shaded off by a circle of Trentham Rose, again shaded off by a circle of Christine, a circle of Alma Geranium, the whole edged with *Lobelia speciosa*.

So much for the Rose Mount. It has taken some time to go round, and you have seen several beds which are not satisfactory, especially where Verbenas or Fuchsias are used, but the general effect is very bright and gay.

The next beds for you to notice are those on each side of the grand central walk to the Palace. These are very striking, especially as you look down upon them from the terrace above. On the upper side of the steps leading up to this central walk the oblongs are planted with Gaines' Yellow Calceolaria for central stripe, two rows of Crystal Palace Scarlet on each side, two rows of Purple King Verbena, edged all round with Mangles' Variegated Geranium. The round beds are—centre Trentham Rose, a circle of Prince of Orange Calceolaria, edged with *Tropæolum elegans*. On the lower side of the steps the oblongs have for central stripe Calceolaria amplexicaulis, two rows of Cerise Unique, a stripe of Purple King Verbena, and Mangles' Variegated Geranium all round. The round beds are the same as those above.

Mount now to the grand terrace. The main central walk leading to the Palace cuts the grand terrace in half. At each end of the terrace are the sunk panels. We will begin with that at the west end. This, as well as the other to the east, are planted alike. The two circular ends of the four corner beds have for centre Amplexicaulis Calceolaria, with a circle of Trentham Rose, while the main part of the bed between the circular ends is planted with Cottage Maid Geranium, and an edging of Flower of the Day goes all round. The long beds of the chain pattern have for centre Crystal Palace Scarlet; the round have Christine for centre; while Gaines' Yellow Calceolaria, edged with Alyssum, forms a continuous chain round both. And now supposing we are at the west end of the grand terrace, we will take our course towards the east. On your left hand, therefore, you have a series of round and oblong beds. The oblong are filled with Rhododendrons, edged with dwarf China Roses. The round beds here, as well as in the corresponding set at the east end, have several fresh introductions for trial and criticism.

The first round bed should especially be noticed, as there are three new plants. The centre is the *Amaranthus melancholicus ruber*, a native of Japan, introduced last year by Mr. Veitch, and now used for the first time here. It requires peculiar management, or you will fail with it. Sow in heat not later than the end of January. Directly the plants are up place them in a cold frame, excluding frost. When the rough leaves appear pot singly into 48-pots, keep in a cold frame, gradually hardening-off till planting-out time, and do not be in too great a hurry for that. Till then beware of cold winds and hot sun, and when the pots are full of roots do not let them want for water. At the end of all your other bedding-out, plant your *Amaranthus*. It is one of the best of the new variegated plants for bedding, and in a mass with the sun shining beyond nothing can excel it.

Round the *Amaranthus* is St. Clair Geranium, and round St. Clair a new one of Beaton's, Black Dwarf, very effective, and a decided acquisition; the edging is Cloth of Gold. There was, and is still, a prejudice against Cloth of Gold. People said it looked unhealthy, but it is gradually gaining favour, and when its constitution has recovered its tone from forcing for propagation, it will supersede Golden Chain. It is very easily propagated from leaves. No. 2 round bed—centre, a seedling of Mr. Gordon's, like Christine, but hardly so good; a circle of Madame Vaucher growing dwarf and blooming well this dry season; edging *Lobelia Paxtoniana*. No. 3 round bed—the centre is Beaton's Magenta No. 2, a great improvement on the first of that name; a circle of Amar-

anthus, surrounded by *Centaurea gymnocarpa*; edging *Lobelia speciosa*. No. 4, the centre is *Centaurea gymnocarpa*, *Coleus Verschaffelti* next, *Quercifolium floribundum* and Cloth of Gold for edging, the *Coleus* gradually becoming like a piece of dirty flannel. No. 5, the centre another of Beaton's new Nosegays, *Amaranthus*, *Centaurea candidissima*, and *Lobelia speciosa* edging.

We come now to the oblong beds on the left-hand side looking east of the half-circle walk, which is intersected by the grand central walk up to the Palace. No. 1 is Countess of Ellesmere Petunia in a mass, edged with Golden Chain and *Lobelia Paxtoniana*. No. 2 is a seedling *Tropæolum* of Mr. Gordon's, of a yellow colour, but with blood-red spots, which may lead to our having some day a red *Tropæolum*; edging Alma Geranium and *Lobelia Paxtoniana*. No. 3 is a central mass of Geranium *Candidissimum*, very much like Madame Vaucher, edged with Golden Chain and *Lobelia Paxtoniana*. This edging is repeated alternately with Alma for the remainder of this set of beds. No. 4, central mass, dark orange Calceolaria seedlings. No. 5, centre *Tropæolum elegans*. No. 6, Prince of Orange Calceolaria. No. 7, centre Comte de Morny Geranium, a new one of the horseshoe race, and very good.

The circular beds surrounding the pedestals of vases and statues are planted alternately. First, for central circle three rows of Trentham Rose, one row of Christine each side, and Flower of the Day for inner and outer edging. Second, for central circle three rows of Christine, one row of Crystal Palace Scarlet each side; edging same as the first. Mrs. Whitty, which some say is to supplant Christine as a pink bedder, is planted in the first oblong bed after you have crossed the grand central approach to the Palace, supposing you are still going east and along the great half-circular walk. The dry season has had the same effect on it as on Christine—the flowering of both is spoilt by their seedling. Then we have another mass of dark seedling Calceolarias, and then a bed of Lord Palmerston Geranium, which for size of truss and petal and glow of colour is not yet beaten.

A bed of Verbena Great Eastern, and one or two others, and you are now on the grand terrace. Standing with your back to the Palace, on your right are a series of round and oblong beds; the round with mop-headed Acacias, standard Rhododendrons, and two miserable-looking Cedars, which had much better be removed and planted in the middle. The oblongs have a stripe of Crystal Palace Scarlet for centre, on each side a double row of Christine, and Purple King all round. The round beds are a mass in beautiful bloom and health, notwithstanding the trees, of Aurea floribunda Calceolaria edged with Flower of the Day.

Continuing your walk eastwards along the grand terrace you have a set of round beds alternately with Rhododendrons, almost repetitions of those at the west, except the last of all, which is worth your inspection. It has for centre, *Amaranthus*, then a circle of St. Clair, surrounded by a new Geranium of Italian origin, I was told, called Lucien Tisserand—a perfect beauty; the edging is Cloth of Gold.

At the Crystal Palace, as at many other places, the season of 1863 is looked upon as a bad one for bedding plants. Contrasting with the two previous, which were noted for continual wet, this has been the driest known for years. Bitter cold nights have also left their marks on our flower-beds.

The new bedding plants for the year which have proved themselves acquisitions are the various Nosegay Geraniums raised by Mr. Beaton, among which, as named, are Lord Palmerston, Black Dwarf, and Magenta No. 2, not forgetting the Golden Ivy-leaf and Lucien Tisserand. The *Amaranthus*, as Mr. Robson predicted, is a great acquisition, and *Centaurea candidissima*, so far, is likewise a gain; but *Coleus Verschaffelti* is sentenced to perpetual imprisonment in the greenhouse.

F. W. ADEY, *The Cell, Dunstable.*

DISEASE IN THE GLADIOLUS.—In many of the largest collections of Gladiolus round London a disease has made its appearance, which is affecting the plant very much in the same way as the Potato disease has attacked the Potato for some years past. The leaves gradually lose colour and die-off as if the growth were over and the roots matured, and all this without the flower-spike having ap-

peared. We shall be glad to hear how far the collections in the country have been affected, and if any remedy has been discovered to arrest this threatened calamity to one of our most ornamental autumnal flowers.

KEW GARDENS.—August 1.

"Hast thou e'er seen a garden clad
In all the robes that Eden had?
Or vale o'erspread with streams and trees,
A paradise of mysteries?
Plains, with green hills adorning them
Like jewels in a diadem?"

The entrance gates from Kew Green are worthy of notice. The piers are of Portland stone, with moulded and sunk panels. Those of the large piers contain elaborately carved falls of flowers and fruit. The frieze is also enriched with swags of flowers, &c., festooning on each of the four sides from rams' heads projecting boldly from the angles; and the cornice is surmounted by a richly carved vase containing a bouquet of flowers.

To the right upon entering is the Grecian conservatory; but as my object is to describe the summer tenants of the beds, I will hurry to the first turning on the left, and at once emerge upon the broad walk, on both sides of which are ranged the beds on grass. The first pair, one at each side, is a circle planted with Brilliant Geranium, edged with *Koniga maritima variegata*, more commonly known as Sweet Alyssum. The opposite bed is planted with the same to match. 2nd, Oblong bed, *Calceolaria amplexicaulis*, edged with Purple King; the opposite to match. To obviate repetition it is to be understood that every bed to be described has an opposite bed of the same to match. 3rd, A circle planted with the same as first. 4th, Oblong centre, Purple King Verbena, then *Tropaeolum elegans*, edged with *Cerastium tomentosum*. 5th, Circle, *Koniga maritima variegata*, edged with *Lobelia speciosa*. 6th, Oblong, Panch Geranium, edged with *Gnaphalium lanatum*. 7th, Circle, the same as 5th. 8th, Oblong, standard and dwarf Roses. 9th, Circle, Purple King Verbena, edged with *Tropaeolum elegans*. 10th, Oblong, centre *Ageratum mexicanum*, then *Cerise Unique Geranium*, edged with Purple King Verbena. An incident occurred here: As a respectably-dressed party was passing, one of them stopped to inquire of another companion the name of the *Ageratum mexicanum*. The young lady, with the air of the knowledge of a professor of botany, told him, without the least hesitation, that it was a *Heliotrope*! The authorities at Kew and elsewhere give the public more credit for their knowledge of the names of plants than they deserve, and therefore it may be well to suggest here the advisableness of attaching the names to the bedded-out plants. 11th, Circle, the same as No. 9. 12th, Oblong, centre *Calceolaria amplexicaulis*, then *Perilla nankimensis*, edged with *Centaurea candidissima*. 13th, Circle, centre *Koniga maritima variegata*, then *Gazania splendens*, edged with *Lobelia speciosa*. 14th, Oblong, Lord Raglan Verbena, edged with *Cerastium tomentosum*. 15th, Circle, the same as No. 13. 16th, Oblong, standard and dwarf Roses and Mignonette. 17th, Circle, scarlet Geranium, edged with *Stachys lanata*. A broad walk branches off with two pairs of beds at each side; the first, an oblong, centre three rows of Flower of the Day Geranium, then three rows of Brilliant Geranium, edged with Purple King Verbena; the second, a circle, *Dahlia Purple Zelinda*, edged with yellow *Calceolaria*. 20th, Circle on the main walk, the same as No. 17. 21st, Oblong, standard and dwarf Roses. 22nd, Circle, centre *Koniga*, then *Gazania splendens*, edged with *Lobelia speciosa*. 23rd, Oblong, Lord Raglan Verbena, edged with *Cerastium tomentosum*. 24th, Circle, the same as No. 22. 25th, Oblong, centre three rows of *Calceolaria amplexicaulis*, then two rows of *Perilla nankimensis*, edged with *Gazania splendens*. 26th, Circle, Purple King Verbena, edged with *Tropaeolum*. 27th, Oblong, centre three rows of *Ageratum mexicanum*, then two rows of *Cerise Unique Geranium*, edged with two rows of Flower of the Day. 28th, Circle, the same as 26. 29th, Oblong, standard and dwarf Roses. 30th, Circle, centre *Koniga maritima variegata*, then *Gazania splendens*, edged with *Lobelia speciosa*. 31st, Oblong, Panch Geranium, old plants pegged down, edged with *Gnaphalium lanatum*. 32nd, Circle, the same as 30. 33rd,

Oblong, centre Purple King Verbena, then scarlet *Tropaeolum*, edged with *Cerastium*. 34th, Circle, Brilliant Geranium, edged with *Koniga maritima*. 35th, Oblong, *Calceolaria Aurea floribunda* and *amplexicaulis*, edged with Purple King Verbena. 36th, Circle, the same as 34.

In front is a large circle. It is 36 feet in diameter, has a rich, massive, and moulded edging of terra cotta 15 or 18 inches high. The bed is raised up as a pyramid, and in the centre is a very handsome flower-vase with pedestal and plinth. The planting of the bed reaches up to the very plinth. The centre is planted with scarlet Geraniums interspersed with *Perilla*, then *Centaurea candidissima*, then Purple King Verbena, the whole edged with Tom Thumb Geranium. The vase in the centre is filled with scarlet Geraniums. Beside the walk to the left is a bed of some length, to correspond with the sweep of the walk. The centre is filled with Flower of the Day Geranium divided into compartments, being crossed with *Perilla*; the sides are filled up with *Tropaeolum*, edged with *Koniga* and blue *Lobelia*.

On the right to the Palm-house the first is a circle, centre Purple King Verbena, then Prince of Orange Geranium, edged with *Arabis lucida variegata*. 2nd, Oblong, centre *Calceolaria amplexicaulis*, then Brilliant Geranium, edged with *Gnaphalium lanatum*. 3rd, Circle, the same as No. 1. 4th, Circle, *Ageratum*, edged with *Tropaeolum*. 5th, Half-circle, *Perilla*, edged with scarlet Geranium. 6th, Circle, the same as No. 4.

We now take up our position on the centre of the terrace in front of the Palm-house, overlooking the terrace garden. Two vases stand in front, and other vases at the head of the lake are all filled with scarlet Geraniums. The two large circular beds in the middle compartment are divided into eight parts by rows of *Perilla*, two being filled with *Calceolaria amplexicaulis*, four with Purple King Verbena, and two with scarlet Geraniums in opposite beds.

On each side of the oblongs, in the centre, is a gorgeous pattern—the centre bed planted with Christine Geranium, then *Koniga maritima*, then Dandy variegated Geranium, with *Koniga* edging. Then the figure like a bishop's crosier is planted near the handle with Purple King Verbena, then *Aurea floribunda Calceolaria*, finishing at the top with *C. amplexicaulis*, edged with blue *Lobelia*. Then a pentagon figure is planted with Lord Raglan Verbena, with the opposite bed of the same to match. The long beds north and south of the figure are composed of Brilliant Geranium, edged with Flower of the Day. The saddle-shaped beds east and west of the figure are planted with Nosogay Geranium and *Perilla*. The four corner beds at the angles are planted with Tom Thumb Geranium. The triangle beds in front of these are planted with *Koniga maritima variegata*; and the circle at each end with Golden Chain Geranium, edged with *Lobelia speciosa*. The other half of the terrace garden is a duplicate of the above.

On the south front of the Palm-house is a broad walk with chain borders on grass. 1st, A Yew tree in a circle filled up with *Tropaeolum elegans*. 2nd length, Purple King Verbena, edged with *Koniga*. 3rd, An oblong with *Perilla* in centre, then a row of Panch Geranium, and then a row of Tom Thumb Geranium, edged with *Koniga*; and so with the other beds and circles, each bed furnished with some one of the Holly trees of different-coloured foliage. On the left is a high grass mound, having in the centre an *Araucaria imbricata* encircled at some distance with two half-moon-shaped beds planted with *Calceolaria amplexicaulis* and *C. Aurea floribunda*, edged with *Koniga* and blue *Lobelia*, and on the inner or concave side with a row of Brilliant Geranium edged with *Perilla*. Beside the half-circular walks are oblong beds, some with Hollyhocks in the centre edged with Ribbon Grass, others with *Canna indica* edged with Ribbon Grass; some with Dahlias edged with *Calceolaria Aurea floribunda*, others with Fuchsias edged with *Perilla*, &c.

From the botanic department to the new conservatory is a broad grass ride, planted on one side with standard mop-headed Robinias—unsightly objects, liable to serious damage from high winds.

On the right after entering the pleasure ground is the Pantheon built by Sir Jeffry Wyattville. Its base is elevated; the entablature is supported by four columns, and bears the

initials "W. R. IV., 1837." To the south front is a Rose garden furnished with *Aimée Vibert*, *Général Jacqueminot*, *Souvenir de Malmaison*, *La Reine*, *White Moss*, some sporting with stripes of pink; *Gloire de Dijon*, and *Devoniensis*. Tea Roses in all parts look rather indifferent, which should induce the authorities to adopt Mr. Beaton's oft-repeated suggestion of removing them altogether from the oblong beds in the main walk.

Across to the new conservatory is only a few minutes' walk. It is a substantially built and splendid erection. The two wings have been added to it since Mr. Beaton's report of the place last year. The *Araucarias excelsa* and the other large specimens, for the protection of which this crystal palace was erected, are now finally planted out in a compost of loam, peat, and leaf mould. The ventilation is all that could be wished. The roof is so constructed with wheel-and-rack machinery, that one-half can slide down over the rest, so as to allow of the free admission of genial showers of rain. On the space from the great Palm-house to the Victoria-house we passed oblong beds on the grass planted with *Purple Zelinda Dahlias*, edged with *Ribbon Grass*: circles with *French Marigolds*, edged with *Purple Orach*, *Mangles' Variegated Geranium*, *Verbenas*, of various sorts, *Cupheas*, &c. Each circle was adorned with a standard Rose in the centre.

In front of the Cactus-house going eastward are two long beds each 53 yards long and 6 wide, divided at one side by a fine tree (*Negundo fraxinifolium*), throwing its wide-spreading shade over a rustic seat. The beds are planted in panels, diamond-shape, with large dots of *Perilla* in centre, next *Calceolaria amplexicaulis* and *C. Aurea floribunda*, then *Tom Thumb Geranium*, edged with *Königa*. They are splendid beds.

Although it is usual for every one to suggest improvements according to his taste or fancy, I will waive my privilege on this occasion, well knowing the difficulty of getting up stock and arranging it with taste in every minute part of an extensive place like Kew, where the visitor may wander over scenes, where, but a few years since, a wild uncultivated waste held its sway, until the genius of the place

"Stretch'd o'er the marshy vale yon willow mound,
Where shines the lake amid the tufted ground,
Raised the young woodland, smooth'd the wavy green,
And gave to Beauty all the quiet scene."

—W. KEANE.

KNOWLEDGE DESIRABLE FOR GARDENERS.

(Concluded from page 66.)

IN our last we finished with the importance of reading as a means of obtaining information, and of writing correctly as a guide for testing our knowledge, and one of the channels by which we can make our knowledge available for the benefit of others. The third essential element is Arithmetic, or a knowledge of the science of numbers. It would be well if all lads, before they enter a garden, could be well grounded in this respect. It would save them much mental labour or much mortification afterwards. We have met with otherwise bright youths who could not count above a certain number, and whose calculations, even of simple sums, had to be done by the fingers instead of by the pencil or the pen. We have also met with many who in reading, when they came to figures of any length, had to pass them over or read them just as they stood, without having the least idea of their value. The principles of notation and numeration should not, therefore, be omitted, as necessary preparations to the understanding of arithmetic.

Almost every civilised nation had its respective mode of notation. Amongst us few systems are now seen, except the Roman, which is used for dates, and by which all sums may be expressed by seven characters, as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, one thousand. There are many varieties of this mode, chiefly by reversing the 9, but into this we need not enter, as such a clumsy mode of computation, even at its best, can bear no comparison with the unique simplicity of the Arabic numerals, going from 1 to 9, and the eiphers added, by which all sums can be easily read and their value computed. The cipher of itself signifies nothing—it obtains a value by the

figure that precedes it. Every other figure represents merely of itself, from 1 up to 9, the value or quantity of a certain thing. The value of figures or units in a line will depend on their numbers, and their value is thus calculated: The first figure on the right-hand represents 0, or units up to nine, the second figure so many tens, the third so many hundreds, the fourth so many thousands, the fifth so many tens of thousands, the sixth so many hundreds of thousands, the seventh so many millions, the eighth so many tens of millions, the ninth so many hundreds of millions, the tenth so many thousands of millions, and so on to billions and trillions, of which our finite minds can form no clear conception. If in long lines of figures they will be the more easily read if, beginning at the right-hand, every third figure is marked off (,) as in the following:—

1,	2	3	4,	5	6	7,	8	9	0
Thousands of millions			Hundreds of millions			Tens of millions		Millions	
						Hundreds of thousands		Tens of thousands	
								Thousands	
								Hundreds	
								Tens	
								Units	

The figures will read thus—one thousand two hundred and thirty-four millions, five hundred and sixty-seven thousand, eight hundred and ninety.

Independently of the pleasure of reading the sum of a line of figures as easily as print, and not boggling at them, as many young people even in this enlightened age still do, the clear perception of their value, so as to place units under units, tens under tens, &c., is essential to the working-out the simplest problems in addition and subtraction, which may be considered the great rules of arithmetic, multiplication being just another form of addition, and division another form of subtraction. These matters are, however, better explained in the simplest elementary school-books than we could hope to do without taking up too much space; and after a few lessons in addition, subtraction, multiplication, and division, simple and compound, those who have the taste may well go as far as they like by private study. We have known several first-rate arithmeticians among our brother gardeners, who never got beyond the first four rules at school. They learned little more than that two and two make four, that take two from two and nothing remains, that twice two make four, and two divided by two leaves nothing over. Next to these four rules, the most essential for the young gardener to study are the rules of simple and double proportion, vulgar and decimal fractions, and the extraction of the square and cube roots, so as to measure easily all surfaces and solids.

In connection with this subject, it would be desirable to study geometry and mathematics so far as to be able to make plans of gardens, and the structures generally contained in them; and if the gardener has to superintend the erection of such, he should be able to estimate quantities required, and to measure all kinds of work according to the rules that obtain in various trades. In most works on such subjects there are regular rules for computing bricklayers', painters', glaziers', carpenters' work, &c.; but unless in moving earth, measuring trees, &c., which must be calculated by the solid (the width, length, and thickness being multiplied together), the great proportion of measurements will be merely the surface—that is, length and breadth, which if multiplied together will give the area. For measuring heights and distances, and doing much in the way of land-surveying, an acquaintance with logarithms and trigonometry will be a very great advantage; but in these days of the division of labour, the gardener who makes himself fit to be a land-surveyor had better stick to that, and give up Cabbage-growing.

Mere land-measuring, such as measuring the contents of a garden or a field, will be what most commonly will come in his way; and that will just be as simply the measuring of a surface as the measuring of the top of the table on which you take your breakfast. Of all oblongs or squares, length and breadth multiplied together give the area. In triangles, right-angled, the base and half the perpendicular multiplied together give the area. In irregular gardens or fields, with

no two sides and no two ends alike, and yet not a vast difference between them, we take the average of the ends and of the sides, and multiply them together. Thus A, B, C, D, is an irregular field of four sides, A 10, B 16, C 18, D 20. Add A and B together, which would be 26, the half or average of

which is 13. Then add C and D together, which makes 38, half of which is 19, multiply 19 and 13 together, and you have 247 for the area. A truer method, if there is much difference in the opposite sides, and one which often involves less trouble, as it saves going round all the sides, is to take the diagonal line across, A, 26, and then the two perpendiculars, F and G, 11 and 8 respectively, which added together make 19, the half of which is 9½, which multiplied by 26 gives the same sum of 247 as the area or measurement of the surface enclosed by the four outside lines. Did the field or park have a boundary, as that marked by H H H H, it is most likely we would use one of the two modes referred to for measuring the bulk or centre, and we would throw the outside into triangles, squares, or oblongs, regular or irregular, and add their contents to the centre. Straight-lined gardens and fields will ever have an advantage as respects utility, though they be less picturesque in consequence.

We have said nothing of the instruments, chains, flagstaffs, level-boards, theodolite, &c., necessary for work on a great scale; we merely wish to indicate what would be desirable, and what a man fond of figures and practice will readily master. For the same reason we have said nothing of the mode of measuring balls, circles, and other figures, because the student will find all this in the work he studies. We have introduced the above notice on land-measuring because lately we could scarcely convince a youth that an oblong garden must be measured exactly as he would the surface of a deal board—by its length and breadth.

In the few times we have had the privilege to listen to the examination of even one of our good common national or British schools, nothing surprised us more than the readiness of the scholars in mental computation, and that in difficult sums too. In such matters the schools of the present day are immeasurably superior to those of our boyhood. We can well recollect, when in the rule of three, of a whole class of us being nonplussed by the problem, "A herring and a half for three-halfpence, how many will be got for elevenpence?" Long before any of us had slated it down, a little fellow, who that day had for the first time emerged from petticoats, sung out the answer, "Eleven, sir;" and though he did not shine with the slate or the pen with figures even afterwards, he was always distinguished by the almost instinctive quickness with which he could solve even a difficult problem, merely by mental computation. The slate or the pen was quite a hindrance to him. Our young friends will find it no loss to keep up such a habit if they have obtained it, and an advantage to get it if they do not now possess it. There will be plenty of room for it in the work of every day.

In addition to the ability of taking simple plans of gardens, houses, &c., the ambitious young man will do well to cultivate and become familiar with the principles of isometric and perspective drawing. We have known some men get easily to the top of their profession, because when their employers did not know what they meant as to proposed plans, they would render all clear in a few minutes by means of a pencil and a pocket notebook. We can well imagine such a man as Mr. Robson drawing an excellent plan whilst we were writing a page. Those who have the slightest natural taste for drawing in any style should cultivate it assiduously. The late Mr. Loudon used to say that nothing could be more pleasant or agreeable, or practically useful,

Many were the advices he gave to young men to be always at it, whether it was a tool, a house, a plant, or a tree. For ourselves we never could draw a tree, we always made a muddle of it. This, perhaps, makes us think more of the man or boy who does so nicely.

We recollect the late Mr. Joseph Knight telling us that his first introduction to one of his favourite gardeners was in this wise: He called at the Exotic Nursery, where Mr. Veitch now is, and, like many more, had been knocked about a good deal, and was rather out at the elbows. Mr. Knight at that time was anxious to improve the mental training of gardeners, and drawing was one of the matters he deemed of importance. The stray wail was taken on, chiefly because there was nothing from a tool, stool, a chair, or a vase which he could not pencil off directly. One thing we are quite certain of—that the youth who so passes his leisure hours in improving himself, and, in the words of our correspondent, "fitting himself for a good situation," will, even before he enters the situation, be more than ten times repaid from the self-respect and elevated pleasure that ever attend such pursuits when humbly but perseveringly followed—pleasure that can never be known by the young man who wastes his evenings in idle gossip, stupifies his brain in a cloudland of tobacco, or resorts to sources of amusement and pleasure that will not bear the calm reflection of the following morning.

In all these cursory notes we have merely shown what a youth who has received a common education may well study with advantage, and which he must strive to grapple with, even if he knows little more than letters and figures, if he would aspire to be recognised either as an intelligent man or an intelligent gardener. As, however, we are told on rather high authority that "the proper study of mankind is man," so without overlooking at all the importance of "knowing ourselves," perhaps the next most important thing for a young gardener, after becoming a clever methodical workman, is to be thoroughly conversant with the plants which he cultivates out of doors and in-doors. This will open up at once the whole field of vegetable investigation; and in following our researches we will find that there is scarcely a science but will tend to elucidate our subject. We would encourage rather than otherwise all the legendary lore and the poetical allusions connected with plants, as in this hard utilitarian age we have need of all aids that will soften, refine, and elevate. There is something so poetical in the very diversity of plants and flowers, that almost instinctively the young gardener becomes a botanist. He wants to know the name of a favourite flower, and he studies its distinguishing characteristics. A simple introduction to descriptive and systematic botany will therefore be desirable; and for British plants we have met with nothing better than Lindley's "School Botany." By the Linnean system we collect the plants into large groups according to the arrangements of the sexual system; by the Natural system we collect them into orders according to their natural affinities. Few things can be more interesting than the pursuits of descriptive and systematic botany. To their honour be it said that there are many gardeners good botanists; and where the taste leads in this way we would not for a moment attempt to check such a pursuit. Still we must honestly state, that as a mere gardener, having mastered the first principles of systematic botany, it will be more profitable in general to study keenly what is styled phytological and physiological botany—embracing the different structures of plants, tracing the whole movements that take place from the germinating of a seed or the striking of a bud or cutting until the time comes when the plant dies from disease, age, or accident; thus including the functions of the different parts of plants, especially roots, leaves, and stems, and how these are influenced by soils, mechanically and chemically, by air, by dryness and moisture, by heat and by cold, by sunlight and shade and darkness, by diversity of seasons, varieties and peculiarities of climate, not merely as to the highest and lowest temperatures, and medium temperatures, but as to how these are conjoined with shade or bright sunshine, and altitude as well as latitude of the natural home of a plant. Without undervaluing in the least the keenest researches in systematic botany, as all will tell beneficially upon plants and gardening, we cannot conceal from ourselves that phyto-

logical botany is that which is the most important to the mere gardener, allied and linked as it is with so many other sciences. Had we time we could descant for months on this subject, and yet not please ourselves in making the matter simple and attractive. The great bulk of the writings of this serial have, by the closeness of their practical details, just tended to throw more and more light on phytological botany. We are the less inclined to enlarge on this tempting field, because so much has been well said for years; and a very good handbook can be procured from the office, "Science and Practice of Gardening," for 3s. We need not say that such a volume in our young days would have saved us borrowing and poring over expensive works, making many experiments as often unsuccessful as successful, and giving the cranium many a scratch behind the ear, when we got fairly in the mist and could see no light out of a dense cloudland.

We have said that we cannot enter on this study of vegetation without being drawn in to have some general knowledge of many other sciences. Thus, for instance, as respects the soil: we will be all the better if, in addition to the mere mechanical composition, we know its geological formation, and thus avoid many errors in culture, draining, &c. Frequently lime and other earths are driven for long distances, when perhaps a shaft of 30 feet or less would reveal near at hand the very thing wanted. There are many books on this charming theme, opening up worlds and worlds in the ages of the past; and few can read the pages of Lyell and Buckland without deep attention, but for a beginner the simple treatise of Phillips may be as interesting.

Then for the nature of soils, the character of manures as suitable to various crops, there is Chemistry revealing its wonders, and the strange transformations effected in plants—a science which no mere gardener can hope to master, but the principles of which, as applied to garden and field, we may fully comprehend from reading the pages of Liebig, and Johnston on "Agricultural Chemistry."

Again, independently of chemistry, there are many facts connected with water in its various states, with air as respects its weight, abundance of moisture, or comparative freedom from vapour, and the influence of heat as absorbed and radiated, that render a small treatise on hydrostatics, hydraulics, and pneumatics, the principles of calorific, and the still imperfect science of meteorology, extremely interesting; and even a slight study of these sciences would prevent us making some palpable blunders. A visitor lately on admiring our flower-beds, and compassionating the somewhat foxy appearance of the lawn, imagining no doubt it would please us with visions of abundance of water, concluded the condolence with—"But why not have an artesian well?" and that on the highest ground for miles round, and where now we go down the best part of 300 feet to reach water, and just now have only about 6 feet of water! We believe that now, dry as we have been, there is enough of rainfall here to meet all our requirements, could we only have means to keep the water until we wanted it. However, this season has taught us to leave less to chance for the future. A friend of ours, with large ranges of houses, was much worse off than we; but a small rivulet trilled along at a considerable distance, and by choosing a proper place, where the ground fell considerably, he secured a perpendicular fall of some 8 feet, and with that wrought a water-rum, which gave him abundance of water. We lately told how Mr. Pressley, of Knockmaroon Lodge, threw water from the river Liffey to the top of the hill by means of a wheel. Two fine places in this neighbourhood, situated on the top of small hills, are supplied by means of water-runs from streams in the valley. A lady who has one of the finest, if not the very finest, out-door ferneries in England, and who has as yet been supplied from a large tank, seriously proposes having a ram fixed in a stream from one to two miles off, and the water taken in pipes all the way. But for science, no such schemes could ever have been thought of. The pressure of the air becomes in such cases our force-pump servant.

Then, as to the imperfect science of Meteorology, how much better could we regulate our artificial atmosphere in glass houses, if we knew more of the condition of the air in almost every part of the world as respects weight, density, and the vapour contained in it. Our first lessons in this direction were derived from that fine old book, "Wells

on Dew." We have read the far more elaborate work of Daniell, and would like to have the chance of reading it again; but ever and anon we turn back to the close reasoning and the clear demonstrations of Wells; because, from his teaching we obtained a light as to the reason of many practices, and especially the whole of those having reference to the protection of tender plants, keeping heat in and cold out—in other words, preventing the radiation of heat. Mr. Wells clearly demonstrated that, properly speaking, dew neither rose from the ground nor fell from the air—that it was merely vapour condensed into water—and that, therefore, before dew could be deposited on any body, that body must first be cooled by free radiation below the temperature of the air holding the vapour in suspension; and thence it followed, that as clouds by arresting radiation prevented the formation of dew, and a sheet or a pocket-handkerchief suspended above the ground on a clear night prevented the formation of dew on the grass beneath it, just because radiation of heat was arrested, so the understanding of this simple matter makes plain all the mysteries about our modes of protection.

Again: Leaving such matters, we come back to vegetation and to the diseases and maladies to which it is subject from unsuitable climate, improper soils, and impure water, never forgetting, however, that plants, like men, live that they may die, and that deaths will take place when there is neither carelessness nor ignorance to be charged against the cultivator, otherwise our doctors and physicians would have a pretty time of it amongst us. One of the fruitful sources of the ill health and premature decay of plants arises from the attacks of the numberless insects to which they are subject; hence the importance of the study of entomology. The watching the changes and transformations of these insects is exceedingly interesting, and where there is a natural taste in that direction there will be sure to be a combination of pleasure and profit. We have had little boys destroying thousands of the white butterfly. We know the myriads of caterpillars we otherwise should have on every Cabbage leaf. We regret to say that most of the popular works on natural history do not give particulars enough for the student. Kirby and Spence is still a good introduction. A good deal of information will be found in the "Cottage Gardener's Dictionary," in Loudon's works, and also in the pages of this Journal; but a good work on insects that are injurious to garden and field, going into all the details of their transformations, and treating us all as if we knew nothing at all about the subject, has yet to be written. If our Editors would only do for us in this respect, bringing all present knowledge to bear upon practice, just as Mr. Johnson has done in the "Science and Practice of Gardening," we of the blue apron ought to raise a monument to their honour. At present much of what we wish to know is scattered through expensive works, which the humble means of gardeners prevent them from possessing.

And, lastly, though as connected with the physiology of plants rather of the first than the last importance, is the study of Geography. Every department is extremely interesting, descriptive, social, political, and physical. The poor fellow who had Dr. Johnson's Dictionary put into his hands to amuse him, might well say, "It is very good no doubt, but exceedingly dry." But there is no dryness even in general geography. To most minds its facts possess all the charms of romance, because many of its stern truths are stranger than the wildest fiction. As a subject of study, therefore, our earth with its many diversities of climate, of inhabitants and of vegetation, is well worthy of serious attention. If much time cannot be set apart to this subject, much knowledge will be, as it were, incidentally gained, if in our general reading we endeavour to get a clear idea of the country or place that comes before us. We may thus become acquainted with geography just as we have hinted that many of us have done with spelling and grammar.

However tantalising general geography may be to the gardener, that which is styled physical geography is the most interesting, connected as it is with the distribution of plants according to climate, latitude, and altitude, the great divergence in this respect of the different hemispheres, the difference between continents and islands, and how vegetation is regulated, not merely by medium, but the highest and

lowest temperatures, and these, again, by dry and wet periods, by bright light, and hazy misty light. Keeping this in view, among many introductions to geography we were much pleased with a rapid glance at one by the Rev. Mr. Heale; and among cheap atlases we were much pleased by those issued by Mr. Dower, and others, chiefly because there were sectional lines, that gave one no bad idea of the physical outline of a country. There are, no doubt, more perfect and finished atlases by Keith, and others, but at a high price. We have several times heard high opinions of Knight's "Cyclopædia of Geography," and judging from the general works of that publisher, we have great faith in it, and mean to have it some day; but a young gardener cannot easily find a couple of guineas for a single work. So far as we are concerned, we should say that for gardeners there is a want of a "Physical Geography," which at ready reference would give us many of the particulars of plants in their native homes. Perhaps the most interesting facts that have come to our knowledge have appeared in the "Horticultural Transactions," under the auspices of Dr. Lindley, who in this respect, as well as the science of gardening generally, has laid gardeners under great obligations. Perhaps the most practically useful of all that has been yet published as bearing on the physical geography of plants, are a series of tables compiled by Mr. Thompson, in the "Journal of the Horticultural Society," Parts II. and III., for 1849, giving us the names of places in almost every part of the world; the latitude and longitude of these places; in many cases the elevation of these places above the level of the sea; the mean temperature of these places for every month in the year; the mean temperature of the year; the mean temperature of the seasons, winter, spring, summer, and autumn; the difference between the hottest and coldest months; the general difference between summer and winter; the number of years in which the observations have been taken, and the hours of observation. These tables give so much the information of volumes, that we firmly believe that the great Horticultural Society could exert its power in no more beneficial way than in publishing the tables separately, with clean paper for observations between each leaf. We feel quite sure if the Society disliked doing this, though we do not see how, that if they gave leave to one of our enterprising publishers, the sale would be sure to remunerate the outlay, as at present we do not know where there is so much of physical geography, so useful in letting us know what plants from such places require, to be found in anything like the same amount of space. We would urge this all the more for our own benefit, as well as that of others, as the continued illness of our worthy coadjutor, Mr. Beaton, prevents him helping us in this respect. With his wondrous memory and vast geographic lore, which enable him to traverse the hills and dales of a country as if he had actually strolled over them in a pedestrian tour, we had strong hopes that he would do for physical geography, as respects the culture of plants, quite as much, if not more, than he did for elucidating the mysteries of cross-breeding and hybridising. We do hope that he will yet be amongst us, ready to answer as well as to instruct, and then this peculiar branch will engage a share of his attention. Meanwhile there is every inducement to the young gardener to take every opportunity of storing up facts connected with physical geography.

In conclusion, we must apologise for the random nature of these remarks, indicating rather what is most worthy of attention than telling how such knowledge is to be gained. That would be to make a cyclopædia rather than an article, and we have found time merely to write the above rapidly. In addition to all the simple things we have said, we would, as a parting legacy to our young friends, say—"Be courteous, and sensitive as to the feelings of others." It is commonly reported that perhaps the most honoured gardener of the age owed the grand step of his advancement to his courtesy and good manners. A nobleman had asked him for a beautiful Rose-bud, and in cutting it he *carefully removed all the prickles with his knife* before presenting it and the thoughtfulness and gracefulness of the act was not forgotten. It may be all a myth, as many such tales are; but the grace and attractiveness of kind courtesy will ever be facts to attract, let rough unmannerly people think and act as they may.—R. FISH.

A WORD IN FAVOUR OF THE SCARLET AND ZONALE PELARGONIUMS

AS RESPECTING THEIR POSITION IN THE EXHIBITION SCHEDULES FOR 1864.

Now that the summer exhibitions have taken place and passed away, there is a resting time for exhibitors, and all who are interested in the display of plants and flowers, calmly to consider what may be done while preparing the schedules of our great exhibitions for 1864 to render the exhibitions more attractive, and to suggest such improvements as will further the objects and interests of horticulture. It is notorious that for the last few years little or nothing has been done to vary the routine of the schedules; and it has been very frequently remarked during the past season that there was a great sameness in the plants exhibited; that certain collections carry off the same prizes wherever they are sent. The same awards are annually offered; and it is a well-known fact that plants, after receiving awards at one exhibition, have been left under the care of the officials of one society till they were required for competition at another, where they have also obtained similar prizes. Now no reasonable person will say that this system can in any way promote or forward the interests of horticulture. The public begin to remonstrate at such proceedings, and justly call for a reformation.

There is, however, it must be admitted, some difficulty in obviating this objectionable state of things; and it can only be overcome by ignoring all precedents, and entering, regardless of individual exhibitors, upon a new system. All selfishness must be abandoned, and a mutual desire to make our horticultural meetings more attractive must be the sole and true motive for action. These remarks apply to every society whose object it is to promote horticulture. It would be well to ask whether it is necessary that such large collections should be required and such high prizes offered, or at any rate be repeated, for the same class of plants during the season. We are treading now upon tender ground; and it may be said with much propriety that the cost of growing these specimens is very considerable, and that the remuneration in the shape of prizes is not at all adequate to the time and care devoted to their cultivation. But surely this is not altogether a question of pounds, shillings, and pence: more noble and generous motives must be assigned to the professional exhibitors.

There is a satisfactory pleasure and an honourable emulation among our principal professional exhibitors, which induces them to endeavour to take a high position in the horticultural world. By way of suggesting something new and desirable to be inserted in the schedules of 1864, let us take one class of plants alone, which have been hitherto overlooked and neglected. Here much interest would be excited, and an entirely new feature be introduced, by offering prizes for the various classes of the Scarlet and Zonale Pelargonium. It is easy to imagine what a brilliancy they would add to our later exhibitions when flowering plants have become scarce. Were they shown under the same restrictions as the ordinary Pelargonium they would be equally worthy of cultivation. There is a great variety of foliage and colour, and if classified and exhibited as scarlets, salmon (rose or pink), and white, the effect would be most beautiful.

It is much to be desired that our principal Pelargonium-growers would give this suggestion their attention, and that they would commence at once, while they have much spare room in their houses, the necessary and preliminary training of specimens. It is impossible to overrate the beauty of well-grown specimens of this class of flowers, many of the best varieties of which are at present unknown to the floral world. Let Messrs. Turner, Fraser, Henderson and Bull set the example, and it will be immediately followed; there are many admirers of the Scarlet Pelargonium who will be ready to contribute their aid. If the councils or managers of our societies will offer liberal prizes for competition, a most interesting and at least one novel feature will be gained for the exhibitions of 1864.

THE FROST ON THE 19TH OF JULY in this neighbourhood was severe, sufficiently so to cut-off the Kidney Beans and

the Scarlet Runners. Some Cucumbers growing in the open ground, I find, are too much injured ever to do any good. The Potatoes, also, were quite blackened; and one of my workmen informed me he saw some ice the thickness of an old shilling.—W. D., *North Essex*.

NOTES ON GARDENS PUBLIC AND PRIVATE.

NO. I.—MESSRS. IVERY & SON'S, DORKING.

THE traveller by the South-Eastern line from Redhill to Reading must have noticed—unless he has been in that somnolent state one too often sees railway travellers in—the very beautiful character of the valley through which he passes between Reigate and Guildford. Watered by the little river Mole, its alluvial soil gives evidence of its fertility in the luxuriance of the vegetation and the fine quality of the timber; while the hills, rising high on either side, are surmounted by the residences of men of fortune, whose mansions are so numerous throughout the county of Surrey. Midway in the valley lies Dorking; and to Dorking, on one of the bright and glorious days of this most sunny summer, my steps were bound. I had long threatened, and now determined on fulfilling my threat, to visit the nursery of Messrs. Ivery & Son, known to me from my early days as identified especially with the Azalea; and in these days of Fern-culture remarkable for what our French neighbours call a *spécialité* of hardy Ferns, more particularly those belonging to our native isle. Wherever Messrs. Ivery have exhibited their unique collection of British Ferns it has elicited unqualified admiration, and I was anxious to see them in their home; and so my visit was to the home nursery, situated close to the quaint old town, where everybody seems to have been determined to have a house unlike his neighbour, and assert the independence of a true Briton in doing as he liked with his own.

The home nursery is a sort of epitome of the various grounds, and in it are situated the greenhouses, pits, &c., where the Azaleas, Ferns, &c., are mainly grown. The dwelling-house is just such as one might expect in a nursery of so many years standing—quaint and substantial, with none of the pretentiousness of modern “stuckupishness” about it, and having in front a fine bed of Conifers. I was at once struck with the quality of the *Araucarias*. I do not know whether there are two kinds of *A. imbricata* or not, but the thick massive character of the branches of those I saw here were very unlike that of many which I have seen in other places, where they exhibit a rather spindly appearance. Nothing could be finer than the character of these. Associated with them were various Conifers, of which there seems to be a nice stock. *Thuja aurea* in various sizes looked remarkably healthy, although the golden appearance, as it is well known, is not assumed until winter. However well coniferous plants may thrive in poor soil there can be no question that, like most others, they rejoice in a rich, deep alluvial soil, such as they have here, where, probably more liable to be cut off by frost, they flourish with great vigour.

Azaleas have not only found here a congenial home, as the many fine plants exhibited by the firm testify, but from hence have been sent out many of our most valuable varieties. When we mention such kinds as Barclayana, Criterion, Flower of the Day, Gem, Rosy Circle, Iveryana, Tricolor, and Variegata superba, not only every Azalea-grower knows them to be amongst the best of their class, but every frequenter of our great horticultural exhibitions knows them to be amongst the most attractive to general lovers of flowers. In my way to the houses where they are now safely quartered I noticed against the greenhouse a splendid plant of *Erythrina crista-galli* throwing up some magnificent spikes of bloom. It had evidently found a place well suited for it. The stem was of great thickness, and the flue passing behind it no doubt had contributed to this result. The stock of Azaleas is large and in excellent condition, entirely free from thrips and red spider, although it has required no little care to keep these under this season, and wherever watchfulness has been omitted they are sure to have made headway.

While writing on the subject of Azaleas I cannot forbear alluding to what is called the gravel-pit-house, as it struck

me that many persons might utilise some such place in their ground. It is really a large hole from whence gravel has been taken out, about 20 feet deep, and over it has been thrown a glass roof. The walls have been somewhat cut into shape; a platform has been placed in it; and here were several very fine large plants of Azaleas in full vigour. But its value consists in the fact that it is a complete protection against frost, and that Azaleas are kept here without a fire all the winter. When very severe weather sets in, as about two years ago, then a thick covering of leaves is thrown over the glass, and mats on them, and here the plants remained unharmed all through the severe frost: moreover, it enables Mr. Ivery to retard his plants, so as to have them in bloom for the later shows. It struck me that such a place would be admirable for growing some of the New Zealand Ferns in, and that a very pretty fernery might be thus made without much expense or trouble. In walking through the grounds, which contain a good general nursery stock, I noticed some fine standard plants of *Aithæa*, of which there are seven sorts, and a large plantation of *Dioscorea batatas*. Three rows of these were planted about 3 feet apart; a sort of arched trelliswork was made, and over it the foliage was running wild. The tubers are placed in ridges having a good depth of soil; and very large tubers, Mr. Ivery informed me, were thus produced.

It was from here, too, that the Buckland Sweetwater Grape was sent out, which has proved itself to be one of the very best White Grapes known, and is especially valuable for ripening in a coolinery. I believe that the fine Grape General Marmora is almost identical with it. Mr. Ivery has also a fine collection of the various Grapes grown.

But after all the charm to me in this nursery was the fine collection of British Ferns which have been so often admired at our exhibitions. Here were to be seen the fine plants which have so often done duty in London; and here also were myriads of young ones in various states of forwardness. The seeds were all sown in heat, and in pans there were multitudes of various kinds in a state of preparation.

Mr. Ivery informed me that, whatever seed they sow, they are sure first of all to get a crop of the common hardy Fern. This arises from the quantity of spores in the peat in which they are sown; and even when the proper varieties come up they have to be proved for some time before they can be sent out. The healthy appearance of the young plants evidenced the great care and attention that had been paid to them, and I shall be very much surprised if the cultivation of British Ferns does not become very popular. The varieties are almost endless and very beautiful; and although we do not find the gigantic tree Ferns, yet we have some noble-looking varieties, and in many of the new ones most exquisite and delicate forms.

I noticed as amongst the most beautiful the following:—Among the *Aspleniums*, *adiantum nigrum* and *acutum*, *fontanum*, and *septentrionale*. Of the many varieties of Lady-Fern (*Athyrium Filix-femina*), I noticed especially *apuaforme*, a curious-looking variety, the pinnae being much in the shape of little fishes; *corymbiferum*; *depauperatum*, with tasselled-looking appendages; *Fieldiæ*, very curious and beautiful; *Frizelliæ*, another remarkable and fine variety; *multifidum*; *plumosum*, very distinct; and *thyssanotum*; and a new variety, *micronatum*, to be sent out this autumn. *Hymenophyllum Wilsoni* is very beautiful; and extremely curious is the little *Cystopteris montana*. Amongst the Male-Ferns (*Lastrea Filix-mas*), I remarked some fine sorts:—*Bollandiæ*; *crispa*, very handsome; *cristata*, tasselled and very fine; *Schofieldiæ*, and *fureans*. Amongst the Polypodiums were *Robertianum*, *cambricum*, and *hibernicum*. *Polystichum* afforded some fine forms, such as *cristatum*, *plumosum*, *proliferum*, *Wollastoni* (most lovely), and *lonchitis*, or Scotch Fern. The *Scelopendrium*s were very numerous: amongst them *digitatum*, *endiviaefolium*, *macrosum*, *marginatum*, *sculpturatum* were excellent. *Woodsia hyperborea* is a pretty little thing. But all, or nearly all, had their peculiar beauties, and I could hardly determine which to select as most worthy of cultivation, but the above list contains some of the most desirable.

To any one desirous of commencing the growth of these beautiful forms, I do not think I can give better advice than to go down and see for themselves. The distance from London is not great. They are sure to meet with

every attention from Mr. Ivory or his intelligent foreman, Mr. Appleby, and I venture to say they will return highly pleased with their visit; and should they have more time than I had, there are Deepdene, Mrs. Hope's, and also Mrs. Cubitt's, which are well worth seeing. If they cannot do this they may very safely commit themselves to the care of Mr. Ivory. I for one hope to meet him with increased vigour at the shows next year, if not before, when I hope British Ferns will receive a little more consideration than they have heretofore done.—D., Deal.

STOPPING BLEEDING IN CONIFEROUS TREES.

A CEPHALONIAN Pine, a fine young tree 25 feet in height, was severely wounded three years ago. The blow caused a deep indent, which we filled up with a mixture of cowdung and clay; but this did not check the bleeding, and it still continues, so that the foliage is beginning to be affected. Can you tell me the right course to pursue for restoring the tree to health?—N. RYECROFT.

[A very likely way of stopping the bleeding of your Pine would be to remove all diseased appearances from the wound with a sharp knife. Then let it be seared with a hot iron, and apply a good coat of pitch while the place is dry. It requires desperate means sometimes to stop the sap in such cases, and what we prescribe is frequently effective, and is most likely to be so if applied during a season when the ground is dry, or when the sap is flowing at its minimum.]

GLADIOLUS REINE VICTORIA.

I THINK it a pity that the public should be misled by an erroneous statement made in No. 122, by your able correspondent, "D., Deal," with regard to the price of the Gladiolus Reine Victoria. I am in receipt of MM. Verdier's price for this variety, and find they intend sending it out at 6s. per root.

Few have hailed with greater pleasure the advent of this beautiful flower than myself, and I have most particularly observed, that where a blossom of such distinction as Reine Victoria has been introduced, the price invariably maintains its ground; and will you permit me to inform your correspondent, "D., Deal," from personal observation when visiting M. Ch. Verdier some short time since, that a thousand roots of Reine Victoria would prove to him an exceedingly limited stock, and very inadequate to meet his extensive English orders?—G. P. O.

AMARANTHUS MELANCHOLICUS RUBER CULTURE.

SOME time ago you requested that your readers would give you their experience with regard to *Amaranthus melancholicus*. I do not think that any have done so, so perhaps my experience, though on a very limited scale, may be acceptable.

From my own observation and from the testimony of others, I conclude that its seeds germinate very freely. I had a very small packet, and every seed came up. In its after-growth it is very tedious. I fear that it is not suited for the damp cold climate of Ireland, for I have not seen a plant in any of my neighbours' gardens exceeding 3 inches in height. My best plants are 9 inches high and 1 foot across. I sowed them in a brisk heat, and when they came to their second leaf I pricked them out. I lost more than a fortnight by putting them into altogether wrong compost—a rather stiff retentive loam, with dull heavy sand through it. They did not grow at all in this. I then pricked them out into a very light compost composed of loam, leaf mould, burnt earth, and pounded freestone, and placed them in a Cucumber-frame. Here they grew rapidly till the first week in June, when they were put out in their beds. During that month, which was wet and cold, they did not grow at all; but during July, which was unusually dry and warm, they have for the most part grown well. I must confess, however, that there has been great irregularity in their growth, some of them quite forcing ahead of others. I have them in beds with *Bijou Geranium*. Planted in alternate

rings, and with an edging of *Lobelia speciosa*, they are as beautiful beds as I ever saw, when the sun is in a proper position.

Here let me add—and I wonder I have never seen it noticed in THE JOURNAL OF HORTICULTURE—that it is highly important to choose a fitting position for this plant. Its whole beauty consists in being looked at between you and the sun; and it should be a little elevated, so that the sun may play well through its leaves, which are of a most exquisite ruby colour when thus seen—quite unapproached by any other plant that I am acquainted with. Looked at from above, with the sun beating down on its leaves, it is simply a good dark leaf. I was not aware of this, and my beds are very badly placed. They can only be seen to advantage when the sun is setting; but at that hour I often stand quite entranced with their beauty. I am sure it would be a beautiful object in a hanging-basket in a greenhouse.—Q. Q.

MACLEANIA CORDATA (HEART-SHAPED-LEAVED MACLEANIA).

Nat. ord., *Vacciniaceae*. Linn., *Decandria Monogynia*. Sm., *Gaultheria cordata*, of Belgian gardens.—A fine greenhouse evergreen shrub, growing 3 to 4 feet high, with upright smooth branches. The leaves are opposite, oblong-lanceolate, entire, about 3 inches long. The flowers grow

in a second manner towards the extremities of the branches, three or four from the axil of each leaf; the corolla consists of an angular tube an inch long, bright red, with a yellow limb of five small, ovate, spreading segments, greenish before expansion.—From Chili: elevated regions in a calcareous stony soil; introduced to Belgium in 1843. Flowers in summer.—(*Gardeners' Magazine of Botany*.)

MELONS.—Will any of your numerous readers tell me if they have grown Melons in pots larger than I now have here in my pinery—viz., 5½ lbs., and their mode of doing it? and oblige a constant subscriber.—J. Z.

LARGE GROWTH OF POTATOES AND LETTUCE.

I HAVE just dug up some Potatoes (they are a pink sort, imported from Belgium last year), and I find a great number of the tubers sprouting, some with sprouts $2\frac{1}{2}$ inches long. Is this common? I imported also this year four bushels of White Belgian Potatoes, some of which I have dug up to-day. The haulm is something wonderful—over 6 feet in height, and the produce of seven plants 8 lbs. $\frac{1}{2}$ oz. My Belgian Pinks last year averaged, when dug up about this time, 8 lbs. to five plants or roots, and this on a clay soil. The Potatoes, however, were planted in soot and ashes, and earthed-up entirely with ashes.

I have cut Lettuces in my garden this year, seed imported from Brussels, of the following sizes and weights:—One 36 inches round, 2 lbs. $\frac{1}{2}$ ozs.; one 54 inches round, not cut; one 40 inches round, 2 lbs. 2 ozs.; one 52 inches round, not cut; one 42 inches round, not cut.—K. O. T.

[We commend this to the notice of our gardening friends, and shall be glad to have their opinion on the matter. Mr. Robson, to whom we forwarded the letter, says the produce of the Potatoes is remarkably good; but he expects they had plenty of room.

The dry weather, however, has so reduced the size and quality of the Lettuce on hand, that not having weighed any recently we cannot form so good an opinion on them; but yours are unquestionably good.—ERS. J. OF H.]

SULPHURED WATER AS A REMEDY FOR VINE MILDEW.

IT may be useful to some of the readers of your Journal to detail the means which I have found to answer in the prevention of this mildew. I have practised it for eight or ten years, and have not seen anything like mildew. I think it is also very useful to prevent other kinds of enemies attacking the Vine, as I see my Vine leaves look more healthy than those of some I have seen. There are two cases which I will mention: A friend of mine had to grow flowers all the summer in what he called one of his vineries. I went to see him about the middle of July before the Grapes began to colour. The berries were very good, but every bunch completely covered with mildew. I told him to buy 2 lbs. of black sulphur, and have two water-cans that would hold about three gallons each, to put 1 lb. of sulphur in each can, to add one gallon of boiling water to each pound of sulphur, and let it stand for an hour or two. Next, filling the cans with cold water, he was to let it stand for about twelve hours, and then pour the water off into other cans without any of the sulphur with it, or as little as possible. I told him to shut up the house early in the afternoon, and syringe well with this sulphured water, so that the bunches were well washed all over, then to fill the cans with sulphur in them, with water again, and to use it in the same manner, having the same sulphur, for three successive days. I called on my friend a few weeks afterwards, to see how the Grapes were looking, and was very pleased to see that the mildew had disappeared, and the berries were colouring and swelling well, and he had a very good crop, but of course they were not so fine as if the remedy had been applied sooner. I should state that he took all the pot plants out that were in full flower while he syringed the Vines.

The following year a gentleman wished me to look at his vinery. It was not so bad a case of mildew as the other, but the same remedy was used, and with the same good success.

Now, I treat my Vines the same, except that I use 1 lb. of sulphur instead of 2 lbs. to the same quantity of water, and I always apply the sulphured water when the Grapes are about the size of peas, and I have never been troubled with the mildew since I have done so. I think this is much better than seeing a quantity of sulphur on the Grapes, or all over the border or pipes. It would puzzle any one to detect the remedy when this sulphured water is used.

There is one thing I should like to find a remedy for, and, perhaps, some of the readers of your Journal could give me some information. I have had two large lights of Melons

looking exceedingly well and promising. A few days ago I gave them air as usual; all was right then, and the plants looked as healthy and as promising as they had done before. In the afternoon when I went to shut them up I found under one light the plant with its leaves all drooping down, not one leaf in its healthy state, and a day or two afterwards the other light went in the same way. The plants had Melons on about the size of a large apple, and since that time my Cucumbers have gone off in a similar way. How can this be accounted for?—J. K. (A CONSTANT READER).

[It is worth trying if this sulphured water will act as a preventive or cure of mildew. It is believed by many, judging from practice and not from science, that sulphur does impregnate water in which it is kept, though chemists say it is insoluble. Everybody knows that to prevent the mangle a roll of sulphur is put into the water which dogs drink. As to our correspondent's Melon and Cucumber plants, if he examines their roots we think he will find them decayed.]

ROYAL HORTICULTURAL SOCIETY.

AUGUST 4, 1863.

FLORAL COMMITTEE.—On this occasion the entries of subjects for examination were numerous. Messrs. F. & A. Smith, Dulwich, sent a very fine collection of their superb Balsams, for which a special certificate was awarded; *Brassica variegata*, and a seedling *Pelargonium* not in condition for judgment.

Mr. C. J. Perry had two seedling Dahlias, one of which, *Alexandra*, a light creamy ground faintly shaded with purple, of fine form and great delicacy, was awarded a second-class certificate. There is no doubt, should this flower be shown again, it will attain a higher position. The other seedling was a dark maroon of no particular merit.

Mr. Elkington, Bucks, showed two seedling Picotees of promising qualities. Exhibition, a heavy-edged flower, with remarkably pure white ground, was commended; Duke of Buckingham, a heavy purple-edged, will probably be again exhibited. The flower was small but distinct.

Mr. Bull exhibited three Ferns—*Hymenostachys elegans*, a small Fern with pellucid fronds in the form of *Blechnum*, with spear-shaped fertile fronds, first-class certificate; *Hymenophyllum crispatum* and *H. flexuosum*, two plants of no particular recommendation.

Mr. Chater's seedling Hollyhocks were exceedingly fine. *Cherub*, a rosy salmon, fine, full flower, medium size—first-class certificate. Mr. Chater also exhibited eight other seedlings of fine quality, but not sufficiently distinct from well-known good varieties. Among them we noticed Rev. H. H. Dombain, a dingy yellow, with the base of the florets shaded with rose; Rev. J. Dix, bright ruby red, a loose flower; Princess Alice, a bright rosy pink.

Messrs. Downie, Laird, & Laing, sent four very fine seedling Hollyhocks, one named R. B. Ullet, a bright light red, very full and well-formed flower—first-class certificate; Mrs. Binning, a deep rosy pink, fine-formed flower, medium size, distinct—first-class certificate; Magnificent, very similar in colour to R. B. Ullet, with a broad guard leaf—a very noble flower; Countess of Craven, delicate rose, full flower, and distinct; Carus, a deep purplish-rose. Messrs. Downie, Laird, and Laing, also sent a collection of single flowers of Hollyhocks, which received a special certificate. We must here remark that it would be both to the interest of the exhibitor as well as of advantage to the flower if seedling Hollyhocks were brought before the Committee in spikes instead of three single blooms. It must be evident to all florists that this is the only legitimate way of judging the seedling Hollyhocks.

Mr. E. P. Francis, Hertford, exhibited his dwarf scarlet *Pelargonium*, Mrs. Cowper, which was commended at the July Great Show, and from maintaining its good character was now awarded a second-class certificate. This variety much resembles Waltham Pet, but is not so bright in colour, although the flowers are not of so good form.

Mr. G. Smith, of Hornsey, sent a distinct and good variegated sport from Stella. The variegation is clear and distinct, the flowers as brilliant as Stella. This will form an attractive bedding plant. It was commended. He also had a

seedling Fuchsia, of a drooping habit, but of no other merit.

Mr. Veitch again exhibited *Mntisia decurrens*, a handsome hardy climbing plant, which had received a first-class certificate on a former occasion; also two plants of *Canna nigricans*, a dark-foliaged variety.

Mr. Keynes, Salisbury, brought three seedling Dahlias, John Wyatt, a bright purple or puce flower, distinct, and of very promising qualities. A second-class certificate was awarded. This flower will, doubtless, when shown again, obtain a higher award. The other seedlings were of no particular merit, and much resembled named varieties in cultivation.

Mr. Toogood, Westergate, sent a bright scarlet, highly-scented Clove Carnation, a very useful border plant, as a companion to the old red and white Cloves; Mr. Dobree, Wellington, cut flowers of four seedling Verbenas, which had faded in their journey; Mr. George Jackman, Woking, two very showy and beautiful seedling Clematises, hybrids between *lanuginosa* and *Hendersonii*—*C. Jackmanii*, a beautiful broad-petalled, violet flower; *C. rubro-vioacea*, a finely-formed, reddish-violet-coloured flower, very distinct. Both these varieties will prove a great acquisition to our list of hardy climbers.

Mr. Whiting, Deepdene, again sent some pleasing varieties of *Calendula officinalis*, varying in colour from deep orange to bright primrose; some of the flowers shaded or mottled with each of these colours, perfect in form, much resembling a depressed *Ranunculus*.

Mr. Eyles placed three fine plants of the noble terrestrial Orchid, *Disa grandiflora superba* on the table. These plants had been grown at the Society's gardens at Chiswick in a cool frame, and were specimens of good cultivation.

FRUIT COMMITTEE.—Mr. Rivers in the chair. Numerous prizes were offered at this meeting, but the only classes in which there were any entries were Apricots and Melons. In the former Mr. Cox, of Redleaf, exhibited very fine specimens of the Moorpark and a dish of Kaisha. The latter was the only one that could compete as one of the newer varieties, and it was awarded a second prize, because the fruit were not first-rate examples of that variety. In Melons there were three competitors. Mr. Whiting, of the Deepdene, exhibited Pottle's Hybrid Green-flesh, which was not thoroughly ripe, but is evidently an excellent variety. Mr. Turner, of Slough, sent a variety called Hybrid Green-flesh, which, however, proved to be a white-flesh, and not in good condition. Mr. Crawshay, of Cyfarthfa Castle, sent a Rock Cantaloup Scarlet-flesh, which was also unripe. As the conditions expressly stated that all fruit must be ripe and fit for table, the prizes were not awarded.

A seedling Grape was sent from Mr. Samuel James, gardener to Lord Dartmouth, Patsball, Albrighton, near Wolverhampton. It was raised from seed of Black Morocco fertilised with Black Frontignan. The bunch is very small, and thinly set; the berries are small, round, black, and covered with a fine blue bloom. The skin is very thick and tough, and the little flesh there adheres very closely to it; the flavour is brisk and good. Judging from the specimens of the fruit exhibited the Committee did not consider it possessed any merit.

Mr. Rivers, of Sawbridgeworth, exhibited fruit of his Victoria Nectarine, which were fine large specimens of that valuable novelty, but unfortunately they were overripe, and did not convey an idea of the true flavour. The same may be said of Victoria Peach, also an excellent sort, which Mr. Rivers has found to be much earlier than Early York. Two new Cherries were also exhibited—Rival, a Black Heart Cherry of good size, heart-shaped and uneven in its outline, which has the valuable property of hanging till September. Belle de Rocmont is a large black Cherry of the Black Heart race, which will be highly valuable as a late Cherry. Neither of these was as yet perfectly ripe, and gave every appearance of hanging for six weeks to come. Mr. Rivers also exhibited excellent specimens of Dove Bank Plum, a large, purple, round variety, grown in Derbyshire, and which is frequently confounded with Goliath. It has quite a rich flavour. The Early Mirabelle is a small yellow Plum in the way of *Jaune Hative*, and excellent for compotes.

Mr. Whiting exhibited fruit of a rare variety of Peach called Early Purple. It is not the sort that is generally

known by that name, and which is a form of *Grosse Mig-nonne*; but a small Peach, the flesh of which has a tendency to adhere to the stone. The flowers are large, and the leaves have kidney-shaped glands. It is the Early Purple of Hogg's "Fruit Manual," and the *Pourprée hative à grandes fleurs* of the French.

Mr. Rivers sent samples of the Royal Ash-leaved Kidney Potato, a most prolific variety, producing very large and handsome tubers.

THE PROPOSED GARDENER'S FRIENDLY SOCIETY.

It is difficult to account for the apathy and indifference with which the proposal for the formation of the above Society has been received by the profession, more especially as the benefits to accrue to each individual are so apparent as to require no argument to demonstrate. So far, however, it seems to have been received with a greater amount of indifference than one would have thought could possibly have existed in a matter that so nearly concerns ourselves. This is much to be regretted, inasmuch as it betrays a want of unanimity and co-operation amongst gardeners generally. It is equally clear that some such Society, through which, by the expenditure of a comparatively trifling sum, a gardener can secure for himself support in sickness and in old age, is really wanted.

Thanks are also due to the respected Editors of this Journal for the interest they have taken in the matter. They supported the scheme from the first, lent their aid by promulgating a set of rules likely to meet the requirements of the case, and opened the pages of the Journal to a free discussion of the subject.

Gardeners are numerous enough and powerful enough to establish a Society of their own, and one is truly astonished that the matter was not taken up as soon as propounded and acted upon with vigour. All that is wanted is a start; the Society once fairly put upon its legs, its success is certain. The "stir-'em-up" papers that have recently appeared in the pages of the Journal from the pens of Messrs. Chitty, Earley, and others will, I hope, have the effect of rousing up the lethargic amongst us into life and activity. I may add, in conclusion, that I shall be happy to have my name added to the list of subscribers.—J. DUNN, *Horrocks Hall Gardens, Wigan.*

On behalf of myself and many gardening friends, I thank, you for your great kindness in opening the columns of your valuable Journal for discussion on this subject, and giving us the outlines of a Society. The original question seems to me departed from, and a Benefit Society substituted, which I am sorry for, as, although a Gardener's Benefit Society is very much wanted, I think a Gardener's Examination Society is wanted still more. Why are nearly all our great professional men silent? Surely it is not because they have been somewhat more fortunate than some of us, and do not want it personally.

As regards your very able and, I will say, good programme of a new Society, with its well digested scale of subscriptions for sickness and old age, living as I do in Hampshire, I know it is good in the working. But, as I opine, a great many gardeners, like myself, are now in some sort of Benefit Society—viz., Oldfellows, Foresters, &c., and having perhaps a family to bring up, could not afford to enter such a Society as you propose; but were there a separate subscription for an annuity at sixty or seventy years of age, without the sick pay, myself and I believe a great many others would join both at reduced subscriptions for the sake of future benefit, and help to form a very-much-wanted Society; still I do hope something of "G. A.'s" proposition will be added to it.—J. A. HUNTS.

In our proposed rules of a Gardener's Benefit Society any gardener could subscribe to the annuity fund perfectly irrespective of the sick fund.—EBS. J. or H.]

THE question of a Gardeners' Society has, of late, been frequently mooted in the pages of THE JOURNAL OF HORTICULTURE. Rules and suggestions have been given; but to assume a practical form it will be necessary to hold a public

meeting in the metropolis, where all gardeners of the neighbourhood, who feel an interest in the subjects to be discussed, could attend. It is only by such means that a code of rules could be drawn up, a President, Vice-President, and Committee, &c. appointed to meet general approbation. Public branch meetings in unison with the metropolitan would then take place.

The great object is to arrange the rules and appointments to office in a manner to obtain public confidence. Now that the evenings are approaching when gardeners will have more leisure, I hope that the Editors of THE JOURNAL OF HORTICULTURE will not allow the subject to drop until it is tested by public meetings.—W. KEANE, Kensington.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CALCEOLARIA PUNCTATA (Dotted Calceolaria).—*Nat. ord.*, Scrophulariaceæ. *Linn.*, Diandra Monogynia. "A very ornamental species, native of the southern provinces of Chili. Introduced by Mr. Richard Pearce, the well-known and most successful collector of Messrs. Veitch." Flowers pale lilac.—(*Botanical Magazine*, t. 5392.)

CRASSULA ROSULARIS (Spreading-leaved Crassula).—*Nat. ord.*, Crassulaceæ. *Linn.*, Pentandria Pentagynia. Native of Natal and other parts of South Africa. Flowers yellowish-white.—(*Ibid.*, t. 5393.)

ANCHOMANES HOOKERI var. *PALLIDA* (Hooker's Pale Anchomanes).—*Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria. Native of Fernando Po.—(*Ibid.*, t. 5394.)

LEWISIA REDIVIVA (Spat'um, or reviving *Lewisia*).—*Nat. ord.*, Portulacææ. *Linn.*, Polyandria Monogynia. This is the "Spat'um" of the North American Indians. It is called "rediviva" on account of the root, though long dried, reviving when planted. Sir W. Hooker had it two years in his herbarium, and it then produced a crop of leaves. Native of California. Flowers pink and blooming in May.—(*Ibid.*, t. 5395.)

SENECIO PYRAMIDATUS (Pyramidal Groundsel).—*Nat. ord.*, Compositæ. *Linn.*, Syngenesia superflua. One of the most ornamental of the genus, which includes about six hundred species! It is a native of South Africa. Flowers yellow, blooming in June.—(*Ibid.*, t. 5396.)

OPHELIA UMBELLATA (Umbelled Ophelia).—*Nat. ord.*, Gentianaceæ. *Linn.*, Pentandria Digynia. Native of the Nilgherry Hills. Flowers bluish-white, blooming in June.—(*Ibid.*, t. 5397.)

MIMULUSES.—*Mary*, bright yellow, blotched with crimson. *Rosa*, crimson, edged with golden yellow. *Bessie*, scarlet-crimson, edged with golden yellow; lip yellow, with irregular band of crimson.—(*Floral Magazine*, pl. 157.)

AZALEA, *Louise Van Baden*.—Of Belgian origin. Stouter-petaled than any other white Azalea.—(*Ibid.*, pl. 158.)

AMARYLLIS, *Regina spectabilis*.—Scarlet, striped with crimson, and a white band down the centre of each petal.—(*Ibid.*, pl. 159.)

RANUNCULUSES.—*Fidelia*, creamy ground colour, with rosy carmine edge. *Linden*, straw-coloured ground, centre of each petal spotted with bright rose.—(*Ibid.*, pl. 160.)

DISA GRANDIFLORA SUPERBA.—Raised by Mr. Leach, the first successful cultivator of the species, than which this variety is longer-flowered and brighter-coloured.—(*Florist and Pomologist*, ii., 105.)

PEAR, *Zéphirin Grégoire*.—Raised by M. Grégoire of Joazeiro. "A most delicious Pear, and, like Joséphine de Malines, is always good. It comes into use in December and lasts till February." Pale yellow, cinnamon-dotted when ripe; shape pyriform.—(*Ibid.*, 112.)

LARGE ELM.—Mr. Robson's article on deciduous trees induces me to send you the dimensions of a gigantic Elm which grew on my glebe, and was blown down by the autumnal gales of 1858. The girth at 4 feet from the ground was 23 feet 4 inches, and at 1 foot from the ground, 25 feet 10 inches. It fell obliquely across the turnpike road, blocking it up completely, and damaging considerably a Laurel-hedge and Horse-Chestnut tree in my garden. Its

height was between 70 and 80 feet. Some of the limbs were sound, but the trunk was a mere hollow shell.—ROBERT C. DOUGLAS, *Stoke Lacy Rectory, Bromyard.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

OWING, probably, to the dryness of the season, I find it is a general complaint that portions of the Brassica tribe have gone off blind, or, as some call it, false-hearted. This must be looked to in time, and all vacancies filled up, as far as practicable, with strong plants from the nursery-beds, lifting them, if possible, with good balls of earth, and giving every encouragement in the way of judicious watering. *Broccoli*, we will suppose that all the spring and midwinter sorts have been planted some time, and that Turnips for October and November are in also; still it remains to insure a continuous succession of Cauliflowers and autumn *Broccoli*, also a full supply of salads. The Cape *Broccoli*, although apt to sport, are amongst the most useful for the certain supply of the house. Towards the end of the week the principal spring crop of Cauliflower and Walcheren *Broccoli* should be sown. Sow thin in an open place, and not on too rich soil, or the plants will become gross and less liable to stand through the winter. *Cabbage*, another sowing may be made in the end of the week to stand in the seed-bed through the winter; a late-sowing sometimes comes in very useful. Also make a sowing of Red Dutch for summer use. *Celery*, previous to earthing-up the first time, give the trenches a thorough watering, as the plants will not receive much benefit from its application afterwards. The earthing-up to be carefully done, the whole of the leaves being kept close together at the time. *Dwarf Kidney Beans*, keep the crop closely gathered, for if allowed to remain till they are too old for use they discontinue to bear as they otherwise would do. *Lettuce*, sow largely for standing through the winter. The Brown Cos, Black-seeded Cos, Green Cos, and Hardy Hammersmith or Brown Dutch are the best sorts for sowing at this season. Plant-out from the late sowings for autumn use. *Onions*, pull-up and house those that have done growing. It is a good time to sow for spring use; the Welsh is hardy, but the Deptford will stand well; and the merits of the Silver-skinned, as a winter Onion, are becoming more generally known. In regard to prescribed periods of sowing crops, in general it is advisable to study both the soil and locality of a garden that its advantages and inconveniences may be understood; there are localities where it is necessary to deviate considerably from ordinary practice to meet their peculiarities. *Parsley*, thin-out and cut-down a portion of the spring-sown that a fresh growth may be made before winter, a part of the thinnings may be potted in 12-inch pots for removing to frames in the winter. *Radishes*, sow succession crops of the White and Red Turnip. *Spinach*, trench, manure, and dig a piece of well-drained ground for the winter crop. From the 12th to the 15th of this month is a favourite time for sowing it. *Tomatoes*, expose fully to the sun the most forward of the fruit; remove some of the leaves which shade it; keep all the shoots stopped as soon as there is sufficient young fruit on the plant. As the rains are very partial, it is still necessary in many localities to continue watering seed-beds and recently-transplanted crops. Keep the soil loose where practicable. Give timely thinnings to those crops that require it, and water afterwards if the soil is dry.

FLOWER GARDEN.

We beg to repeat that this year's beauty should assist to suggest next year's improvements in the distribution of the masses in the flower garden. Attention should be given to effect, duration of bloom, habit, and colour of the different plants, and another arrangement planned for a future season. Hollyhocks, Dahlias, and tall herbaceous plants to be made safe from the effects of high winds by securely fastening them to their supports. The like attention to be paid to climbing plants against walls and trellises, standard Roses, &c. Mark the best Hollyhocks for seed. We are glad to see that this magnificent flower is becoming a public favourite. The general pruning of evergreen shrubs to take place, reducing straggling growths within proper limits, but avoid giving them anything of a formal character, the object is to assist,

not deform Nature. Cuttings of choice herbaceous plants put in early should be pricked-out or potted immediately they are struck to get well established. Early-struck Pinks and Pansies may be planted-out for autumn blooming. Young seedling Wallflowers, Brompton Stocks, Sweet Williams, and other biennials to be either planted out into reserve-beds or where they are to flower. Divide and repot Auriculas and Polyanthus, so that the young and old plants may be established before winter. Gravel walks to be frequently rolled during heavy rains to keep them firm.

FRUIT GARDEN.

The preservation of wall fruit from birds and insects should occupy attention. The bean-stalk earwig traps to be frequently examined. Worsted or other small mesh netting may be employed. Look carefully over Peach, Nectarine, and other fruit trees, and remove nails or shreds that interfere with the swelling fruit. In stopping and arranging the wood let only as much as can conveniently be laid-in be allowed to remain, and that convenience qualified by due considerations for the perfection of the fruit and the proper ripening of the wood, which only the influences of sun and air can accomplish. Pear shoots which have been left or only partially shortened to be now pruned back to three or four eyes. The value of the Strawberry as a summer fruit renders its successful cultivation a matter of some importance, the more especially as it comes within the reach of the humblest possessors of a garden. The present is the best season for making new beds. Strawberries thrive best in a deep rich loam and open situation; the land should have been previously trenched 2 feet deep, and well manured, for Strawberry roots penetrate to a great depth. Select runners which have either been laid into small pots for the purpose, or the strongest which have taken root from the older beds. Water them during dry weather until they are well established.

GREENHOUSE AND CONSERVATORY.

Early provision should now be made for carrying out a late display by means of young stock in succession of those flowers which will withstand the gloom of autumn. Late Fuchsias, Achimenes, Scarlet and other Pelargoniums, Plox Drummondii, Verbenas, Ageratums, Salvias, &c., in pots will, although not rare, greatly assist in keeping up gaiety to a late period. Carefully tie-out the different varieties of Lilium lancifolium before they come into flower. Finish the potting of Chrysanthemums, and stake them securely as they advance.

PITS AND FRAMES.

Make all necessary preparations here for propagating plants for next year's decoration of the flower garden. Make a full sowing of Schizanthus Hookeri and S. pinnatus for flowering next spring; also sow Ten-week and Intermediate Stocks for the same purpose. See that all structures are in good repair; all lights that require it to be glazed and painted, and the interior of the pits smartened-up by applying the whitewash-brush.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Dug down a quarter of Strawberries, trenching it two spits deep, stirring the bottom with a pickaxe, and turning in all the Strawberry plants, litter, &c., into the bottom of the trench. Never before tinned-up garden ground in such a dry hard state. The Strawberry plants had stood three years, and borne immensely, but so dry and hard had the ground become, even though the surface was well littered to keep the fruit clean, that a pick had to be used to help the spade. The weather being dull and drizzly, planted the ground as finished with Cauliflower, Broccoli, &c., lifting with balls the plants that had previously been pricked out, and planting them in trenches with the spade, and watering them as we planted them, turning the dry earth on the surface. As our last resource, broke into a deep well of house sewage, which though too strong for many things, has just been the thing for Cauliflowers and Peas. Lost some scores of heads of Cauliflower, the heads coming too soon and loose for want of water. Some of our finest rows of Conqueror Peas gave up flowering and bearing prematurely from the same cause. We were in a complete

fix if we obtained water for vegetables and flower-beds, there was the more than likelihood that cattle would die from thirst, and you may judge of the pleasure experienced in the showers of Wednesday, windy though it was. Some splendid long rows of Calceolarias had been watered the day before from the sewage-well, as they would have died if left longer without moisture, and one good thing is, we shall have a pump to this sewage-well, and as we are so short of solid manure we will make it the means of producing fine vegetables. The scent is not suited for the flower garden, though we gave a good soaking to splendid Hollyhocks that were losing their large lower leaves from drought. The scent without any firing soon goes off in a kitchen garden, and if people are squeamish, a little dry earth thrown over makes all as sweet as a nut. With the exception of a small reserve of clear rain water in a tank for plants in pots, and syringing, but for this old sewage-well that had not been looked at for twenty years we were entirely without liquid. What we had was drawn up in pails with ropes, but once we have the pump we shall feel more independent, having frequently proved the value of such watering for kitchen-garden purposes.

In all vegetable matters proceeded much the same as previous weeks; find that next to Cauliflower, Lettuces of a large size stood worst, but there are plenty of successions. Planted out more, and a nice stock of Endive of the first, and a little of the second sowing. Earthed-up Mushroom-bed, having previously cased it with some burrowloads of sheep-dung packed off the roads in the park. We believe that a shallow bed cased with dried sheep-dung would produce abundance of Mushrooms without any spawning at all, though, of course, it is best to be sure. So far as our experience goes, the best plan for making all right with the superintendent of the kitchen, is never to be without plenty of Mushrooms, Onions, and Parsley. As respects other vegetables, there is nothing like having plenty for an easy life; but one great secret we will let out for the benefit of our young brethren—and that is, if you are scarce of anything, never let it be known. We do not mean to insinuate that there is anything of mere contrivance about it. We base our advice on the simple principle, that we generally value most and think most about what is scarce. When we are at all short of Cauliflower, Peas, Beans, &c., it is best every way to say nothing at all about it, if you can help it. If you do, you may depend upon it that that identical article will be most in demand. The work in general has been of a routine character.

FRUIT GARDEN.

In cold nights put a little fire in the vineries, and fresh-surfaced the pipes with sulphur. Gave a little water also to the borders out-side. Exposed the wood of the earliest small Vine-pit of three lights—the next five are not quite finished. In very hot days sprinkled the shelves and floor of the vineries to prevent the air being too parching. Leave on air still at night at the top of the house. To avoid drying have given little front air this season, and we do not see that the Vines seem to care about it. In fact, in all lean-to houses we look on top air as the great source of safety. In hot days these houses were frequently above 90°, at night they would generally fall to about 55° or 60°. Engined with water Peach-house from which the lights had been removed to be painted, as red spider had made its appearance. Find some of the fruit of orchard-house marked by the brown beetle before we succeeded in getting rid of it; but on the whole we have some excellent fruit and plenty coming, though we must part with some very old trees that were in a bad state before the house was made over them. They produced very heavily last year, and the fly was difficult to dislodge this season, though even now they have a fair crop; still we should hardly like to trust them, though making fair wood. This black beetle seems to have less power to injure Nectarines. These are now fine, whilst some Peaches beside them seem to have little warts, as if the epidermis had been bitten. However, they will come in well for tarts, cream, and food dishes of dessert. Went over Peaches and Apricots on ladders, moving leaves that shaded the fruit, and giving the fruit thinning to Nectarines, &c., that were too thick. Went to Flies and netted Gooseberries, Morello Cherries, and Late Strawberries, and as soon as possible will thin Peas on dwarf, which are very thick—too thick to ripen

NAME OF GRASS (E. T. A.).—It is not a Grass, but one of the Spergulars. We cannot decide which species it is unless we see the flowers.

FIGS FALLING (*E. S., West Wickham*).—On your gravelly soil there is a deficiency of moisture, probably at the roots of the trees. Raise a low bank, at about 3 feet from the stem, round each tree, and pour into it a bucket of water. Then put on some mulch and repeat the watering twice weekly, whilst dry weather continues.

VARIEGATED ARABIS PROPAGATION (*M. F.*).—As rooted offsets are not furnished very abundantly, we generally put in a good batch of slips any time during showery weather in the summer. We sometimes put them in as early as March, and at others as late as November, the plant being so accommodating as to strike well at all times. Of course cuttings put in late generally remain in their place until spring. We yearly raise a good quantity from spring or early summer cuttings to plant in the beds that Geraniums, &c., have been removed from in autumn. Any common sandy soil will do to strike them in, shading them for a time in sunny weather.

PEACHES NEARLY RIPE FALLING (*A. Z.*).—The trees are probably deficient in moisture at the roots. Treat them as we have told another correspondent to treat his Fig trees. What you term "rotting" in your Grapes is probably "the spot." The roots of the Vines should have some rich compost applied to them, and be liberally watered with tepid water. More air also should be given by day and night. Strawberries becoming mouldy to the forcing-house intimates that the air was kept too moist and stagnant. It certainly was not caused by "too much drainage."

GOLDEN-LEAVED GERANIUM (*An Amateur*).—There is a marked difference in the flowers of Cloth of Gold and Golden Chain, the former being a good scarlet almost equal to Geranium Tom Thumb, the latter a dulled red, and not so good a shape; the foliage is much alike. We may, however, say that amongst the various kinds of this class that we grow, we like Golden Circle best, as it is a free-grower and is only a shade less yellow than the best of them. We have upwards of one hundred plants of each of the following kinds:—Golden Chain, Golden Fleece, Golden Ivy-leaf, Golden Circle, Golden Vase, and Cloth of Gold; and in smaller quantities Gold-leaf, Miss Pollock, and some others. Not any of them comes up to our notion of what is wanted of a gold-edged Geranium; but we may be fastidious. In many instances the summer growth is so exceedingly small that propagation is a slow affair, excepting under glass in the winter and spring months. Further articles on variegated Geraniums will be forthcoming shortly, and perhaps other kinds noticed.

NAMES OF PLANTS (*W. W. Wilson*).—1, the Purple Vine Bower, Clematis viticella purpurea; 2, Sophora japonica pendula, a free and fast-growing tree; 3, Gleichenia triacanthos, the Honey Locust Tree; 4, Catalpa bignonioides, common Catalpa, or sometimes called Tignonias catalpa; 5, Datura stramonium, common Thorn Apple. (*An Old Subscriber*).—The large leaf is from Cissus discolor; the jointed leaf is from Phyllanthron comorensis (Bojer), a native of the Comoro Islands, from which it must have been introduced to Brazil, whence you say you had it, probably either through Kew Gardens or by Mr. Durcan, Director of the Mauritius Botanic Garden, who exchanges plants with a Brazilian correspondent. (*G. C.*).—It is a Lobelia, but not to be named from a small spray quite dry. (*E. J., Spring Bank*).—Hordeum jubatum, or Long-bearded Barley Grass. A hardy biennial; native of North America. (*G. Sum*).—Gnaphalium lanatum, so much employed now as an edging plant. (*J. R. R., Hoxton*).—1, Drosera rotundifolia; 2, Erica tetralix; 3, Sphagnum, or the grey Bog Moss, the peach-coloured variety of Sphagnum palustre of Withering.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

SELECTING BIRDS FOR EXHIBITION.

It is important that those who intend to be competitors for the great events of the poultry-yard, should now make selection of the birds on which their success may depend. There is, perhaps, no time of the year when this can be done as easily as at present. The evidences of growth and frame are unmistakable, and faults are equally developed. It has always been our opinion that those intended for Birmingham should there make their *début*. Admitting that they are perfect in size, shape, and condition, they have nothing to spare—all is required for success in that great contest. If that be true, nothing that is faulty can hope: no bad comb, faulty claw, or deformity can be tolerated. It is particularly at this season of the year, when the weather is hot, when meat does not relish, and when vegetables are good, young, and cooling, that poultry is most in request. It is now that the broods are scanned with an eye that threatens death to many an inhabitant of the yard. While a proper selection will certainly swell the profit column at the end of the year, so an improper one will assuredly put profit out of the question. When two large, white, succulent Dorkings appear on the table, they are not the less relished because the pullet was four-clawed on one foot, and the cock was decidedly weak on his legs. When two pretty Hamburg chickens, round, short, and full-breasted are being admired, no one will know they were both single-combed. It is the same with all. Every advantage of food and run should be given to those that are intended for stock or exhibition; and it is well, if it can be done, that all faulty chickens intended for the table should be withdrawn from the yard, and put in a place apart. Dorkings will, some of them, come with hideous legs, long thin claws going up all one side of the leg; others sin in an opposite direction and fail in the number—they have

four instead of five. Some appear of such colours that, although we are latitudinarians in that particular, we cannot advise them to be saved. Hamburgs will sometimes sport single combs and five claws. Spanish, instead of being long, thin, greyhound-looking fowls, will come dumpy, and squat-formed pullets. Indeed, every breed at times sends forth its defects.

Where eggs only are required, it stands to reason faulty birds will lay as well as perfect ones; but care must be taken none such are put under hens to produce chickens, as experience proves defects are more certain of transmission to offspring than virtues are. This is another reason why we advocate the separation of the table and faulty birds from the perfect ones—there is no possibility of a mistake in the eggs of either. It may appear of little import now, but it is possible, arrangements may be making at this time that are to last through the winter; and it would be more than tiresome to find the eggs set to produce chickens in January, to be the unmistakeable produce of the pariahs. If it can be conveniently done, it is advisable in both instances to keep the sexes separate. Early maturity is desirable neither for the table nor for exhibition. In the first instance it hardens the flesh, in the second it stops growth. Chickens grow and ripen slowly in the winter; and even if they are one month too old for the table of a gourmand, yet at that time of the year, if they are killed when quite empty of food and water, they may be kept till they are tender, and they will be full of flavour. As this is intended for those who eat poultry, we will endeavour to leave nothing unsaid on that part of the subject. Although fowls that have arrived at "a certain age" may be kept till they are tolerably tender, it is not desirable to keep them till they attain that age. Care should, therefore, be taken to kill-off the oldest brood first, and not to take up the first two or three that come to hand. Often one is killed twelve weeks old and put with another that is sixteen. If the sixteen-weeks brood is killed first, there is a month before those at twelve in which they will improve daily. The observance of these trifling rules will make the poultry-yard of the cottage or the "*ferme ornée*" what it should be—a valuable adjunct to the table and larder, and a self-supporting and amusing hobby.

SPANISH FOWLS FOR A SMALL ENCLOSURE.

Will you tell me the number of fowls (Spanish) I can healthily keep in a yard 25 feet square; also the best way of building at its end a fowl-house 25 feet by 6?—A COUNTRY POULTRY-FANCIER.

[You can easily keep ten or twelve Spanish fowls in a yard 25 feet square. They are not fowls that require much liberty, although, when they have it, they enjoy it to the full. That number would not want a house as large as you propose to make. If you erect a wooden building in one corner it need only be 12 feet long by 6 deep. The door should be at one end of it, and not wider than is necessary for a man to go through. It should be the height of the building, not less than 7 feet. The laying-boxes, three in number, should face the door, and the perches should be in the sheltered part, and not more than 2 feet from the ground. If the house has a window so much the better. The floor should be of gravel, and there should be holes for ventilation all round the top.]

CHICKENS DESTROYED BY A HEDGEHOG.—Perhaps some of your readers may not be aware of the destructive qualities of the common hedgehog. It is one of those unhappy animals that are always killed, if not tortured, by country lads. If you ask them why, they are immediately ready with a host of accusations, which I had hitherto considered as absurd and incapable of proof as the supposed venomous nature of toads, slowworms, and other innocent reptiles; but this year I have had evidence to the contrary. It was observed night after night that a chicken was taken away from a brood about a week old, which was placed under a coop in the rickyard. As the yard was known to be infested with rats, the loss was attributed to them; so the hen and her chickens were removed and placed under a window where the

man servant slept. In the course of the night he heard a great noise, the poor hen cackling loudly in her fury and terror, and apparently making vain attempts to save her young. He accordingly went down, and on raising the coop, which was a large and heavy one, he discovered, to his great surprise, a hedgehog inside, in the act of committing depredations on the flock. The hedgehog must have raised the coop to get in, and thus displayed at once its strength and its predatory character.—S. L. J., *Cornwall*.

BRIDLINGTON AGRICULTURAL SOCIETY'S POULTRY SHOW.

WEDNESDAY, July 29th, being beautifully fine, and Bridlington having the extra attraction of the seaside, the twenty-eighth annual Exhibition was unusually well attended. Most of the classes had filled well, and pretty good competition was expected.

The show of poultry was an average one, the Hamburgs, Dorkings, Cochins, and Game being the best represented, both in point of numbers and quality. Below is a complete list of awards.

COCHIN-CHINA.—First, E. Smith, Middleton. Second, E. Witty, Cottingham. *Cock*.—Prize, T. C. Trotter, Sutton.
DORKING.—First, O. A. Young, Driffield. Second, E. Smith. *Cock*.—Prize, R. M. Stark, Hull.
SPANISH.—First, R. M. Stark. Second, O. A. Young. *Cock*.—T. C. Trotter.
GAME.—First, H. M. Julian, Beverley. Second, C. Webster, Ouswick. *Cock*.—Prize, F. Smith, Driffield.
POLANDS.—First, R. Lott, Woodmansey, Beverley. Second, O. A. Young.
HAMBURGS (Golden-spangled).—First, H. A. Hudson, Ouselife, York. Second, W. Horner, Driffield.
HAMBURGS (Silver-spangled).—First, C. Campiing, Cottingham. Second, T. C. Trotter.
HAMBURGS (Golden-pencilled).—First, W. Gofton, Driffield. Second, H. Holmes, Driffield.
HAMBURGS (Silver-pencilled).—First, J. Elton, Cottingham. Second, T. C. Trotter.
BANTAMS (Any variety).—First, R. M. Stark. Second, Miss E. Creyke. *Cock*.—First, R. M. Stark. Second, W. Gofton. —*Chickens* (Distinct variety).—First, J. Yates, Hunnauby. Second, H. Elvidge, Leven Carr, Beverley.
GESE.—Prize, O. A. Young. *Goslings*.—Prize, T. Darrell, West Ayrton.
TURKEYS.—First, T. Dawson, Poundsworth, Driffield. Second, E. M. Stark. *Poult*s.—Prize, T. Dawson.
DUCKS (Aylesbury).—First and Second, O. A. Young. *Ducklings*.—Prize, T. Darrell.
DUCKS (Any variety).—First, M. Appleby, North Burton. Second, O. A. Young. *Ducklings*.—Prize, M. Appleby.
GUINEA FOWL.—First, H. Merkin, Driffield. Second, O. A. Young.
PIGEONS.—Tumblers.—Prize, B. Leason, Driffield. *Fantails*.—Prize, F. Key, Beverley. *Carriers*.—Prize, R. Baker, Hunnauby. *Jacobins*.—Prize, F. Key. *Any distinct variety*.—Prize, F. Key.
RABBITS (Any breed).—First and Second, O. A. Young. *Fancy Rabbit*.—Prize, J. Season, Driffield.

YORKSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE Poultry Exhibition of this Society came off at South Stockton on the 5th, 6th and 7th ult. In point of numbers the entries were much the same as in previous years, and in many of the classes there was a remarkably good competition. The Spanish, Dorkings, and Hamburgs contained many pens of striking excellence.

For *Spanish*, Mr. Beldon obtained the first in the class for old birds, and Mr. Rodbard second, the latter winning, also, the prize for chickens with a very fine pen. His old birds might, perhaps, have been more successful if the hens had been in better condition, and the cock's forehead had not shown the injurious effects which age generally produces in this breed.

Taken altogether the *Dorkings*, perhaps, were the best part of the Exhibition. Mr. Whitwell was first for old birds; and the prize for chickens was given to a very good pen belonging to the Rev. Mr. Newton.

The entries for *Game* were hardly so numerous as is generally the case at the Yorkshire Shows, which may, probably, be attributed to the fact that at this season few birds are in the high condition so essential in this breed.

In the *Hamburg* classes there was a very keen competition, especially between the birds of Mr. Dixon and Mr. Beldon, and their merits were very equally balanced.

In the class for Golden-spangled *Hamburg* chickens, Mr. Dixon was particularly unfortunate, as he exhibited a pen which would have won with ease, but the cock was disqualified, as he was suffering severely from roup.

There were some remarkably good *Ducks*, especially Mr. Kell's Aylesburys and Mr. Dixon's Rouens.

SPANISH.—First, H. Beldon. Second, J. R. Rodbard. Highly Commended, S. Burn. Commended, J. Shortrose. *Chickens*.—Prize, J. R. Rodbard. Highly Commended, H. Beldon; S. Robson.

DORKINGS.—First, G. C. Whitwell. Second, G. Smith. Highly Commended, H. Beldon; J. F. Newton. (The whole class commended.) *Chickens*.—Prize, J. F. Newton. Highly Commended, H. W. B. Berwick.

COCHIN-CHINA (White).—First and Second, G. C. Whitwell. Commended, J. Dixon.

COCHIN-CHINA (Any other colour).—First, G. Smith. Second, J. Shortrose. *Chickens*.—First and Second, T. H. Barker. Commended, F. R. Pease.

GAME.—First, H. M. Julian. Second, W. A. Wooler. Commended, F. R. Pease; H. Beldon. *Chickens*.—Prize, H. M. Julian. Highly Commended, G. W. Binns; F. R. Pease.

HAMBURGS (Golden-spangled).—First, H. Beldon. Second, J. Dixon. Highly Commended, H. W. B. Berwick. *Chickens*.—Prize, H. Pickles.

HAMBURGS (Golden-pencilled).—First, H. Beldon. Second, J. Dixon. Highly Commended, Mrs. Hemingway. *Chickens*.—Prize, J. Dixon.

HAMBURGS (Silver-spangled).—First, H. Beldon. Second, J. Dixon. Highly Commended, H. Beldon. *Chickens*.—Prize, H. Beldon. Highly Commended, J. Dixon; J. Crookes.

HAMBURGS (Silver-pencilled).—First and Second, H. Beldon. Highly Commended, J. Dixon. *Chickens*.—Prize, H. Beldon.

POLANDS.—First, J. Dixon. Second, H. Beldon. *Chickens*.—Prize, J. Dixon. Highly Commended, H. Beldon; W. Newsome.

ANY OTHER DISTINCT BREED.—First, J. Dixon. Second, F. Powell. Highly Commended, F. Powell; T. Appleton. *Chickens*.—Prize, J. Dixon.

BANTAMS (Black or White).—First, J. Dixon. Second, J. Skipper.

BANTAMS (Any other variety).—First, J. Dixon. Second, J. Stonby. Highly Commended, E. Brown; J. Shortrose; H. Beldon.

SINGLE COCKS.—Spanish.—Prize, J. Shortrose. Highly Commended, J. Dixon. *Dorking*.—Prize, F. R. Pease. Highly Commended, H. W. B. Berwick. *Cochin-China*.—Prize, J. Bell. *Game*.—Prize, G. Thompson.

HAMBURGS (Golden-spangled).—Prize, J. Dixon. Highly Commended, H. Beldon. *Hamburgs (Golden-pencilled)*.—Prize, H. Beldon. Highly Commended, J. Dixon. *Hamburgs (Silver-spangled)*.—Prize, H. Beldon.

Hamburgs (Silver-pencilled).—Prize, H. Beldon. Highly Commended, J. Dixon. *Hamburgs (Silver-pencilled)*.—Prize, H. Beldon.

GESE.—First, J. Sherwood. Second, J. Dixon.

DUCKS (Aylesbury).—First, T. E. Kell. Second, J. Dixon.

DUCKS (Rouen).—First, J. Dixon. Second, T. H. Barker. Highly Commended, H. Beldon.

TURKEYS.—First, F. R. Pease. Second, J. Dixon. Highly Commended, Mrs. Parker.

The Judges were Mr. J. H. Smith, Skelton Grange, near York; and Mr. Caman, Bradford.

DRIFFIELD AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS Show was held at Great Driffield on July 31st, and was attended by an immense number of people. The classes for horses, &c., had filled remarkably well, and in many cases the competition was very severe. There was a large show of Poultry, which, considering the time of the year, were shown in good condition.

In old *Dorkings* Mr. E. Smith took first with a very good pen; and Mr. Elvidge's pen, which took first as chickens, were very promising. The *Spanish* were pretty good, but we have seen better. There was a very good show of Red *Game* fowls, cock and two hens; indeed, not a really bad pen in the class. Mr. Julian was first with a first-class pen of Black Reds, Mr. Adams taking second with the same colour. In this class the Judges awarded two extra prizes to two well-deserving pens of Brown Reds, one of which belonged to Mr. Boyes, the other to Mr. Adams. In Red *Game* chickens three good pens were exhibited, Mr. Burgess being first, and the other two pens were highly commended. Two pens only of Duckwings were entered, and of these one only put in an appearance: consequently, Mr. Adams walked over. The Duckwing chicken class was nil. Good pens of adult and young Piles won, although their opponents were not above average. *Hamburgs* of all classes were well represented, the Silver-spangled being particularly good. *Bantams* of all sorts were only inferior. *Geese* and *Ducks* were good. *Pigeons* were good, but only limited.

DORKINGS.—First, E. Smith Manchester. Second, R. Smith, Norton. *Chickens*.—Prize, H. Elvidge, Leven Carr. *Cock*.—Prize, R. M. Stark, Hull.

SPANISH.—First, H. Beldon, Leeds. Second, J. Hepworth, Hatfield. *Cock*.—Prize, H. Beldon, Gilestead.

GAME (Black-breasted and other Reds).—First, H. M. Julian, Beverley. Second, H. Adams, Beverley. *Chickens*.—Prize, R. Burgess, Lockington. *Cock*.—Prize, H. Adams.

GAME (Duckwing and other Greys).—Prize, H. Adams. *Chickens*.—Prize, M. Burgess. *Cock*.—Prize, H. Adams.

GAME (Any other variety).—First and Second, H. Adams. *Chickens*.—First and Second, H. Adams.

COCHIN-CHINA.—First, E. Smith, Manchester. Second, R. Clark, South Dalton. *Chickens*.—Prize, T. H. Barker, Hovingham. *Cock*.—Prize, T. H. Barker.

POLANDS.—First, R. Loft, Woodmansey. Second, H. Beldon, Gilstead.
HAMBURGHS (Golden-spangled).—First, H. Beldon. Second, W. Horner, Driffield. *Chickens*.—Prize, J. Margatroyd, Bishop Burton. *Cock*.—H. A. Hudson, Ousecliff.
HAMBURGH (Silver-spangled).—First, H. Beldon. Second, S. Campling, Cottingham. *Chickens*.—Prize, H. Beldon. *Cock*.—Prize, H. Beldon.
HAMBURGH (Golden-pencilled).—First, H. Beldon. Second, W. Gofton, Driffield. *Chickens*.—Prize, H. Beldon. *Cock*.—J. Ellerby, Helmsley.
HAMBURGH (Silver-pencilled).—First, H. Beldon. Second, J. Fakner, Honnamby. *Chickens*.—Prize, H. Beldon. *Cock*.—Prize, H. Beldon.
ANY OTHER DISTINCT BREED NOT NAMED.—First, H. Beldon. Second, H. Adams. *Chickens*.—Prize, W. Gofton. *Cock*.—Prize, R. Loft.
FARMYARD CROSS.—First, H. Gouden, Bridlington. Second, J. Bilton, Cottingham. *Cock*.—Prize, G. Robinson, Frolingham.
BANTAMS (Black and White).—First, R. M. Stark. Second, G. Mosey, Skerne. *Cock*.—Prize, R. M. Stark.
BANTAMS (Any other variety).—First, W. Gofton. Second, H. Beldon. *Cock*.—Prize, W. Gofton.
GESE.—First, Mrs. Young, Driffield. Second, Mrs. Conyers, Elmswell. *Geese*.—Prize, J. Bannister, Fridaythorp.
TURKEYS.—First, Mrs. Dawson, Driffield. Second, R. M. Stark. *Poults*.—Prize, T. Dawson.
GUINEA FOWLS.—Prize, Mrs. Robinson, Nafferton.
DUCKS (Aylesbury).—Prize, O. A. Young, Driffield.
DUCKS (Rouen).—First, J. Brim, Pickering. Second, T. Baker, Hovingham. *Ducklings*.—Prize, O. A. Young.
DUCKS (Any other variety).—First, J. R. Jessop, Hull. Second, O. A. Young. *Ducklings*.—Prize, Mrs. Jordan, Eastburn.
PIGEONS.—*Croppers*.—Prize, W. Watson, Beverley. *Carriers*.—Prize, W. Watson. *Trumpeters*.—Prize, T. Rippon, Beverley. *Jacobins*.—Prize, W. Watson. *Fantails*.—Prize, F. Key, Beverley. *Tumblers*.—Prize, T. Rippon. *Barbs*.—Prize, W. Watson. *Nuns*.—Prize, F. Key. *Other Varieties*.—Prize, J. R. Trenam, Helmsley.
RABBITS (Any breed).—Prize, G. R. Young, Driffield.
Messrs. Challoner and Smith were Judges.

EGGS CHILLED DURING SITTING.

I HAVE just received your No. 118; and although I have done with poultry, so far as England is concerned, for some time, I think it but right to add my mite in reply to "Eggs Sat Upon, and then Chilled."

Sebright Bantams are proverbial for unfertile eggs. This was the cause of the addled eggs. A hen sitting on eggs from 10 P.M. to daylight would hardly be worse than a hen laying in a stolen nest, and would do no harm. I have had much worse tricks played than this, and hatched all, and in one instance a hen was kept accidentally off her nest the day of hatching until the eggs were cold, and hatched half the next morning. This was a common hen and eggs.

Of Cochins, I have had the eggs quite cold three times in the three weeks, and saved two-thirds; and just prior to leaving Hilsca a Game Bantam hen let her eggs get cold twice in the first week of sitting. My man shut her in, and the eggs getting very dirty I took them out, and washed every one, put them under a Cochin hen five days before their time, and she brought seven out of nine out; and I may also add I have had hens sit at night, and stand over and on the eggs in the day for two or three days, and had to shift them to other hens that hatched them. All these results have been with Cochin-China.

As I shall not see your Journal for some time again, I shall not be able to reply to any inquiries.

I should think from the tenth day the eggs would be more likely to be spoilt by getting cold than sooner; and the first two days could hardly be of much consequence. But chickens from eggs that have been chilled are not so strong as those that have been properly sat upon.—H. HASSARD, Major R.E., Quebec.

I AM very glad to find others are interested in the reasons for eggs not hatching. I waited until to-day, wishing to know whether a hen sitting on Sebright eggs would produce any chicks, before answering the query of "Y. B. A. Z." I purchased from Mr. Harvey Bayley a cock and three hens, Sebrights, first-class birds, and anticipated a good many chickens from them, having sat upwards of fifty eggs. They are in a large compartment of an aviary. I send a list of Bantam eggs, and time of hatching.

May 31st.—Fifteen eggs, the whole addled.

June 9th.—Five eggs under a Bantam, all addled.

June 10th.—Five eggs under a Bantam, all addled.

June 29th.—Seven eggs under a Cochin, six hatched.

July 30th.—Nine eggs under a light common hen, all addled.

August 3rd.—Fourteen eggs under a light common hen, all addled.

From the above list you will see I have not a Bantam chick this season, a serious disappointment it is. The whole of the eggs except those whose time of hatching was the 29th of June, were quite addled: therefore, in my opinion had been good eggs. Than the six hatched I never saw stronger chickens, but the clumsy Cochin managed to trample the whole to death before a week. No hens could sit better or closer than all the above.

I have now sat a hen (not on Bantam eggs) as an experiment, numbering the eggs 1 to 9. I placed the eggs under her at 10 o'clock at night, and on the following night at the same hour I took No. 1 away and replaced it at 10 o'clock the following morning. At 10 o'clock at night I took No. 2 away, and returned it at 10 the following morning. No. 3 the same, and I purpose with the remainder to give three days between, and chilling each twelve hours.

The result of this experiment I shall be happy to send you, if worth your notice. I have been thus particular in naming the time I purpose chilling the eggs, as probably out of your numerous correspondents you will have some who may feel inclined to try the same plan, and might change the hours of chilling, &c.—EVESHAM.

[We shall be very much obliged by a report of the result of your experiment, and wish some of our correspondents would institute similar experiments, and furnish us with the results relative to other varieties and kinds of poultry, including Turkeys, Geese, and Ducks.—EDS.]

FOUL BROOD—DESTRUCTIVE EFFECTS OF CHLOROFORM.

I AM glad to hear the "DEVONSHIRE BEE-KEEPER" has found out the cause of his bees dwindling away; and would he be good enough to say what is foul brood, and the cause of it, and how it would be known?

I observe you recommend chloroform for bees. I am afraid it will be found not to answer, as I tried it with two hives a few years since and it killed every bee; besides, the honey-comb killed every bee that went on it, and the hives were not fit to use for a long time after, and the honey poisoned all the bees I gave it to. It is a very curious chemical and absorbs the moisture from the atmosphere, so that you can never get it twice alike, and consequently, the quantity you recommend, if good, is too strong. I would advise your correspondent to use the fungus instead; and if properly done, putting the bees up with a bee-cloth and keeping them in a warm place, if the weather is cold, they will soon come round, and you will hardly find one dead.—B. B.

[Foul brood is, as its name implies, a disease which attacks the young larvae in their various stages of development. At first only a few die, but as these putrefy in their cells the infection spreads, until very few bees arrive at maturity, and the stock dwindles and ultimately perishes. The cause of its outbreak among my bees was, as I have before stated, my unwittingly making use of the combs from infected cottage-hives. German apiarists attribute it generally to the use of American or West Indian honey for feeding; and if they are correct in this, it probably arises from the disease being prevalent in these countries, and much of the honey exported being, therefore, tainted with its fatal virus. The subject appears to me of such vital importance, being the probable explanation of a great many hitherto-inexplicable failures in bee-keeping, that, with the permission of the Editors, I intend entering upon it at some length, and quoting the opinions of the most reliable German and American authorities.]

I can indorse all that is said as to the murderous effects of chloroform upon bees. I am of opinion that the late Mr. Payne never himself submitted it to the test of experiment, and am satisfied that if he had survived to edit the enlarged edition of his very useful little work, he would have expunged the passage quoted from page 27, and very probably have substituted an emphatic condemnation. I have also reason to believe that fumigation by fungus shortens the lives of bees subjected to it, however perfectly they may appear to recover at the time, and is, therefore, but one degree less mischievous than chloroform. No humane bee-keeper should rest satisfied until he has mastered the art of

driving, described by Mr. Payne in page 59 of the enlarged edition, which is the only unobjectionable mode of uniting bees in common hives.—A DEVONSHIRE BEE-KEEPER.]

UNITING SWARMS.

You inserted my letter at page 483 of your last Volume. The mismanaged second swarm was made right by the union of another cast with it, which was accomplished by turning up the first tenanted box, and, after well sprinkling with syrup and a whiff of smoke, dashing the new comers into their midst. The union was successful without any fighting, but the strengthened stock became very irritable.

The strong stock, which was weakened by transposing, was strengthened again by the union of a good swarm. It was too heavy to handle readily, but the junction was effected by sprinkling the swarm with syrup an hour or two beforehand, and at the time of union dashing out the bees and gently lifting the old stock over, having first given a whiff of smoke. The union was peaceable, and I have since obtained some fine honey; but for several days the bees clustered largely outside the hive. These unions were of bees in common close-top hives. Another union I made much more easily with a stock in a bar-box by moving the crown-board, and, after sprinkling both stock and swarm, dashing the bees on the top of the exposed bars. I have resolved to renew my apiary and substitute frame or bar straw hives for the old close-topped ones. Having purchased of Messrs. Neighbour a Woodbury straw frame-hive, I felt disappointed there was no window. Are windows useless in such hives?

I have used this season a little contrivance for emptying supers of the bees, and have found it exceedingly convenient

- a. The glass trap, a vase with the foot broken off, leaving a half-inch hole where the bees descend at c. The glass a is about 5 inches long.
- b. A block of wood in two pieces, hollowed out to fit the bulb of the glass, and held together by an elastic band.
- c. Thin adapting-boards with four-inch holes.
- d. The super to be emptied.
- e. Empty box placed on a floor-board, or on the deprived hive n n.

and perfectly effectual. It is made of a broken vase of glass, and is used by fixing it in a block of wood and placing it, mouth downwards, in an empty box, which may be placed over the deprived hive if convenient, so that the bees as they drop out of the trap fall into their own hive, and at last leave the spoil at the bee-master's pleasure. The apparatus may, perhaps, be best described by giving a sectional outline of the whole as in use for emptying a super.—A. B. C.

CHLOROFORM FOR STUPIFYING BEES.

CERTAIN of your subscribers have desired information relative to chloroform, and have been referred to "Payne's Bee-keeping" for directions as to its use in stupifying bees. Few persons, perhaps, had more intercourse with the late

Mr. Payne, particularly in his latter years, than I had; and I think there is some mistake, if it is to be inferred that he advocated the employment of any such agent, for I know well how much he was opposed to it, notwithstanding the words following attributed to Mr. Payne at page 18 of "Bee-keeping."

"This plan (chloroforming) possesses a great superiority over the usual mode of briar-stoning, as none of the bees are killed; and over the more modern plan of fumigation by fungus or puff-ball, inasmuch as it is far less trouble." It seems odd enough that the expression "more modern plan" should here be applied to puff-ball, used for centuries, probably before chloroform was known at all for any purpose.

With the pen in my hand allow me to commiserate our friend Mr. Woodbury on the lamentable account he gives of his apiary. Though the particular disease (which I believe to be an entirely artificial one) under which it is suffering never came within my own observation, I feel inclined to endorse every word at page 98 from the pen of your excellent correspondent J. Lowe. There is an old saying among schoolboys, "We cannot eat our cake and have it too."—H. TAYLOR, London.

FAILURES IN BEE-KEEPING.

THE scientific apiary of "A DEVONSHIRE BEE-KEEPER" has come to grief, and "AN OLD-FASHIONED BEE-MASTER," of Finchley, rejoices accordingly, congratulating himself that he has never advanced one step beyond the wisdom of his forefathers. Let him do so, and welcome. I can at any time, if I feel so disposed, retaliate by crowing over one of the many old-fashioned bee-masters who come to me to pour out their tale of woe, and look for sympathy and assistance at my hands. What I wish to point out is that his quotations from Golding and Taylor are quite beside the mark. I have never urged any man to attempt scientific bee-keeping who has not the inclination and ample leisure to attend to it, nor am I one of those charlatans who, from interested motives, attribute success to any particular kind of hive. I have contrived a hive which offers, as I believe, peculiar facilities for scientific bee-keeping, but I have at once made it public for the benefit of others, without the slightest thought of either fee or reward for so doing. I publish my experience for the information of all, and should take shame to myself if I concealed my failures and blazoned forth only my successes. Had our forefathers been of the same stamp as "AN OLD-FASHIONED BEE-MASTER" bees would never have been domesticated at all, nor would even the wild honey have been appropriated by man, since probably the first would-be robber of a bee's nest got well stung for his pains, and was crowed over by all the do-nothings of his acquaintance.—A DEVONSHIRE BEE-KEEPER.

"A DWINDLING APIARY."

WITH much sympathising interest I have read the lamentable account given of his apiary by your esteemed correspondent, "A DEVONSHIRE BEE-KEEPER." Can there be any other way of accounting for the disappointment which he has experienced except on the supposition that some epidemic has visited his apiary? Why should not bees be subject to some such occasional visitation of disease as well as other animals, including man himself? And is it not possible that the continued use of artificial food in his apiary year after year, deficient in some important particular of nourishment or stimulant, may have induced a state of weakness in the bees themselves, or have occasioned some ill smell about the hives or combs which has tended to the same result? If our Devonshire friend's and Mr. Fairbrother's experiences had not been (yet are they?) exceptional, one might have attributed the evil to the wretched seasons for bees which have recently prevailed. Till quite the middle or end of June, this year has proved little better than those immediately preceding it. At that time I was almost in despair, few of my hives appearing to thrive, while I met with continual disappointment (as your pages have already told) in regard to queen-rearing. Since then a decided improvement has set in; my bees have raised several Italian queens, while others have swarmed naturally—rather too

freely perhaps. I have, moreover, begun to reap my honey harvest in the shape of 20 lbs. of first-rate honeycomb—about a third part of the estimated yield of my apiary.

If our friend's apiary consisted of English bees it were easy for us to make up his loss; but who can (this year at least) supplement his diminished Italian stock? I sincerely hope that we may yet hear that he has well saved a goodly number of his hives.—B. & W.

[I cannot but acknowledge with gratitude the kind sympathy of so accomplished an apiarian as "B. & W." To him and to many others who have expressed themselves in a similar manner, I beg to tender the warmest thanks of—A DEVONSHIRE BEE-KEEPER.]

MODERN BEE-HIVES AND FORCED SWARMS.

I THINK your correspondent, "AN OLD-FASHIONED BEE-MASTER," takes it for granted, rather than proves, that the modern way of managing bees is inferior to that "non-intervention policy" which he himself prefers. I started in the old way myself, and only abandoned it gradually, as I became convinced that only the hives were my property, the bees being free agents. Since I used bar-hives the case is altered, my little friends having to modify their instincts so as to fall in with my views. I am sure the majority of bee-keepers would be sorry to learn the sad state of "A DEVONSHIRE BEE-KEEPER'S" apiary; but few will ascribe it to scientific principles of management. Besides, this one case—a mere accident, in fact—cannot decide the question raised by your correspondent. How many of the numerous apiarians who manage their bees in the modern way have been so unfortunate as this, or more unfortunate than their neighbours of the old school? And, on the other hand, are there no disasters in old-fashioned apiaries? How many stocks domiciled in old-fashioned hives dwindle away without their proprietors even knowing why?

Your correspondent's quotations from Mr. Golding and Mr. Taylor do not support his opinion at all. The honey harvest is according to season, of course, and bees will store as much in old-fashioned as in modern hives; but it is not so available, and, therefore, not so useful to the bee-master. Such hives are not, as Mr. Taylor well expresses it, "convenient in form and management for the intended purposes." No doubt bees can manage their own affairs in their own way. Nature is equal to her own work—the propagation and preservation of the species; but it is no part of her design to assist the bee-keeper in taking honey—he must rely on his own intelligence to do that, and will act wisely to avail himself of the accumulated knowledge of his predecessors and contemporaries, and of any aid which science can offer.

A few words about forced or artificial swarms may not be out of place. Many bee-keepers entertain a dislike to them, which I cannot but consider a prejudice; for nearly all the most distinguished apiarians, both English and foreign, are in the habit of making them, and have pronounced in their favour. I have always found them successful myself. If judiciously and carefully made they can hardly fail, and have many advantages to recommend them. Leaving out of the question all scientific experiments, and the propagation of Ligurians, it is surely better—supposing that the bee-keeper wishes to have swarms at all—to get them early, instead of waiting till the honey season is nearly over, with, perhaps, several weeks of anxious watching. I have made six this present season, four with old queens, and two with brood-combs only. Both they and the four old stocks (one Ligurian) have done very well. The honey season here has been unusually good and long, and I have taken a fair quantity, but not nearly what I might have done, had I made honey my chief object, instead of Ligurianising; but the temptation to have them all of the superior variety proved too strong for me.

There are several ways of making forced swarms, all good in their way; but I think Mr. Langstroth's, described in your pages last year, is the best. They may be made without a queen, by giving them combs containing eggs and young brood instead; but the more usual way of taking the old queen with the swarm is better, as it then exactly resembles a natural swarm.

The amateur should be quite certain that he has the queen. Most of the failures that occur arise from not having her. There ought to be no such failures. In bar or frame-hives she should be looked for till found, which sometimes involves a good deal of patience. In common hives it is well not to be satisfied with driving what are thought enough bees for a swarm. The notion that the queen is among the first to rush up is too generally acted upon. No doubt she often is, but, on the other hand, she often is not. I would advise to drive them all, then placing the old hive where it stood before, remove that containing the bees a few yards away, and unstop the entrance. The worker bees, but not the queen, will rush out and return to their accustomed stand. When enough have left, the stopper may be replaced, and the swarm removed some distance away.

I should recommend your correspondent, "A CONSTANT SUBSCRIBER," and all other bee-keepers, to avoid using chloroform for stupefying bees. When so treated they return to semi-animation only; and I always found, on adding them to other stocks, that they were ruthlessly put to death, as invalid members of a bee-community usually are. "A CONSTANT SUBSCRIBER" should drive his bees; there would be no difficulty with good heavy hives, such as he describes.—JOHN P. EDWARDS, *Shirleywich, near Stafford.*

OUR LETTER BOX.

HARD SWELLING AT THE CORNER OF BANTAMS' EYE (C. F.).—We should advise lancing in the early stages before the swelling becomes hard. It is not a disease we are acquainted with, except in old Spanish hens. We imagine it comes in the first place by a froth or gum in the corner of the eye; that, we think, would be the time to hinder it by keeping it well washed with cold water and vinegar. If that failed we should not hesitate to remove it and to cauterise the wound in the early stage. We assume they are otherwise in good health.

SILVER-SPANGLED HAMBURGH HEN RAVENOUS (Poulet).—The hen in question is in a diseased state, and cannot, therefore, digest food sufficiently to satisfy her, or to cause her to thrive. Separate her from the others; purge her freely with castor oil, a table-spoonful every other day for a week; feed her sparingly on ground oats mixed with water, and rather slack than otherwise. After the week give Baily's Pills. The evacuations caused by the oil will probably be green and slimy, and there will be no cure till this ceases, and the excrements are brown, brown and white in colour.

REPORTS OF POULTRY SHOWS (C. T. Bishop).—The Editors endeavour to have reports of all important poultry shows; but it often happens that they cannot have a reporter at those not metropolitan, and then if the Secretary or some friend does not transmit a prize list the show is not reported in the Journal. We shall always be obliged by a prize list being sent to us, as it prevents disappointment.

LUMP IN SPANISH HEN'S THROAT (Constant Reader, York).—You cannot do wrong in removing the substances, and cauterising any wound it may cause. It is the only cure, and if it fails the bird will at last die of the ulcer; but we do not think she has the roup, as we never saw a roupish Spanish fowl.

WINTERING BEES—DEPRIVING-HIVES (W. B. C., Denton).—We know of no precautions you can take to insure the bees in your Nutt's hive surviving the winter, except making sure that they have a sufficient store of food. We do not think it necessary, or even advisable, to take bees indoors in our climate, whatever may be done on the continent. The Woodbury frame-hive might answer your purpose; but in this matter you should judge for yourself.

AGE OF QUEEN BEES.—In answer to "A. W." about the age of the queen the printing is quite correct, nor is it the only case of queen-bee being of that age. A gentleman in our place had several as old, which did well to the last.—A LANARKSHIRE BEE-KEEPER.

CANARIES AND BELLFINCHES SHEDDING THEIR FEATHERS (S. A.).—If your birds are not in deep moult it is very probable that they have insects, which might be ascertained by examining in the daytime the crevices and round the edges of the door of the cages. Should insects be found, put the birds into fresh cages, as the insects cannot be thoroughly destroyed in the old ones. Take care to change the birds from the old cages to the new ones in the daytime, as the insects do not leave the wood until night to infest the birds. Let the birds have plenty of fine sand and a bath every day. Wash the crevices of the old cages with a strong solution of salt and water and afterwards with clean water, which will destroy the insects, and then return the birds to them again, examine the fresh cages as well as the old ones, change the birds from one cage to the other twice or three times a-week, and if any insects appear repeat the washing.

AUSTRALIAN GRASS PAROQUET (*Ornithophilus*).—No. 50 is out of print, but we reprinted the directions for the management of these birds in No. 111. We shall always be ready to answer your queries.

LONDON MARKETS.—AUGUST 10.

POULTRY.

The supply of Poultry now exceeds the demand, and prices cannot maintain themselves.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 73.2°, and its night temperature 50.4°. The greatest heat was 92°, on the 18th, 1842; and the lowest cold, 32°, on the 21st, 1850. The greatest fall of rain was 0.95 inch.

SEEDLING GLOXINIAS.

THE information asked for by a correspondent regarding the treatment of seedling Gloxinias appears to include the method of sowing the seed, as well as the after-management of the young plants, it may perhaps be as well to begin at the beginning.

About the middle of February is a good time to sow Gloxinias. If deferred till further on in the season the chances are against their flowering, or forming bulbs sufficiently strong to keep well through the winter.

A well-drained pot or seed-pan should be filled nearly to the brim with soil consisting of two parts loam, one part peat, one part well-rotted leaf mould rather finely sifted, and one part sand. The top half-inch of soil should be passed through a sieve of quarter-inch mesh, and the surface made level and smooth for the reception of the small seeds. Thick sowing should be avoided, because the plants become crowded and drawn, as well as more likely to suffer from damping-off before they are large enough for being transferred into pots or pricked-off into pans. For the same reason it is a great error to sow any similar seeds thickly, for when plants become drawn and spindly in the seed-pan it requires some trouble to get them stocky again, and in the case of some things it is a hopeless task. Gloxinias are very apt to fog-off in patches when they are thick in the seedling-pot. When the seed is sown, and just sufficiently covered to hide it, the surface of the soil should be nearly half an inch below the mouth of the pot. After being watered through a fine rose, plunge the pot or pan in a gentle bottom heat where such can be afforded. They will, however, germinate freely in a temperature of 70° without bottom heat. Either a bell-glass or a pane of glass should be placed over the pot to prevent rapid evaporation of moisture and help to maintain a uniform temperature. Alternations from drought to moisture must be avoided, or the young plants may never make their appearance at all. A medium state of moisture, with as few applications of water as possible, should be the aim. With this view, in the rearing of seeds it is a good plan to place the seed-pan in a saucerful of water, when, by the action of capillary attraction, the soil is kept more uniformly moist than when water is applied at the surface in the usual way. However, the Gloxinia is by no means precarious in germinating, and with ordinary care is sure to vegetate if sown and treated as has been directed.

When the young plants make their appearance the bell-glass should be tilted up at one side, and more air admitted by degrees, till the glass be entirely removed. Care must then be taken that the young plants are not exposed to the sun, and that the surface of the soil does not at any time become merely dry; and although shaded

from direct sunshine they should be kept on a shelf near to the glass; and, if they have come up thickly, they should either be thinned out, or pricked-off into pans before they become drawn, or run the risk of damping-off.

When they are large enough to be handled conveniently they should be potted into 2½-inch pots; and if it be an object to flower as many of them as possible, with the view of selecting the best varieties, two or three may be put into one pot; but if room can be afforded, it is preferable to pot them singly. The soil used for potting them may be exactly the same as that recommended for sowing the seed, only neither the loam nor the peat should have any of the fibre sifted out of it. When potted and well watered they may be placed in a pit, frame, or stove, where they can have a night temperature of 65° to 70°; and if they can be plunged in a bottom heat of 75° to 80° they will make more rapid progress than when simply placed on a shelf or the surface of a bed. If placed on a shelf in the stove some moss or sphagnum should be placed under and about the pots to prevent them from drying up too quickly. Wherever they are put they should not be placed in the shade of other plants, but near the glass, where they can be shaded from the sun, and have a kindly moist stove temperature. If treated thus they will soon make nice stubby-leaved plants, and will require being shifted into pots a size larger. Four or five-inch pots will be quite sufficient for the first year. A little old well-decomposed cowdung may be added to the compost already named with advantage. They should still be kept in a stove temperature, and be shaded from the direct rays of the sun in the middle of the day. Under such circumstances they will grow rapidly and make nice flowering bulbs for next season, and some may throw up a few flowers the first season.

When Gloxinias expand their first flower they should be gradually hardened-off till removed to the greenhouse, where they will form a show in the height of summer and continue to flower a long time. They must, however, be placed in a position where they will not be exposed to drying currents of air, and they bloom best in a temperature a little warmer than is generally maintained in a greenhouse.

When done flowering and the foliage shows symptoms of waning, water at the root must be gradually withheld, and the soil allowed to become drier and drier till they are entirely set at rest for the winter. The best winter quarters for the bulbs is that where they will be free from drip and not be exposed to a temperature that ranges much below 55°.

In spring, the time to start them must be regulated by the time they are required to flower. If started in February they will bloom in June. They should be entirely shaken out of the old dry soil and put into four-inch pots, or they may be placed at once in six-inch pots, in which they will make fine plants and yield a large crop of bloom. I have never found that much is gained by putting Gloxinias into large pots, except in the case of old and large bulbs, which, of course, must

have pots proportioned to their size. Eight-inch pots will grow large bushes, that will flower profusely and in succession. It is always preferable to allow the bulbs to show signs of starting in spring before they are either shaken out or started. When they have sprung about half an inch is a good time to shake out and repot them; and when the soil in which they are put is moderately moist they should not be watered for a week or so after being potted, but may have a gentle dewing with a fine-rosed pot or syringe. Their treatment the second year may be precisely that recommended for the young seedling plants. Gloxinias are among the easiest of plants to grow. A moist warm stove and slight shade from the sun while in a growing state, and when in bloom a warm greenhouse of intermediate temperature, suit them best.

Being of easy culture, and many of the varieties of exquisite beauty, they are among the most useful plants an amateur can grow. They remain in bloom a long time in summer, and in winter they are easily stored away, giving no trouble till they show signs of motion in the spring.—D. T.

GLADIOLUS REINE VICTORIA.

I SHOULD be very sorry to mislead any one, but it would appear from your correspondent "G. P. O.'s" letter that I must be doing so in respect of the above bulb; and yet I can only say that when M. C. Verdier mentioned three francs as its price, I mentioned it afterwards as a question—"trois francs?" It may be circumstances have led him to alter with regard to the number of bulbs. I still must beg leave to doubt whether he has more than a thousand flowering bulbs of it for sale. I may take the opportunity of saying that John Waterer (Souchet) is a fine noble flower of the Linné type, very showy and good. Impératrice Eugénie has gone wrong with me, and is miserable; but there is something the matter with the bulb, I think.—D., Deal.

CAULIFLOWERS.

SECOND only to the Pea in point of excellence and utility, a regular supply of this vegetable is a desideratum. Although its culture is easy and for the most part well understood, yet there may be some who do not know how it happens that his neighbour has Cauliflowers from June 1st to January 1st when his own seldom head before July, and the first frost often prevents his having Cauliflowers in October. It is for the information of such persons that I shall make some remarks on the culture of the Cauliflower; and if any know of processes either more speedy or affording better results an account of them will be gladly received, for it is only by the exchange of opinions and experience, collected in a diversity of climate and soil, that we can hope to become enlightened in garden matters, and able to follow our calling under varied circumstances.

Cauliflowers are in season, under ordinary circumstances, from midsummer until the first severe frost cuts them off. Six degrees of frost will not destroy the heads if not exposed directly to the influence of hot autumn days followed by dew at night. Providing the leaves are turned over the heads to keep them white and close and to protect them from white frosts, Cauliflowers rarely suffer from October frosts—at least, not oftener than once out of five consecutive seasons. Notwithstanding that the Cauliflower can neither be had early nor late without artificial protection, I will treat of their cultivation both with and without protection.

WITHOUT PROTECTION.—For Cauliflowers the situation cannot be too open, nor the soil too rich and deep. The ground should be dug deeply—trenching is better—and thrown into ridges early in autumn if it is in the least tenacious. On heavy soil the manure, which must be liberally supplied, is best given in a raw or undecayed state, for it then helps to admit atmospheric air and to keep the soil open. It is best applied in the autumn. Well-decomposed manure is best for light soils, and that of a cold nature, as cow or pig manure, is to be preferred. Fresh stable, hen, or pigeon manure stimulates the plants too much, causing a superabundance of leaves without giving a correspondingly large compact head. The ground having been ridged in

autumn should be thrown level in February and manured, if that was not done in the autumn.

Early in April prepare a bed of rich pulverised soil, leveling it and making fine. On that sow thinly Frogmore Early at one end and Dwarf Erfurt Mammoth at the other, and cover lightly with fine soil. If the ground is dry the bed must be watered in the morning. A few spruce branches that have cast their leaves laid over the bed will answer the twofold object of affording a little protection from sharp frosts and keeping linnets, chaffinches, &c., which are very partial to Brassica seeds, from pulling the seedlings up as fast as they appear. When the plants have two rough leaves prick them out to gain strength and to cause them to bear transplanting better; and if they be properly supplied with water they will be ready to plant out in three weeks after pricking-out.

In planting out stretch a line along the plot to be planted, a foot from the outside, and with a hoe draw a deep drill. Then with a trowel cut round each plant, by which means you will be enabled to lift them with a nice ball. Plant with the trowel, putting the plants in the drill quite up to the lowest leaves, and 2 feet apart and the same distance between the rows. Water immediately after planting and the plants will never droop, whereas, if they are pulled up and planted with a dibble fully a fortnight is lost; and if dry weather ensue after planting they are sure to head prematurely, often occasioning the loss of the crop. The less the plants flag the better will they root; therefore, copious waterings should be given until they become established, and even afterwards they ought never to become dry at the root; but in hot weather, after the plants are earthed, the drainage of the dunghill and slopes of any kind may be given between the rows, which is far better than applying such manure close to the stems, the spongioles of the roots being actually at some distance off. A good soaking between the rows, say twice a week, is sure to reach the majority of the roots and prove very beneficial. Where other liquid manure cannot be had, two ounces of guano to a gallon of water makes a good substitute, and is very favourable to the development of most crops when luxuriance is the object.

Hoeing between the rows should be frequently practised, drawing a little soil towards the stem of the plants each time until the leaves nearly meet, when the final earthing-up must be given. The Cauliflower emits fibrous roots from the stem, and earthing-up materially aids in inducing the plants to do so, in addition to keeping them from rocking in a gale. It is necessary to frequently stir the ground between growing crops to prevent the surface cracking in dry weather, which it will do after heavy rains, and we all know that rain runs off instead of entering a dry, baked surface. We must, therefore, have the soil in such condition that a shower will be made the most of, and be readily absorbed, instead of running off by the surface.

Without surface-stirring and frequent watering, unless the weather be wet, Cauliflowers cannot be otherwise than open-headed and seedy, if half the crop does not head prematurely.

Success in Cauliflower-culture depends on—1st, Having the plants pricked-out before they become drawn in the seed-bed; 2nd, Keeping them growing freely, shading and watering well after pricking-out; 3rd, Planting them with a ball, or injuring the roots as little as possible; and 4th, Keeping them in free growth at all stages, by copious waterings and surface-stirring. Attention to these points and those already adverted to, as well as the hints to follow, cannot fail to result in large, firm, close, well-flavoured Cauliflowers.

When the head fairly shows itself, bring a few of the lowest leaves over it from opposite points; and to cause them to remain in the position most likely to shut out the rain and exclude sun, break the midrib of the leaf at one-third of its length from the bottom. This is done to make the head as white as snow and delicate in flavour, and unless the leaves are thus turned over the head is sure to be yellow, open, as strong as a Turnip in flavour, and emitting a small anything but agreeable.

In unprotected gardens three sowings are enough—viz., in the beginning, and again in the end of April, and on or about the 24th of May. The first sowing will produce heads in

August, the second in September, and the last in October. The Stadtholder, Asiatic, and Walcheren, are best for the second and third sowings.

WITH PROTECTION.—Fermenting material or artificial heat, frames, and hand-glasses, are the appliances.

To produce early Cauliflowers the sowing is made in August, the second week being quite early enough; and when the weather is mild a September sowing is often preferable. It is well to provide for all emergencies: therefore I will give in close detail the particulars, and nothing can represent these better than a table showing time of sowing, pricking-out, and planting. The dates are the means of fifty years observations, as noted by an old gardener, and they have been verified and practised by myself, and found to answer.

Sown.	Pricked-out.	Planted.
March 1st (on hotbed).....	March 29th (on hotbed)...	May 1st.
March 9th (under south wall).	April 21st.....	May 23rd.
April 8th.....	May 14th.....	June 4 h.
May 2nd.....	June 3rd.....	June 20th.
May 24th.....	June 21st.....	July 15th.
June 4th.....	July 1st.....	July 25th.
August 23rd.....	{ October 2nd (under hand- glasses and frame). }	April 15th.
	{ October 15th (in frame, part potted and put in a pit) }	April 20th, and May 9th.
September 3rd.....		

From the above table it will be seen that the obtaining of Cauliflowers early was well provided for. If those under hand-glasses failed, there was the second autumn-sowing to rely upon; but had these also disappointed, there was the spring-sowing on a hotbed. If all did well, the hand-glass division gave heads early in June, the potted ones followed next, beating by ten days those transplanted from the frames, and those on hotbeds were little, if any, behind the transplanted ones.

I have heard old gardeners talk of being able to have Cauliflowers all the year round, but have not been gratified by seeing it done, though I have no doubt it has been. I have cut Cauliflowers on New Year's-day, and in almost all seasons they may be had until Christmas. Snow's Winter Broccoli in mild seasons may be had in January and February, which, with Knight's Protecting, will see us into March, when Malta, a dwarf and somewhat tender kind, comes in, followed by Dilcock's Bride, Elletson's Emperor, and Mammoth, winding up with Invisible White Broccoli in May, a few of which taken up when the heads are about the size of a small doubled hand, and laid-in under a north wall, will generally be retarded three weeks, or until Cauliflowers come in from hand-glasses. I have no doubt, therefore, that some gardeners may have had Cauliflowers seven months, and Broccoli five, out of the twelve.

Cauliflowers should be pricked out under hand-glasses in rather poor soil, for the main object is to have them well rooted before severe weather sets in, and they will produce more fibres and root more quickly in a rather poor than in a rich compost. A sheltered site should be chosen, and if the plants will stand sun without flagging they should not be watered from November until the close of March; in fact, they seldom will need a watering after that given at pricking-out time to settle the earth about their roots. A dozen or more may be pricked out under each hand-glass on condition that they be reduced to three, four, or five in the April following.

Square hand-glasses, 1 foot 6 inches on the side, 10 inches in depth to what may be termed the eaves of the hand-glass, and with a moveable top, are the description to be preferred; for when the top is taken off the bottom is left to shelter the plants from cutting winds, though exposing them well to the air. With the other kind of hand-glasses the plants are often exposed to chilling draughts, and frequently do not form anything like a head afterwards. Plants are acted on by draughts similarly to animals. Sudden changes in temperature give colds to animals; and so in plants—sudden changes are hurtful, and if long continued cause the death of the subject.

Whenever the temperature is above 32° Cauliflowers should have air, and when it is above 40° the lights of frames or the tops of hand-glasses should be taken off and not put on again until from frost or heavy rain the doing so becomes an imperative necessity. Cauliflowers cannot have too much air or too little water during winter, or too much

of either when growth is wanted. During severe frosts the lights may remain closed, providing the sun does not melt the snow off the glasses or thaw the frosted leaves inside. Snow should never be swept off the lights, for it is the best of all protective coverings; and when the lights are matted, which they should be in severe weather if no snow falls, the mats should not be removed until the plants are thoroughly thawed; otherwise, the sun shining upon the frosted leaves will have the same effect upon them as warm water has upon frosted greens. Frosted plants of any kind cannot thaw too slowly, otherwise the tissues burst. The soil should be frequently stirred and every possible means taken to promote a healthy state, and then the plants will thrive. They cannot flourish in an impure atmosphere, nor form sturdy growth in a close frame.

After March the lights should be taken off frames and the tops of hand-glasses removed every morning before breakfast, and put on again the last thing before ceasing work for the day. A little fresh soil should be added as the plants advance in growth, and by the beginning of April they will need thinning. Do this as much as possible without injuring the remaining plants, which must be well watered and earthed well up. Where there is a number of hand-glasses half of them may be reduced to five plants in each, and the other half to three. Hand-glasses with five plants beneath them will come into bearing sooner than those with three, for by limiting the supply of food at command we induce early flowering.

After the 13th of May the hand-glasses may be removed altogether if they be wanted for other purposes, as ridge Cucumbers, &c.; but a few should be left over the plants, by which means a succession is certain, and heads may be cut under them in May sometimes, but with certainty in June. As the plants advance in growth earth must be placed round the stems, leaving it something like a mound with a flat top dish to hold water. Water must be constantly given at night in dry weather, or the head will be small and as soft as a puff-ball.

The treatment of Cauliflowers in frames is identical with that of plants under hand-glasses, except that they are planted out as from a pricked-out bed, and every cottager in the village may receive his score or two of plants.

In sowing in pans or frames the seeds must be scattered thinly and abundance of air given, or blacklegging (the stems damping-off near the soil), or drawn growths result. Too much water causes damping, and sudden changes of temperature induce premature heading. It is scarcely possible to have good-sized Cauliflowers from spring-sown plants before July, though I have heard many gardeners advocate spring-sowing in preference to autumn-sowing, even insinuating that they can obtain as good heads and as early from one as from the other. I have tried both plans, and never could grow anything worth calling a head before the middle of July from a spring-sowing, though I certainly have had some small heads open enough for anything from similar sowings; but they were only fit for stews. Spring-sown plants make a first-rate succession to autumn-sown, and for that reason a sowing in heat in spring is desirable.

Passing over the treatment of after-crops, which has been given at an earlier stage, I will take October, when the plants from the June sowing will have nice heads forming. When these are about half the size they would attain if left growing, bring all the leaves together over the heart and tie them with matting as for blanching Lettuce, then with a spade cut round each plant at 9 inches from the stem, not leaving any uncut part. Sixty plants will be ample to serve in this way, and should no frost greater than 10° happen no injury will result to the heads, which will be retarded a fortnight or three weeks. At the same time select one hundred plants, more or less according to the size of the establishment, and with a spade cut down the depth of the spade on three sides of the plant, and with the last cut lift up the plant and carry it just as it is to a north border, where a trench has previously been opened to receive it. In this place put the plant, leaning it with the head towards the wall, and cover the stem quite up to the leaves in addition to covering the roots. Tread the soil gently down, and put the plants as closely together as possible without literally being one upon the other. The plants, it should be borne in mind, must not have heads larger than one-quarter

of the size they would be when full-grown, nor less than a medium-sized Apple. If the ground is very dry water may be given, but not much, and no more ought to be allowed from the watering-pot. The leaves will flag and cover the head, which is desired, and the head will enlarge though the leaves decay, and these must be removed whenever they do so. When frosts occur cover with clean straw—litter will do—but take the covering off in mild weather and increase or decrease its thickness according to the mildness or severity of the weather. No frost that occurs in our climate oftener than once in half a century will harm Cauliflowers with 6 inches of straw immediately over them, for we have earth heat and one of the best of all non-conducting mediums—straw. By this plan we can eat Cauliflowers at Christmas.

An open shed is a better place than a north border for protecting Cauliflowers. There they are not liable to rot and are shielded from drenching rains. A few plants taken up on the approach of frost and hung in a cellar, roots upwards, will keep a long time.

Of diseases and insects there are three that attack Cauliflowers—viz., Shank or Withering of the Stem in the seed-bed, Clubroot incidental to all the Cabbage tribe, and the Cabbage Caterpillar. The first is promoted by sowing too thickly in the seed-bed, which prevents air and sun reaching the neck of the plants. It is seldom that shanking occurs in the open ground. Sowing more sparingly and giving abundance of light and air is a sure preventive of the disease.

Clubroot is engendered by sowing Brassicas on the same ground too often without change, and rarely shows itself in the Cauliflower on newly-turned-up ground. Dipping the roots in a mixture of soot and lime at pricking-out time acts as a preventive. Any plant that looks sickly should be taken up, and if on examining the root an excrescence is found it should be opened, and a grub will be seen. If this be taken out, and the roots dipped in soot and lime water and replaced in the soil, the plant will grow.

Hand-picking is the best cure for the caterpillar, and giving a small sum to children for every butterfly taken the best of all preventives.

Soot will keep snails and slugs at bay, and a liming now and then is a sure way to free the soil from insect pests, besides increasing its fertility.—GEORGE ABBEY.

SOOKS.—The following are what I would recommend:—*Early London* (Covent Garden, Improved Early London, London Particular).—A useful early kind; best for August and early spring-sowings.

Frogmore Early Forcing.—Of dwarf and compact growth, heads large and fine, flavour excellent. Best for frames and wintering in pots; stands confined air better than any other Cauliflower.

Dwarf Erfurt Mammoth.—Dwarf, about 1 foot in height, producing a large, close, compact head. White and delicate eating; best for spring-sowings.

Asiatic (Leyden).—The largest summer Cauliflower in cultivation.

Walcheren.—A good old sort, difficult to procure true; stands the winter well.

Stadtholder.—A free-growing variety; heads close, large, and firm. Best for autumn use, and a better variety than the Walcheren.

Le Normand.—Grows from 1 foot to 1 foot 6 inches high; heads medium-sized, close, and firm. A very excellent variety, standing drought well.—G. A.

VINE LEAFSTALKS GANGRENING.

In February last I planted two houses of Vines, the roots being in an outside border composed of fresh turf from a pasture, with one cartload of stable-manure, and one barrowful of rough bones to eight loads of soil. I kept the houses moist and shaded until the middle of July when the Vines had reached the top of the house. I then stopped them, removed the shading, and gave more air. In a few days the leafstalks became soft near the bud, the leaves hung down, and soon afterwards died. Hamburgs at the coolest end began first, but they all are going more or less. Pray what are the cause and cure?—VIRIS.

[You have given the Vines a border rather too rich. They should have had no shade after beginning to grow.

Your only remedy is to shade a little in the middle of the day now, so as to avoid sudden change. The Vine in general cannot have one ray of sunlight too much. See that the border is moist enough, and give plenty of air.]

FAWSLEY HALL, NEAR DAVENTRY.

"Any place but Daventry. I cannot go *there*. Why, it is five miles from a railway station, and the telegraph wires stop a quarter of a mile short of the town, because even a message per annum was considered hopeless!"

Such was a friend's response to a proposal to visit this Benaventa of the Britons, and Isannavaria of the Romans.

However, his fear of banishment was overcome; we travelled by the North Western Railway to Weedon Station, were duly met by a friend's phaeton, stayed some days at Daventry, and when we turned our backs upon the old town, the last headquarters of the king of infirm purpose before he ruined his cause on the not-far-off field of Naseby, our friend acknowledged that "there is something worth seeking beyond the reach of railway trains and telegraph wires."

Let us trace what this "something" is about Daventry. And, first, of Fawsley Hall.

There is something in a name—and there is something in bearing such a name as "Knightley of Fawsley," that must deter from unworthy conduct—something that summons to one's mental groupings all that belongs to and characterises "the good old English gentleman;" and we rejoiced when told of traits in the present baronet's character, full-worthy of one among whose ancestors was a daughter of John Hampden; and the Norman founder of whose family, "Raimald de Chenistelei," was with William the Conqueror.

Fawsley Hall is about four miles from Daventry, and is arrived at by a road of very varied beauty through the village of Badby, and the Fawsley Woods. We halted for a few minutes to search for old inscriptions in Badby Church, and though we failed in finding marble effigies of cross-legged knights, or even a single brass, yet there was one recent tablet which made one take a long breath, and think how that heart had suffered which recorded that "the angel of the house" was gone, and added, "May my two sons imitate her virtues, and thus be a blessing to their father." We passed on saddened, if not wiser, and soon were among the Fawsley Oaks, beneath which there is no doubt Hampden, Pym, and other kindred spirits had held council with Sir Richard Knightley, who then was Fawsley's lord, how best to resist the Stuart tyranny.

But it is with the garden we have more immediately to do. Our visit being a very short one, too short to enable us to enter into full particulars of the beauties and attractions of this interesting place, we shall merely notice a few of the objects that formed the greatest attraction for us.

Having been introduced to Mr. Brown, the gardener, he at once conducted us to the points which he knew would afford the greatest interest, and which brought out the most prominent features of the department under his care. Conducting us down the west side and on the outside of the walls, along a broad walk tastefully planted on either side with a profusion of flower-beds, we entered a covered walk which runs at right angles with it, and communicates from the kitchen garden to the Hall. This covered walk is one of the features of the place. Issuing from a shrubbery and plantation which separate the kitchen garden from the park, the distance between the shrubbery and the entrance to the garden is planted on either side with a hedge of Hornbeam, which has been trained over so as to form a spacious archway of beautiful proportions, and which is kept in very fine order. It is not one of those dense wild masses, with merely a passage cut through it, but is of itself a work of art, upon which no small amount of skill and labour is bestowed. Although not more than 9 inches or a foot in thickness, it is perfectly close, and affords a cool and agreeable shade. At the end of this walk is the entrance to the kitchen garden through large folding-doors, and here it was the beauties of the place were exposed to our view.

Like a first-rate artist, Mr. Brown knew well how to exhibit his picture with the most telling effect. While we were yet at the farther end of the covered way, Mr. Brown hastened a little in advance of us, and throwing open the

double folding-doors at one effort, there burst upon us such a blaze of floral beauty as quite arrested us, and made us as if to recoil with the force of the impression it made. The scene that was thus exposed was the centre walk of the kitchen garden, with ribbon-borders on either side of it 153 yards long, and 3 yards wide. Whether it was the sudden effect produced by Mr. Brown's clever overture, or the intrinsic beauty of the arrangement itself, or both combined, but we were impressed with the feeling that we never before saw two such ribbon-borders.

For the benefit of our readers we have pleasure in being able to record their composition. Commencing from the gravel walk—

1st row, <i>Lobelia speciosa</i> .	5th row, Golden Chain Geranium.
2nd „ <i>Mangle's</i> Variegated Geranium.	6th „ Lady Sale Scarlet Geranium.
3rd „ Purple King Verbena.	7th „ Countess of Cork Variegated Geranium.
4th „ Comet Sea-et Verbena.	8th „ <i>Perilla nankinensis</i> .

The same was repeated on the other side. The borders were in the very height of their beauty, and with the exception of Comet, which was a little too dwarf to be between Purple King and Golden Chain, the whole was perfection.

Immediately behind these ribbons are rows of pyramidal Pears and Apples, some of them trained *en quenouille*, and now from 8 to 10 feet high. Most of them are covered with fruit, and although they were removed into this position only two years ago, they are now perfectly re-established, and form a pretty feature behind the ribbons.

Having gone the whole length of this broad walk, and reached the opposite end, we turn to the right towards the range of houses. Here, again, our eyes were dazzled, and our breath bated. Immediately in front of the houses is another broad walk, speaking from memory, about 10 feet wide; and on one side of it another ribbon-border, if possible even finer than the other in effect, and certainly more perfect in arrangement, for here there was not a flaw to jar the harmony of the whole. It is also 153 yards long and 3 yards wide, and is arranged in the following order:—

1st row, <i>Centaurea tomentosum</i> .	6th row, Lady Sale Scarlet Geranium.
2nd „ <i>Lobelia speciosa</i> .	7th „ Jane Variegated Geranium.
3rd „ <i>Mangle's</i> Variegated Geranium.	8th „ Victoria Scarlet Geranium.
4th „ Purple King Verbena.	9th „ <i>Gladiolus brenchleyensis</i> .
5th „ <i>Centaurea argentea</i> .	10th „ <i>Perilla nankinensis</i> .
	11th „ <i>Hollyhocks</i> .

In this border the two most attractive lines are the *Centaurea* and the *Gladiolus*, the fine broad and solid-silver effect of the former fully justifying the great expectations formed of it by Mr. Beaton when first he noticed it in these pages, and the graceful stateliness of the latter forming a fine transition between the dwarf Geraniums and the tall *Hollyhocks*. At this season the *Perilla* cannot be said to make any striking effect, as it is in a measure hidden between the *Gladiolus* and the *Hollyhock*, and is intended to come in when the *Gladioluses* are over.

Never have we seen such a stock of the *Centaurea* as we did here, and from the way in which it has been used there is no doubt it will prove a permanent material for a third, fourth, or fifth-row plant of silvery character far surpassing in effect the old *Cineraria maritima*.

On the border next the houses there were beds of various forms filled in the usual way; but there was a round one that especially attracted our attention filled with Mrs. Pollock, one of those beautiful chromophyll Geraniums. This was the first time we had ever seen it in a mass, and, judging from this example at Fawsley, we do not doubt but that it will form a new and telling feature both in beds and ribbons. In the same bed there were a few plants of *Sunset*, also one of the chromophylls, but the effect produced by it in comparison with Mrs. Pollock was poor in the extreme.

The range of houses occupies nearly the whole length of the garden. A considerable extent of them is devoted to Peach culture, that part on the west side of the centre being generally forced, while that at the eastern extreme has no artificial heat, although pipes are provided in the event of being called into requisition. And here we must again compliment Mr. Brown on his skilful cultivation. These trees on the walls are the very pictures of health, vigorous without being gross, and producing a luxuriant dark green foliage, some of the leaves being from 8 to 9 inches long, and proportionately broad. The climate of this part of Northamptonshire is such that Peaches and Nectarines cannot be

grown with any degree of success against walls in the open air; but this deficiency is amply compensated for in the great success that Mr. Brown attains under glass. The sorts that are most grown are the Royal George and Noblesse Peaches, and the *Violette Hâtive* Nectarine.

In the early vinery, now nearly over, there were still some good examples of Black Hamburgh. In one of the vineries there is a mixed collection, which we believe is intended only to be temporary. Among these are—Trebbiano, Lady Downes', Golden Hamburgh, &c., but as a late sort, Mr. Brown intends for the future to rely on Lady Downes', and has accordingly planted a whole house with this valuable variety exclusively. The Vines in all of the houses have been but recently planted, and are in a state of healthy vigour.

In the Fig-house, which, too, is a mass of luxuriance, there was an excellent crop of Brown Turkey, or, as it is sometimes called, Lee's Perpetual, and one plant of another variety called Datte, a strong, indeed too strong-growing variety for house culture. It is, nevertheless, a good Fig, and is one of those varieties we find extensively in the markets of Auch, Toulouse, and Montpellier. As we get higher up into Provence, it is not so common. We doubt very much, however, if this sort, on account of its strong and robust growth, is adapted for in-door cultivation.

In the centre of the range, and standing out at right angles with the wall, are two span-roofed stoves, both of which were gay with flowering exotics, among which were large hanging-baskets of various sorts of *Achimenes*. At the end of each, and entirely covering the wall, were plants of that singular plant, *Aristolochia ornithocephala*, certainly one of the most remarkable plants in cultivation, grotesque beyond all measure. Imagine the head of a vulture, size and shape included, with an enormous scythe-shaped beak 9 inches long, with a great flapping bib or wattles under its chin 6 inches wide and 3 deep. The head and bib are of a steel grey colour, finely netted with a mahogany brown, and the beak is entirely of the latter colour. There is in these houses a fine collection of select Orchids, many of them very fine specimens, but, of course, at this season out of flower.

Our time being limited, we made but a hasty run through the Pine-pits, in which are very fine luxuriant plants; and having looked into the Melon and Cucumber-frames, we bade adieu to Fawsley, regretting our visit was so hasty, and resolving in our own minds when opportunity offers, to repeat a pleasure which afforded us so much gratification.

THE SPANISH CHESTNUT.

In reading Mr. Robson's article respecting our ancient forest trees, I thought the following remarks might not be unacceptable to some of your readers. There are to be seen growing, or at least were four years since, at Shrubland Park—the seat then of the late Sir W. Middleton, now of Sir George Brooke Bart.—several much finer specimens of Sweet Chestnut than those alluded to by Mr. Robson. They were growing by the side of a terrace-walk, and though some of them were decaying they were objects of interest to all who saw them. I am not prepared to state their exact size. One of them which I often measured was about 36 feet in circumference at the ground, and I should think that at 5 feet up it was about 21 feet in circumference, as the bottom was very much enlarged.

Some of the largest Oaks I ever saw are growing at Helmingham Hall, in Suffolk, the seat of—Tollernache, Esq.—E. WELCH, *Palace Gardens, Armagh, Ireland*.

LARGE ELM.—A fine old Elm tree, 25 feet in girth at 10 feet from the ground, is still in vigorous health at the south-east corner of Tooting Common.—H. T.

I SEE in your Journal of last week a paragraph about a large Elm at Bromyard. We have in this garden one measuring 25 feet round at 1 foot 6 inches above the ground, and 20 feet at 5 feet above the ground. It is perfectly sound, and has stood whole in limb against the heavy gales of 1858-9.—H. P. B., *Hartlebury Rectory, Kidderminster*.

CULTURE OF *DISA GRANDIFLORA*.

ACCORDING to your request I send you the following particulars respecting the course of culture I have practised in growing and flowering *Disa grandiflora*. It is now in bloom here, and a most beautiful flower it is. It has been depicted in the pages of *The Florist and Pomologist* already; but its beauty must be seen to be duly admired.

The soil I used was good sandy peat mixed with bits of charcoal, and the pot was well drained. Although the plant, it is said, does well standing in water, I found ours flourished the best when standing on a pot placed in a pan of water. The experiment had its advantages in two ways—first, the roots were not in stagnant water; secondly, the pan being kept full of water, prevented snails and other vermin from reaching the plant, as it had two narrow escapes from being destroyed previously to using the pan of water. It was watered every morning over the foliage with a rose watering-can, so as to keep the plant clean as well as moist at the roots, and shaded from the hot sun, as it is evident that *Disa* cannot bear the bright sunlight shining upon it without suffering injury.

It was kept in the front of a lateinery with the front sashes open day and night, and only closed when there was any appearance of frost in winter or strong winds.

Although I have not found it as easy to grow as a *Calceolaria*, it may be grown, and successfully, with a little attention bestowed upon it.—*A. EASTWOOD, Gardener to E. Nathan, Esq., Didsbury Lodge, Manchester.*

DISEASED LIME TREES AT PRESTON.

WE insert the following letter from "A LOVER OF TREES," complaining of the diseased condition of a fine avenue at Preston; and as the subject is one of public interest, we have put it into the hands of one of our regular correspondents, whose remarks we append below. At the same time we invite all others having experience in such matters to record it in our pages, as we conceive that trees in a town are too valuable features to be lost without an effort, if by any expedient they can be preserved.

"In Preston we have a beautiful public walk called Avenham Walk, and in it there are two rows of fine Lime trees about 160 years old. These trees are showing symptoms of decay in their upper branches. The walk up to the trunks of the trees is gravel which binds together like cement, and, therefore, prevents the rain from percolating through the soil to the roots. The walk and road round about are also drained, which will prevent the moisture from rising above these drains to the roots of the trees, and to these two causes many parties attribute their premature decay.

"It has been suggested to place six iron boxes round each tree about 6 or 8 feet from the trunk, and at equal distances from each other. These boxes to be 1 foot square, 2 feet deep, with perforated lids, and without bottoms. The gravel walk to incline towards the boxes, so that the rain would enter them and percolate through the soil to the roots. The boxes to be also occasionally filled with liquid manure from the stable tanks.

"The above remedy is suggested with the view of keeping the walk as at present gravelled up to the trunks. Now, will you be so kind as to inform us whether this remedy is worth adopting? if not, what other means must we take to restore health and vigour to these old favourites? By supplying this information you will confer a favour for which thousands will be most grateful.—*A LOVER OF TREES.*"

[It is very difficult to form an opinion that is of much value on a subject like this, without being on the spot, and ascertaining more particulars than those given by the correspondent whose letter is inserted above. So many causes sometimes concur in producing disease, that we are not always right in attributing it to one in particular. The polluted atmosphere of most towns, especially manufacturing ones, is very unfavourable to the well-being of trees; besides which, it is not unfrequently happens that their roots are ruthlessly mutilated or destroyed by one or other of the many underground works every now and then executed in streets and public thoroughfares—such as making sewers, laying water and gas-pipes, and the many works which are thought necessary for the public good. We once knew a

very fine tree that had been for many generations a favourite with the inhabitants of a town, and it was all but killed by a thoughtless excavation for some purpose or other; the material, a good gravel, being carted away, and the hole afterwards filled up with some waste rubbish from a manufactory of chemical substances, which, as the sequel proved, contained very poisonous matter, and ruined the tree. This, however, is not likely to have been the case with those at Preston; but it is not improbable that the long-continued endurance of an unhealthy smoky atmosphere, or some evil of a like nature, may have been in some measure the cause of the mischief. The most likely cause of all, however, is, that the trees are becoming diseased through old age. The Lime tree, though to all appearance naturalised with us at the present day, is thought not to be indigenous, and, consequently, not so long-lived as some trees that are natives. This opinion I merely put forth as one of the reasons that may be given for the decay of the trees in question. And although there are, no doubt, plenty of trees in more favoured situations older and still healthy, the disadvantages those at Preston suffer from are sufficient to account for their more early decay, on the same principle that the bills of mortality relating to manufacturing towns contrast strongly with those of a healthy rural district. Many other reasons for the declining health of the trees might be advanced; but as they all more or less relate to those given, and, probably, are unavoidable or incapable of remedy, it is needless to follow them out further. Let us, therefore, consider what can be done to prevent a disaster that every one would be glad to avoid.

The ingenious suggestion of our correspondent for supplying moisture to the roots is well worthy of attention in other matters as well as in this, and may, perhaps, be attended with benefit when it is carried out. But the Lime tree is one that flourishes better on dry ground than wet, and in more instances than one we have known trees thrive remarkably well, though their roots seemed sealed up from all access of air or water, by the hard-beaten path by which they were overlaid. On the other hand, an aged Lime tree occupying a moderately moist situation, not by any means a stagnant wet one, is falling fast into the condition you mention; all the upper limbs are dead, and the living portion of the tree has been yearly diminishing, until it now consists of only a few subordinate branches at the place where the main limbs broke from the bole. This tree has been in a state of decay for many years, and most likely in two or three years it will succumb. Now, there are none of the evils spoken of above affecting this tree—it is near enough water to obtain all the moisture it requires, and, the surface being grass, it receives all the rain that falls from the heavens. One agent alone, doubtless, operates in both cases:—Old age or infirmity will alike tell in all. That some races are destined to outlive their neighbours is undeniable, but that a time is set for them as well as for the others is also apparent.

To ward off the effects of old age requires more skill than perhaps can be brought to bear on the Preston trees, as it is obvious that disease has set in; and it is unlikely that the authorities of the town would like the walk broken up for the purpose of renovating the roots, by placing them in fresh soil, so as to add some additional vigour to the partially decayed trees. Individual specimens are occasionally benefited by as much of the old earth as can conveniently be moved being taken from off the roots, and replaced with fresh good soil. The stimulus thus afforded is useful for a time, and retards decay for a number of years.

Now, what appears the easiest way of supplying additional food to the trees at Preston, would be to try and feed them at the extremity of their roots on the outsides of the two rows forming the avenue. This is on the supposition that the opening between the rows forms the walk or promenade, and the outer side is more accessible. If this should be the case, the removal of part of the soil, and replacing it by fresh, will be attended with advantage. If on the other hand, hard roads bound the trees on all sides, extending as far as the roots are likely to travel, watering as suggested might be adopted, although we have not much faith in its efficacy; but it can do no harm with old trees, and might do good to young ones. If the ground is very dry, and well drained naturally as well as artificially, then I should say,

By all means adopt the plan suggested, and if possible add more water than merely falls by rain for a few times; but do not apply manure water too liberally, as when this fluid is not used up by the plant it is intended for, it sours the ground, rendering it unfit for healthy vegetation. A little with the water in the growing season will be of benefit. Trees in large towns suffer from many causes, as well as from dryness at the roots, and in some instances they are sadly abused, becoming, as it were, receptacles for nuisances, which, though they endure for a time, they eventually suffer from.

That Lime trees are of quick growth and very accommodating as to position cannot be questioned; but, at the same time, they are still liable to the diseases incident to all vegetable as well as animal life; and we fear no treatment that is at all expedient to adopt will prevent this entirely in the case of the trees in question. We are unwilling to believe the want of water to be the main cause, as the trees must receive on their foliage all that falls in a natural way. Is the gravel forming the walk of a pernicious kind—containing some virulent poison fatal alike to vegetation as well as animal life, as we know some sands to be that are obtained in mining in the west of England? In this case it would be difficult to suggest a remedy; and as it is, we fear it is not an easy matter to effect one. The plan advised by "A LOVER OF TREES" might, however, be tried on a few of the trees, and if found to answer might be extended, as it is not likely to do any harm, and may do good. Assuming the roots to be only accessible by such means, it is certainly worth trying; or a more homely way may be adopted as a temporary trial, which is making a number of holes over the ground with a crowbar, sufficiently deep to reach the soil or nearly so. These holes might be frequently filled with water for a few days until the ground be pretty well wetted, and they might be filled-up with but little injury to the walk. If this were done twice during the growing season it would serve the whole year; and if continued from year to year a partial recovery might take place if the cause is want of moisture. I fear, however, that age and infirmity have something to do with the evil, and if so, all severe measures ought to be avoided. In the meantime see if one side of the tree is not available to work upon, and apply the remedies recommended above. If not, then try water; at the same time examine the various things surrounding the trees, and provide, as far as possible, against nuisances, and the leakage of gas-pipes; and perhaps the public promenade may be retained without being much further impaired for some years. Let us know how it fares with these important ornaments to one of the fairest towns in Lancashire.—J. R.]

THE CASTLE KENNEDY FIG.

UNDER this heading in THE JOURNAL OF HORTICULTURE of the 4th inst. "A CONSTANT READER" makes some remarks about the Fig known in this locality as the Castle Kennedy Fig, which he says he has eaten, and does not remember tasting any of better flavour, and expresses surprise that the Fruit Committee of the Royal Horticultural Society did not report more favourably of it.

"A CONSTANT READER" also suggests that I should show it on some future occasion in larger numbers. This I will be glad to do, the more so as I think it is a different Fig from the one the members of the Fruit Committee somewhat doubtfully suppose it to be. In their report they say, "It appears to be the Large White Genoa." I do not here wish to be understood as finding fault with the Fruit Committee's decision, for every one acquainted with fruit knows how unlike some varieties become when grown in different soils and widely varied circumstances.

I purpose growing the Castle Kennedy Fig and the large White Genoa in the same house next year; and if I can obtain fruit ripe on both at the same time, I will show them together, when the Fruit Committee will have an opportunity of testing their respective merits, if different, and proving whether they are the same or distinct varieties.

Here we grow Figs pretty extensively, but no variety is so acceptable at table as this one; its fine flavour, large size, and showy appearance always arresting attention, and

drawing forth favourable comments. This Fig averages from 5 to 6 ozs. when well grown.

It has frequently occurred to me that if this Fig were better known and more extensively cultivated it would become a general favourite, and find its way to the London Horticultural Exhibitions, and probably displace some of the comparatively humble specimens I have frequently seen taking prizes there.

Of late years almost every other kind of fruit has caught the impulse of the age, and been rapidly improved; but somehow this has not been the case with the Fig. Many think that instead of progressing it has been retrogressing. On account of Figs not being fashionable, some of the finer sorts formerly in cultivation have either altogether disappeared, or are only to be found in out-of-the-way places.

As little has been done for the last half-century in raising new varieties from seed, surely a fine field is now open for some one to devote attention to the improvement of Figs by hybridising. Owing to the formation of the fruit no doubt this is a difficult process, much skill and care being requisite on the part of the operator. A taste, by many considered a very refined one, for this most wholesome of fruits is now springing up in all directions, which is causing more attention to be bestowed not only on its cultivation, but also on the selection of sorts, to be followed in due course by improvements on existing varieties.—ARCHIBALD FOWLER.

NOTES ON GARDENS PUBLIC AND PRIVATE.

NO. 2.—FARNHAM CASTLE.

It is recorded of one of the former occupants of the lordly see of Winchester, that when he died his successor sued his executors for dilapidations on account of his having thrown down part of the old castle in order to fill up the moat. We are fallen, however, in different times now. Under the liberal generosity, refined taste, and admirable management of its present occupant the grounds of Farnham Castle are in so beautiful a state of preservation, that never in the proudest days of this great see, when belted knights and armed retainers filled its halls, could it, to those who delight in tracing the softening effects of our holy religion, have ever appeared so well worthy of admiration as in these more peaceful times when, its moat filled in, platted and decorated, its very keep displaying the skill of modern horticulture, one can dream over its past history, and think how strangely different were the scenes in olden times enacted beneath its walls.

The position of the Castle reminds one more of that of Arundel than of any other I at the present moment recollect. Situated like it on a gentle eminence commanding the town, which seems to lie nestled beneath its walls for protection, it is the very ideal of an old feudal castle. Surrounded by what was an extensive moat, and closed in by some noble Cedars, it will be seen that the amount of pleasure ground cannot be very extensive: while immediately beyond the moat, and separated from it by a goodly wall, is the noble park with its magnificent timber and lovely walks, by the liberality of the Bishop thrown open to the public; but although not extensive, it has been made the most of. When the present Bishop came to the see this moat was partly choked up with rubbish, and partly a kitchen garden. All remnants of both have disappeared. The portion of the keep has been restored; the moat has been laid down with a lovely sward; greenhouses have been built in the upper portion of it, and everything is kept in the most perfect order.

Taking, as is my wont, an early stroll before breakfast, I reached the top of the square keep. Imagine my surprise to find it all laid out in a beautiful geometric garden, sunk about 3 feet below the level of the wall. All around the sides Roses clustered in rich profusion; while in the centre most of our gay bedding plants were (notwithstanding the dryness of the season, which must tell upon such a situation especially), flourishing admirably. In the centre was a high stand, around which was *Saponaria calabrica*; and the remaining beds were arranged in circles round the centre, although of various shapes. Purple King Verbena (as yet unapproached for this purpose), Lobelias, Cupheas, purple Dahlias, Ageratum, Scarlet Geraniums, Christine and Trent-ham Rose Geraniums, Gazanias, yellow Calceolarias, and

various other bedding plants were used and capitally combined; but at the same time, from what I have seen of bedding-out this season, especially at Linton Park under the able management of Mr. Robson, I am inclined to think that greater effect can be produced by fewer things and with more decided colouring. But of this more at some other time.

The beauty of this Castle parterre did not, however, prevent one from enjoying the splendid prospect that meets one's eye from the summit of the keep. In the foreground was the clean and well-ordered town of Farnham, and around it those beautiful Hop grounds for which it is especially famous; while far away the eye rested on the hills of Surrey and the downs of Sussex, affording one of those rich and beautiful scenes for which the South of England is so famous; and in the still early morning, with the bright sunlight of this most lovely summer, the view was especially enchanting.

Opposite the drawing-room window is a geometric grass garden, composed entirely of *Pelargoniums*, and it is remarkable how many tints from both foliage and flowers can be obtained in this class alone. The grass itself is beautifully kept, and mown with the scythe. The Bishop's reply on its being remarked to him that he did not use a lawn-mower was eminently characteristic. "The men like the scythe better." It was no question of comparative merit, but their likings. Amongst the gold-leaved varieties, Mrs. Milford, which was raised here, is largely used. I do not know whether the present season is unfavourable for the growth of such varieties, but I have noticed that not only it, but Golden Fleece, Cloth of Gold, &c., have done badly, the lower leaves scorching up, and the plants making but little progress. Christine, Bijou, Golden Chain, and other well-known varieties make up the various shades required.

The greenhouse, stove, Pine-pits, &c., are situated at the upper end of the moat, somewhat in the rear of the Castle, and, as might well be imagined, from the Bishop's well-known taste for and love of Orchids, are filled with rare and choice species. One house, which was full of flowering plants of various kinds, might well be called the Fuchsia-house. The rafters were covered with fine plants of this very graceful flower, and instead of their being allowed to ramble over the whole of the roof, they were confined to the rafters alone; thus forming a dense mass of foliage and bloom. Fuchsias of the best and newest kinds, florists' varieties, white-corrallad and double, were intermingled with well-grown plants of *Achimenes*, *Gloxinias*, *Gesneras*, *Amaranthus*, &c. Among the *Gesneras* I noticed one, sent out, I believe, by Mr. Dull—refulgens, very beautiful, better than *cinnabarina*, and an admirable plant for table decoration, the play of light on the brilliant crimson hairs, which so thickly stud the plant, making it an object of great interest. I think that oftentimes a great mistake is made in selecting plants for this purpose: the object ought to be to select such as form a striking contrast to the white tablecloth. Thus variegated leaves or light-coloured flowers will not do. Such plants as this or *Colerus Vershafieldii*, or the graceful *Adiantum emarginatum*, are the most suitable.

Nothing could be in finer health than the Orchids, and, of course, all the varieties and species worth growing were here. But I could evidently see that the greatest interest was felt, and naturally too, in some which had been sent to the Bishop by Mr. Tupper, of Albury, who received them from Rio Janeiro, and amongst them were apparently some hitherto unknown species. Can we wonder that in looking on the growing masses of *Oncidiums*, *Zygopetalums*, and *Maxillarias*, something more than mere curiosity should be felt as to what they might prove to be? Amongst other things I particularly noticed were *Grobya Amherstia* and the curious *Fernandezia lunifera*, and, for those who delight in hanging-baskets, what was to me quite a novelty—it may be well-known to others, although the intelligent gardener, Mr. Lawrence, evidently thought not. It is called *Coccoepylum discolor*, in growth not unlike a *Tradescantia*, but bearing a number of bright ultramarine blue berries which continue a long time upon the plant. The Globe Amaranth was also mentioned as a desirable basket flower.

The Pines were in excellent order, both fruiting and succession, the greater portion of them being, as I generally find, Queens, with occasionally a Cayenne.

I had not an opportunity of visiting the kitchen garden, which is about a mile distant from the Castle, but I have no doubt it corresponded with the excellent management of the flower garden. I wish very much that I could convey a more accurate notion of the very beautiful and unique character of this episcopal residence, whose well-tended garden and carefully ordered grounds are, I believe, a correct type of the care and order that reign over that more extended and more important garden, over which for five and thirty years Bishop Sumner has presided, a true chief pastor of the Church of Christ.—D., *Dial*.

AMARANTHUS MELANCHOLICUS—MIMULUS CUPREUS—GOLDEN-LEAVED GERANIUM.

1. CAN *Amaranthus melancholicus* be preserved for next year by being taken up and kept over the winter in the greenhouse? If so, may the plants be put thickly in the pots? and should they be kept dry or moist?

2. *Mimulus cupreus*, after making a brilliant bed for about three weeks, is now with me out of bloom. I understood that it kept the whole season. If I were to cut off the seed-pods, and manure it with tank water, would it blow again?

3. I send leaves of two kinds of golden-leaved *Geraniums*, as you desired some little time ago. The kind marked No. 1 is what I received two years ago from Mr. Scott, of Crewkerne, as Golden Chain, and some experienced gardeners in the neighbourhood say it is true to name, while others say it is not, and that the variety marked No. 2 is the true Golden Chain. Which are correct? And if No. 1 is not Golden Chain, what sort is it? It is not Golden Fleece surely, as that latter has a leaf very like Tom Thumb in shape, and with only the least little speck of green in the centre of the leaf. *Reine d'Or*, which I obtained this year, is a most worthless variety. It has only the narrowest thread of yellow edging. I should add that No. 1 and No. 2 have exactly the same kind of flower, but quite distinct habits of growth. The accounts given by different nurserymen of Golden Fleece and Cloth of Gold are most conflicting. Many of them state that Cloth of Gold has a deep crimson blossom. What I have as Cloth of Gold has a deep scarlet blossom. Golden Fleece has not yet blown with me.—Q. Q.

[1. We do not think you will succeed in keeping plants now in the ground of *Amaranthus melancholicus* over the winter by taking them up and keeping them in a common greenhouse. Though we have not tried it, we presume you would require a house between a hot stove and a cool greenhouse—that is, a temperature averaging from 50° to 60°, and the plants to be kept airy and not too wet, to prevent damping-off. The trouble and risk, in our opinion, would be too great to be advisable, more especially as by sowing seed in a hotbed in February or March the plants may be grown to a good size before planting-out time. We have not succeeded to our mind with it, but the colour is much richer out of doors, and so soft and pleasing, that we mean to try it more largely next year; but we will grow the plants to a good size, and not turn-out until some time in June when the ground is warm.

2. Like most *Mimuluses*, *cupreus* delights in moisture. If you had thinned the beds and removed the seed-pods the plants would have continued to flower. By your proposed plan we expect you will have a fine autumn display.

3. Though you had packed them nicely, yet, unfortunately, the leaves of Nos. 1 and 2 *Geraniums* were mixed, but they are easily separated. The two leaves with the deep irregular yellow margin are exactly the same as small leaves of our Golden Chain, which we have grown ever since it was brought into notice by Mr. Beaton. The other with the thin edging of yellow—but for your statement that the habits are different—we would also pronounce to be Golden Chain, as we could easily pick leaves from the true Golden Chain closely resembling it, though that with the deeper yellow is the better type of the two. We also grew a variety closely resembling the kind with the thin yellow edge, called Golden Edge, much more robust in habit than Golden Chain, and another sort called Golden Circle, of medium strength between Golden Edge and Golden Chain; but none worth keeping, except for mere variety. But for the difference of habit of which you speak, from the leaves alone

we should say you had two varieties of Golden Chain—that with the broad yellow edging being in our opinion the better. As to the yellow No. 3, we are not sure from a mere leaf what it is, but from a little bed of Golden Chain we picked three leaves as like No. 3 as possible, and from a small bed of Cloth of Gold we could have picked a dozen more like it still. We think the yellow tinge without relief is no advantage, just as a pure white Geranium leaf throws a sickly cast of thought over us. Your Cloth of Gold and Golden Fleece are both right. For ourselves we prefer the Golden Chain and Cloth of Gold to all others. We have not yet handled Mrs. Lennox—that is said to beat them all. It is hoped it will not be the miffy thing that Sunset is said to be. We think the different accounts of the colour of the Flower of Cloth of Gold are quite reconcilable. People do not see these matters alike. We have heard ladies say respecting it, "What a lovely rich crimson!" Like yourself, we consider it a dark scarlet. What would you think of the fact of one of the ablest men in our neighbourhood having no perception of colours whatever, only that by a great effort he can make a difference between jet black and brilliant scarlet; and yet he has a great pleasure in visiting flower gardens, having, we are told, a fine eye for form, and outline, though none for colour? We must not, therefore, expect all persons to see colour exactly alike.—R. F.]

SULPHUR AND THE LADYBIRD AS AGENTS IN THE CULTIVATION OF HOPS.

As a communication in a late Number of this Journal, calling attention to the use of sulphur as an antidote to mildew, may have led some parties to suppose that this useful article to the gardening community may not yet have found its way into the Hop gardens, where mildew in one form or other is attended with such serious results, I am induced to make a few observations on the subject—certainly not with a view to put forth any new doctrine on the matter, but simply to inform such as the worthy writer of the article in question what has really been done in the way of counteracting the baneful effects of mildew in the Hop garden, and the various ideas generally entertained on the subject by those whose extensive practical knowledge entitles them to be regarded as authorities.

Gardeners as well as Hop-growers are alike interested in the efficacy of sulphur when it is applied for the destruction of mildew: therefore they will not be the less interested on finding this useful article used in such an extensive way as they have but little idea of in their more limited cultivation. One thing, however, will, I believe, be generally admitted—that to the gardening world we are indebted for the first application of this remedy as a destroyer of insect life of a certain class, and of vegetable life of another; and although the last few years have furnished us with various mixtures, adapted, more or less successfully, for the purposes that sulphur and tobacco were put to before, as well as for destroying a class of insects for which these two useful garden helps were ineffectual, it is questionable whether the utility of sulphur as an agent in assisting good cultivation ever stood higher in public estimation than at the present moment. It is not unlikely that its consumption for that purpose during the present season will be greater than that of any preceding one; and that it may be still more extensively used is not unlikely, from the still increasing good opinion entertained of its utility—not that it is an infallible cure, but that it is an important help is very generally, if not universally, admitted.

The precise time when sulphur was first used as an antidote to "the mould" in Hops, as the mildew is locally termed, I have no means of ascertaining; but it was in very general repute about twelve years ago for that purpose. Unfortunately, soon after that time a report reached the Hop-growers that buyers of Hops objected to its use, and that Hops from which a warrant could not be had that no sulphur had been used in their cultivation could not be received in the market. This imperious edict restricted its use, excepting amongst those sufficiently wealthy to brave the effects arising from it; while, perhaps, some used it unknown to the great Hop-monopolists of the Borough, who

sought to confine them to the old channels of working. At the same time scientific men came forward to prove the absurdity of believing that sulphur used in the early stages of a plant's existence injured it for the purposes for which it was wanted in a more advanced state; but somehow, in their zeal to assist the Hop-grower these men of science went a step too far, and asserted the unfailing efficacy of sulphur as a cure for the mildew in all cases. This having been found not to be the case the remedy fell into some disrepute, until it has during the last few years again been brought forward, and its utility as a preventive in many, but not in all, cases may be now generally acknowledged. At the same time the mode of using sulphur has received due attention, and machinery suitable for applying it has been extensively sought after, and improvements effected to an extent which in the best-constructed apparatus leave as little to be wished for as there is in the best-constructed mowing machine.

The injurious effects of the sulphur on the leaf of the plant having been proved to be only a myth, and the edict forbidding its use either withdrawn or no longer acted upon, while the application of it at a late period of the Hop-growing season is so easily detected, sulphuring now may be said to be confined to the months of June and July, and rarely the first week of August in very late places.

It is not necessary to enter here into all the minutiae of the Hop-sulphuring question; suffice it to say that machinery for dusting the plants with powdered sulphur has undergone many improvements. Some years ago it was administered mixed with water; when a sort of syringe, which eventually grew into the proportions of a moderate-sized fire-engine, was used. More recently sulphur has been applied in a dry state by the aid of fan-blowers, something in the way of a corn-winnowing machine. This contrivance is drawn forward by a horse, the sulphur being blown upwards amongst the foliage of the plant as it passes along. That much of the sulphur falls on the ground cannot be avoided; but its virtues in counteracting the evils of "mould," or mildew, are so generally acknowledged as to induce almost all who have the means to adopt the remedy if the disease makes its appearance.

Some little circumspection is required in the application; and this leads us to the consideration of the second remedy for a Hop complaint mentioned by Mr. Major, page 53—the "ladybird" as he calls it, or what is more generally known here as the "fly golding," an insect encased in a sort of red jacket, which Nature has kindly sent to prey upon the aphid or "Hop fly," which, if unchecked, is an enemy not less fatal to the Hop crop than the mildew.

Now, it not unfrequently happens that the mildew follows an attack of the aphid, and as sulphur has been proved to be hurtful and often fatal to the fly golding or ladybird which preys on the aphid, its application requires consideration before it is made.

That the fly golding is an insect-destroyer has been known, I believe, for nearly a century, and those who benefit by them are naturally unwilling to assist in their destruction even when they invade the home premises, which they invariably do in winter, taking up their quarters in the crevices of walls, or filling up the moulding of a window-frame or other places. Their after-utility is so generally acknowledged as to shield them often from destruction in places where their presence is anything but agreeable.

I believe I am right in saying, that upwards of half a pint of these pretty little insects have been found lurking behind the moulded frame of an ordinary window-shutter. Now, as the fly or mildew as evils to the Hop-grower vary in magnitude according to circumstances, it remains for the grower to determine which is the worst one; and if the aphid be increasing and following the young shoot as it is formed, it behoves him to encourage rather than destroy its natural enemy. If, on the other hand, mildew predominate, a good dusting of sulphur is the remedy and is generally applied; and as no crop is more jealously watched than that of the Hop, a practised hand can see at once what is the matter at the time he examines it, whilst the most far-seeing amongst the whole fraternity have nothing whatever on which to base their judgment as to what may be the ultimate result beyond merely guessing. The close observation made enables them to tell at the

moment which of the two evils just alluded to is or has done most mischief.

No plant that I am acquainted with varies so much in its general growth, and certainly none is so little under the control of the cultivator, his best-directed efforts sometimes resulting in a complete failure, while at other times a good crop rewards very indifferent management. So exceedingly capricious are some of the results of Hop-growing, that the diversity of opinion on the matter is not to be wondered at. It is very fortunate for mankind that the more important cereal crops are more steady and to be depended upon, or serious consequences would follow; and although when we arrive at the full extent of chemical knowledge bearing on cultivation, so as to be able to supply the plant with the material most wanted to insure its doing well, the atmosphere still remains an all-important agent which we have no prospect of ever having any control over. It is, therefore, our duty to protect and encourage all Nature's cures or preventives bearing on the maladies of plants cultivated for our use; consequently, the fly golding, being one, is protected by all those benefited by its presence.

While on this subject I may as well state for the information of those who may be disposed to urge the claims of tobacco as a destroyer of the aphid on the Hop plant, that it has been applied for many years with more or less success, and an extensive grower near here (Linton), annually uses several hundred pounds of it for this purpose. A decoction or infusion mixed with soft soap has been found very beneficial in destroying the aphid; but the fact of its destroying the fly golding also has made some parties timid in using it. One benefit, however, arising from its use, instead of allowing the plant to become quite blighted for the season, is the much healthier condition the plant is in the following year. There is, however, a greater mystery hanging over the well-being of this plant—an attack by the aphid in the following year is an exceedingly rare occurrence. In fact, the oldest Hop-growers declare such has never occurred, while a succession of three or four seasons of mildew is not at all unlikely. Can any of our physiologists account for this?

It is, therefore, very satisfactory that a conviction of the utility of sulphur as a preventive of the mildew has been brought about; and as it is a cheap and easily-applied remedy, hopes are entertained that one of the worst evils Hop-growers have had to contend against will be much mitigated, and to a certain extent placed under control. The subject, however, is one calling for further comment, and I will at a later period of the season again revert to it. In the meantime, for the information of those who read newspaper paragraphs recording the ravages of the fly, or the destruction by mildew, and who may, perhaps, think they are conferring a boon on the Hop-growing community by advising the old-fashioned remedies used in garden structures. I may state that Hop-growers are in no way behind their neighbours in enterprise, either in that way or in the application of manure of various kinds. J. ROBSON.

NECESSITY OF NAMING PLANTS IN PUBLIC GARDENS.

YOUR correspondent, Mr. Keane, shows that even in those splendidly-kept gardens at Kew, the authorities give the public more credit for knowledge of the names of plants and horticultural matters than they deserve. The truth of this I have myself confirmed in my strolls into Battersea, Kensington, and other public gardens this season. In Battersea Park I saw a gentleman taking much interest in the colours of the bedding plants, and the effects they produced. Being desirous of obtaining the name of a plant, in order, as he explained to me, to be able to plant his own garden, he went over the stout iron hurdles to read the name which was written upon a small garden label, such as we generally find in our pots of greenhouse plants, but before he could read it up came a man with a Crimean medal, hat-band, &c., calling out, "Come out there!" The gentleman told him he wanted to ascertain the name of the flower in the bed, and asked, "What is it?" The answer was, "I don't know, and if you don't come out immediately I shall take you into custody. These are my orders, and I shall assuredly carry them out."

Next, in Kensington Gardens, the same kind of park or garden keeper was asked the name of a tree that happened to be an English Yew, likewise the age of the tree. The information I heard him give was, that the oldest Yew tree in this country was not over 150 years old, and that the Yew was first brought to England 150 years ago. The next question was, if Kensington Gardens in the long walk did not contain a good collection of hardy plants? "Yes, the best collection in the world," was the answer. "But why do you not put the names to them, then, so that all persons can see what they are?" "Don't know."

At Kew, on the 8th, I heard several persons ask, "What is the name of that plant? it is very beautiful;" also in the arboretum, "What is that plant?" I thought all the plants at Kew were correctly named. This confirms Mr. Keane's remarks, that the public do not know so much about botany and horticulture as they require to know.—JOSEPH NEWTON, 30, Eastbourne Terrace.

GARDENERS' BENEFIT SOCIETY.

I WAS greatly pleased to see a communication in your Journal from "St. A., Notts," respecting a proposed Gardeners' Society. I merely wish to indorse his opinion of the Gardeners' Benevolent Institution, as I was lately solicited to become a subscriber to it; but on taking the rules into consideration and consulting two or three brethren of the craft, I came to the same conclusion as your correspondent—namely, that it is a most uncertain mode of obtaining a very uncertain benefit (that is, relief in sickness and old age). I shall, therefore, be pleased to hear of the speedy formation of a Society on the plan proposed in a former Number of your paper, and I shall have great pleasure in becoming a permanent subscriber. I will also give my mite towards the necessary expense of formation on being communicated with, and I will use my utmost endeavours to induce my friends to do likewise.—H. B.

THE CULTIVATION OF HEATHS.

BY THE LATE MR. JOSEPH FAIRBAIRN, NURSERIES, CLAPHAM.

I SHALL content myself, in this communication, with treating on what may be termed the elementary parts of cultivation, included under the heads of Selection of Soil, Choice of Plants, and Shifting or Potting the same, as it is my wish, in the general instructions I venture to offer, and which are the result of careful observations, arising from a rather extensive experience, to be as definite as possible, confining myself to a plain, and I hope clear and explicit, demonstration of facts.

First, as to selection of proper soil,—without which every effort, however well directed, and perseveringly followed up, will prove an abortion. The best criterion with which I am acquainted is to obtain the soil from a locality where the wild Heath grows luxuriantly, taking care that it is not dug too deep; the turf certainly not to exceed 4 inches, less rather than more, as, if deeper than that, it is more than probable that the good and nutritious upper soil will become deteriorated by an admixture of inert and mischievous subsoil. The summer months are the right season to procure and store up a heap, which may safely be used after having had a summer and winter's seasoning.

The next matter of importance is the selection of healthy, dwarf-growing, robust plants, taking care to avoid anything like meagre, leggy, stunted plants, which may live for years (if life it may be called), but would only make a specimen calculated to disgust rather than delight the cultivator.

As regards the operation of preparing the soil for potting or shifting, the soil should be cut down from the heap, so as to disarrange it as little as possible, breaking the lumps well with the back of the spade, and afterwards rubbing the soil through the hands, which is far better than sifting, leaving much more of the fibrous decomposing vegetable matter in it; add to this one-fifth of good pure white sand, and well incorporate the two materials together.

Lastly, the operation of potting or shifting. Although not an advocate for what is called the "one-shift system," still, to convert a plant into handsome, well-grown specimen, in a moderately short space of time, recourse must be had

to a liberal shift; and, to avoid anything that may appear indefinite, I would instance what I mean by a liberal shift. I would say, that a young plant in a 60-sized or four-inch pot may prudently be shifted into a 24 or nine-inch pot, taking care that plenty of potsherds are used for drainage; and in the case of larger-sized plants, pieces of sandstone and pebbles may be used. Care should be taken that the soil is well fixed by pressing with the fingers, in the fresh pot, all

round the ball of the plant, so as to make it quite firm and close. After being set away in a cool frame or pit, let them be well watered; all this is much facilitated by placing a convex potsherd over it, and watering with a spout, leaving the water to diffuse itself equally over the whole soil, which is a means of avoiding what frequently occurs from watering with a rose—namely, the surface only becoming moistened, while the ball remains imperviously dry.

Specimen Erica variegata.

Specimen Erica elegant.

I will proceed now to give a list of the best kinds to select for spring, summer, and autumnal flowering:—

SPRING-FLOWERING HEATHS.

Aristata.	Lianæoides.	Vernix.
major.	Neillii.	coccinea.
Andromædæflora.	Siodryana.	Westcottii.
Arbuscula.	Rubra-calyx.	Willmoreana.
Floribunda.	Sanguinea.	Smithiana.
Grandinæa.	Sparsa.	Ovata.
Himalis.	Templeæ.	Persicula rubra.
Lambertiana rosea.	Tenella.	Regerminans.
Linnæana.	Transparens nova.	

SUMMER-FLOWERING (JUNE TO AUGUST) HEATHS.

Aitoniana.	Humeana.	Sprengelii.
turgida.	Infata.	Tortilliflora.
Ampullacea major.	rubra.	Tricolor.
rubra.	Infundibuliformis.	Dunbariana.
elegans.	Iryana.	elegans.
Bandonæana.	Jasminiflora alba.	Wilsoni.
Beaumontiæ.	Jasminoides.	Wilsoni superba.
Bergiana.	Jacksonii.	Wilsoni coronata.
Cavendishiana.	Lawrenceana.	Vasæflora.
Cerinthoides.	McNabiana.	Ventricosa.
stricta.	Massoni.	coccinea.
Clovesiana.	Metulaflora.	minor.
Denticulata moschata.	bicolor.	Bothwelliana.
Depressa.	Mirabilis.	grandiflora.
floribunda.	Mundula.	splendens.
Elegans.	Mutabilis.	hirsuta rosea.
Easoniana.	Murrayana.	alba tincta.
Eximia.	Obbata.	Vernoni superba.
Fastigiata lutescens.	Parmentieri rosea.	Vestita alba.
Ferruginea.	Perspicua nana.	alba grandiflora.
Favoiæ elegans.	Propinqua.	coccinea.
Florida.	Retorta.	rosea.
campanulata.	m jor.	Webbiana.
Hartnellii.	Shannoniana.	Westphalingia.
nana.	Splendens.	

AUTUMN AND WINTER-FLOWERING HEATHS.

Archeriana.	Mammosa.	Verticillata major.
Banksiana purpurea.	major.	Vestita alba var.
Colorans.	Nitida.	Sebania lutea.
superba.	Pieta.	rubra.
blanda.	Princeps.	Gracilis.
Exurgens.	carnea.	cernua.
coccinea.	Pyramidalis.	Rubens.
Incarnata.	Sanguinea.	Carniola.
Bowieana.	Taxifolia.	Ollula.
Longipedunculata.	Vernix ovata.	

From the foregoing sections, whether for exhibition or for general culture, varieties may be selected, that will furnish flowering plants for the whole year.

Heaths like plenty of air; it must be given freely, but carefully; as, from exposure to the dry, arid, cutting winds, plants that are growing freely are apt to get a rustiness that will so disfigure them, that months will elapse before they are free from it. If the plants are in pits or frames, it is well to open the lights on the contrary side to the wind, which will effectually prevent the rush of cutting wind, and thus shelter the plants; at the same time that it is quite efficient for the purposes of ventilation. With respect to the plants grown in the heathery or other houses, it will be well, during the continuance of cold winds, to close the doors to the eastward, and admit air but sparingly from the front sashes, taking care to let down the top lights so as to insure a free circulation of air. When the plants are in full growth, and the weather is of a parching character, it will be necessary to look them over every day, and water freely, taking care that none may be allowed to suffer for want of it, which, at this stage, would prove destructive of the flowering of the plant, if not of its life.—(*Gardeners' Magazine of Botany.*)

ROYAL HORTICULTURAL SOCIETY.

AUGUST 11TH.

FLORAL COMMITTEE.—A meeting of this Committee was held in the Society's gardens at Chiswick. A large number of the members attended to inspect the various bedding-out plants which, by the courtesy of several nurserymen, were sent for probation. A first-class certificate was unanimously awarded to a seedling scarlet Pelargonium brought by Mr. G. Smith, Hornsey Road. This is one of the finest varieties yet raised, producing large massive trusses with bright scarlet salmon-shaded flowers, over which a soft purplish tint is occasionally visible. It will make a first-rate pot plant.

Certificates are not awarded by the Committee to plants grown in the gardens; but their merits are recognised by marks, one denoting commendation; two marks, second-class certificate; three marks, first-class certificate. Scarlet Pelargonium *Roi d'Italie*, presented by Messrs. Low, a light rosy scarlet, received three marks; Pelargonium *Cheshire Hero*, orange scarlet, two marks; Pelargonium *Vulcan*, a darker shade of the same colour from Mr. Wills, two marks. The class of Nosegays, so useful for bedding purposes, and producing great effect from mass of colouring, were carefully examined. *Stella*, the brightest scarlet, so well known for its large compact trusses, had three marks; Lord Palmerston, the same as Dwarf *Crimson Nosegay*, one mark; *Morrinac*, dwarf habit, bright cerise, two marks.

Lobelia Paxtoni (Downie, Laird, & Laing), a very distinct and beautiful variety, white ground, margined with light blue, received three marks; *Lobelia speciosa alba* (Carter), a nearly white variety, two marks; *Tropaeolum* dwarf, King of Tom Thumbs, a very bright scarlet (Carter), one mark.

Verbena General Jackson, two marks; *Verbena Rugby* (Mr. Wills), two marks; *Verbenas Comte Bernard Lechl*, one mark; *Gloire de Curé*, two marks; *Madame Montigny*, two marks. There were many other promising varieties not in condition to be noticed.

Among the annuals *Athanasia annua*, not a new plant, noticed for its bright tufts of yellow flowers, with narrow foliage resembling the *Senecios*, three marks; a very useful annual continuing in flower till very late in the season. *Helianthus argyrophyllus*, a single-flowering Sunflower, with white hoary foliage which makes the plant very conspicuous at a distance, especially when waving in the wind; a very ornamental shrubby plant, one mark. A collection of mixed dwarf *Leptosiphons* from Messrs. Carter were much admired; also *Helipterum Sandfordii*, a plant producing everlasting flowers, which was awarded a first-class certificate at the July meeting.

The *Antirrhinums*, and *Pentstemons*, and *Phloxes* were received so late in the season that they were not in condition for examination. The *Hollyhocks* were scarcely sufficiently in flower, and will be visited again.

The following among the collection were noticed and marked:—*Mrs. Oakes*, 1; *Alice*, 1; *Beauty of Dysart*, 1; *Violette*, 1; *Miss Nightingale*, 1; *Flora Macdonald*, 2; *Lady Dacre*, 1; *Vesper Bell*, 1; *Illuminator*, 2; *Gem of Yellows*, 2; *W. F. Edgar*, 1; *St. Clair*, 1; *Purple Prince*, 2; *Mr. B. Cochrane*, 2; *Golden Fleece*, 1; *Duke's*, 2.

The Committee were pleased to find that varieties among the various classes of scarlet and variegated Pelargoniums which they had on previous occasions examined still maintained their character, and there appeared no reason why any former decisions should be reversed.

Among the Scarlet section and its various shades of colour, *François Chardin*, *Little Major*, *Herald of Spring*, *Adonis*, *Lady Rokeby*, *Lord John Russell*, *Paul l'Abbé*, *Prince of Hesse*, *Spitfire*, *Vivid*, *Monsieur Martin*, *Attraction*, *Sheen Rival* were specially noticed; among the Variegated section, *Flower of Spring*, *Fairy*, *Burning Bush*, *Fontainebleau*, *Mrs. Lennox*, *Koh-i-noor*, *Mary Ellen*, *Meteor*, *Jane*, *Annie*, *Venus*, *Variegated Nosegay*, *Picturatum*, *Argus*, were much admired; and in the Golden Variety section *Mrs. Pollock*, *Sunset*, *Golden Chain*, and *Golden Harkaway*.

There was a unanimous feeling of regret expressed by the Committee present that nothing has been done to induce the Fellows of the Royal Horticultural Society to visit the gardens at Chiswick. Much more information might be acquired by seeing the plants growing and bedded-out than by any description of their merits. Plants specially useful

for certain purposes and for effect could be selected, and the amateur could choose for himself among the endless varieties such as would be suitable for his own purpose and taste. The pyramidal Pear trees alone are worth the journey to the gardens. Most of them are well covered with fruit, and are most admirably trained. The large viney is a model of good cultivation, the Grapes are fast colouring, and the crops very abundant. It would be difficult to find another building in England containing so many varieties of Vines in such excellent condition. These amateurs who complain that they cannot grow fruit in pots would do well to visit the orchard-houses in these gardens. They will find specimens of Peaches, Nectarines, Pears, Plums, Apricots, Apples, Mulberries, and Cherries, all in full bearing, the plants in robust health.

Alas! that the poor Chiswick Gardens should be so despised and forsaken when they still manifest such evident proofs of usefulness, and considering the limited number of hands employed, great merit is due to Mr. Eyles and his assistants that so much is done. Oh! that there might be one small ray of hope left for the Fellows of the Horticultural Society, in the true acceptance of the term, that the ruinous, costly, and most unsatisfactory gardens at South Kensington should be resigned into the hands of Government, or Commissioners, or whoever would kindly take them, and the true legitimate purposes of the Horticultural Society be again resuscitated and brought into full and vigorous action in the old time-honoured gardens, so admirably adapted for carrying out its interesting work.

P.S.—I find in the last Floral Committee's report, the awards made to *Clematis Jackmanii* and *Clematis rubro-vioacea* were omitted. First-class certificates were awarded to both varieties.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The destruction of weeds should always be considered an obligation due to the crops as well as the soil, the efficient performance of which is weakened by delay. *Basil*, to be cut, and also *Marjoram*, and dried just as it is coming into flower. *Carrots*, make a sowing for early spring use on a light, drying piece of ground that is only moderately rich. *Cauliflowers*, if seed was not sown last week, it should now be done, and another sowing should also be made in about a week. In favourable situations the latter will be early enough, no advantage being gained by having the plants very forward before winter. *Celery*, if it has been well supplied with liquid manure, which has been very necessary during such a season of drought as the past, some of the early crops will now be sufficiently advanced for earthing-up. This should be performed on a dry day. Remove all suckers and useless leaves, and tie each plant separately with a piece of matting to prevent the earth from getting into the hearts of the plants. The earthing-up may then be proceeded with in the usual way, taking care to loosen the soil well about the roots of the plants. If they have a good soaking of liquid manure the day previous it will be of great advantage. These remarks will, of course, apply to each crop as it becomes ready for earthing, which should only be done in the case of early and main crops about three weeks before they are required for use. *Dwarf Kidney Beans*, these and *Scarlet Runners* should be kept well gathered, as, if they are allowed to perfect seed, most of the later blossoms will prove abortive. Unless a good supply of rain come shortly watering and surface-stirring must be followed up amongst all the growing crops. *Endive*, make a last sowing for spring use. Continue to transplant from former sowings when the weather is favourable. *Lettuce*, if a sowing of the various sorts to stand the winter was made during the past week, another good sowing should be made in the end of the present one. The former will do for transplanting in the autumn, and the latter may remain in the seed-bed to be transplanted in the spring. *Mushrooms*, collect and dry horse-droppings for making a bed. Keep the droppings spread thinly in a dry airy shed, and turn them frequently, for unless they are well dried it is difficult at this season to prevent the bed heating excessively; and this should be guarded against, as it exhausts the manure, and then there

is only a poor chance of a good crop. *Onions*, keep the main crop well turned about to put them as soon as possible in a condition for storing. *Spinach*, the winter crop to be now sown, if not done already. The Flanders variety is worthy of more general cultivation. Although the sowings above recommended will not admit of much delay, nevertheless, it will be nearly useless to sow without watering and shading. If such cannot be conveniently done, the various sowings may remain over till a change of weather takes place. Continue to water all the crops that will receive actual injury without it.

FLOWER GARDEN.

Look over rock plants, pruning back any that are overgrowing choice ones, in order to give them sufficient time to break again before autumn. Put in cuttings of choice kinds, such as *Saponaria ocymoides*; *Onosma taurica*; *Linaria alpina*; *Phlox nivalis*, *setacea*, *subulata*, *aristata*, *amena*; *Linum flavum*, &c. Plant into borders *Dianthus superbus*, single Wallflowers, Sweet Williams, Canterbury-bells, Mule Pinks, &c. Keep such plants cut back as have a tendency to overgrow Box or other edgings. Tie Dahlias, Sweet Peas, Peg down a few shoots of *Chrysanthemums* for laying in small pots; this is better done after the shoot has turned up at the point. Large evergreens intended for autumn removal should be prepared for the purpose. A trench should now be dug round the tree nearly to the depth of the lowest roots: the advantages attending an early preparation of this kind are manifest. Propagate Hollyhocks by cuttings. Mark good seedlings, digging up all single and semi-double varieties. Attend to the destruction of weeds by hoeing and hand-picking. Tie-up climbers. Dress the edges of beds by pegging or tying. The beds and transplanted things to be liberally supplied with water in dry weather.

FRUIT GARDEN.

It is advisable now to go over the trees and to stop about half the shoots, beginning, of course, with the strongest: for a general stopping at this time would probably be of little further service than to induce the production of a mass of useless spray, whereas stopping the stronger shoots or those which incline to grossness, will divert the sap into the weaker ones, which will be strengthened, while the buds on the shoots that have been stopped will become full and plump without starting into growth. The only effectual method, however, of curing a gross habit of growth when this is the case in ordinary seasons is root-pruning, or keeping the roots within proper limits by means of shallow well-drained borders; and should it be found that the shoots after stopping incline to start into growth it will be advisable, as soon as the fruit is gathered, to open a trench at a moderate distance from the stem of the tree, cutting the strongest roots. This will be of the greatest service in checking growth, and will probably do more towards securing ripe wood than anything else that could be adopted.

GREENHOUSE AND CONSERVATORY.

Plants that are required to bloom late in the autumn and in winter should be repotted and their growth advanced. Chinese Primroses and *Chrysanthemums* are of this class. The latter should be stopped and tied out, so that fine bushes may be produced. These are of sterling value in the greenhouse and conservatory until almost winter, and nothing is so likely to bring them into disrepute as badly-cultivated specimens. Plants for next winter's forcing should now be seen to. Pinks, *Pelargoniums*, and similar plants require to be well established before forcing. The roots should quite fill the pots. Look sharply out for mildew on *Boronia*s, *Gompholobium*s, &c., and where you perceive the slightest speck dust the plants liberally with sulphur. Roses, Lilacs, and other plants for forcing must also be examined, and such as require it should be repotted, afterwards plunging the pots and watering when necessary. Continue to look over climbers, borders, &c. Large specimens which have been placed out of doors to provide room for other plants will soon require houseing. This, however, will depend greatly on the weather.

PITS AND FRAMES.

Some of the first-struck cuttings will now be fit for potting-off; place them in a pit or frame, shade and keep them close until they are rooted, when they should be set out to harden previous to being stored up for winter. Continue to

put in cuttings, more especially the best kinds of bedding *Pelargoniums*, which ought to be struck as soon as possible.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Importance of Clean Water for Labourers' Homes.—We have here a continual struggle with dryness, and are now pretty well at our wit's end to keep things alive. Shaded Celery with laurel boughs; must do so with Cauliflower, or the parlour table must suffer. This hot searching weather, bad as it is for our vegetables, in spite of surface-movings and all the rest of it, is still much worse for the cottagers in many places, who are so destitute of good water as to be obliged to buy what little clear water they can. We are not sorry, from the mass of correspondence sent us on the subject, that the worse than carelessness of building cottages for the working people, and providing no means of pure water for them, is beginning to be looked at as it ought to be. What we have witnessed this summer makes us feel anxious that such true noblemen as our Shaftesburys, and those who may worthily wear the mantle of the late benevolent Lord Herbert of Lea, would try and do something to insure that those who secure the rents of cottage property should be constrained to provide them with the means of health and cleanliness in the shape of pure water. We are well aware that in such a peculiar season ordinary means may break down, and a kind proprietor may be much vexed at witnessing what he cannot remedy. But what are we to think of the selfishness that builds cottage property and takes high rents for it without the slightest provision for water of any kind, leaving the tenant to do the best he can with the pools and puddles that in a moist season will collect by the sides of the highway? The proprietors of this serial have done much to encourage gardening, cleanliness, home-comforts, temperance, and industry amongst the working classes. Let them add to the boon by agitating, in unison with their coadjutors, the importance of a fair allowance of pure water for every cottage home.

Sowed Lettuces for standing the winter, and just a pinch of Cauliflowers. Defer sowing the main lot of the latter until the end of August and the first week or ten days in September. If the plants are large they are apt to bolt and button during the winter. Watered Cabbages almost fit for putting-out, or at least pricking-out. Will sow a few more Cabbages, Savoy's, Red Cabbage, &c., to stand the winter and come in early in the summer, to be planted in spring. After the end of the month and in September prefer sowing Lettuces on a hard surface and merely covering the seed—they will stand the winter all the better. Onions are just coming up. Will sow a few more, chiefly Tripoli and Silver-skinned—the latter makes a nice Onion in spring. Went over Kidney Beans, cleared off all those under protection as first crops, gathered others close for pickling, and removed every pod on the general crop that was swelling hard for seed, as one such pod with the seeds tormented and swelling to ripening-point will exhaust the plant more than a dozen pods fit for parlour or kitchen use. No pod ought ever to be cut for use if it will not break across readily. If it hangs in the breaking process we may rest assured it will never eat crisp and nice. It is best to err on the safe side, and never allow one such to be in the dish. Thinned and regulated Tomatoes, Vegetable Marrows, and Cucumbers. Took up early Potatoes as stated the other week. Took up large Onions, laid over the necks of others with a rake, and would have watered many crops, as Peas, but could not obtain water to do so.

FRUIT GARDEN.

Watered as we could, so as to prevent flagging. Vines, Figs, Peaches, Nectarines. Pricked out runners of Strawberries; watered those potted with dung-water. Find that though rather late the roots are filling the pots fast. Owing to scarcity of water, slightly shaded orchard-houses with a little chalk and water thrown on with the syringe, the water being merely whitened. Was obliged to fill water for small pots of Plums, &c., after having top-dressed them with rough material to keep the moisture in.

These and Cherries have done the best with us in pots this season, though there are some little trees that are densely loaded—too densely loaded—with Nectarines. If we suspected that the next summer would be as dry as the present we would turn all these pot plants out, and give them a little root-pruning as they needed it. When confined to pots there is a good quantity of water wanted, but when planted out they are comparatively independent in a few weeks of dry weather. Commenced nipping a second time shoots of Apple, Pear, &c.; and tying up and thinning the fruit on dwarf Pear trees, as the weight is bringing the branches to the ground as if these were unable to sustain it. The extreme heat is ripening Gooseberries too fast, though still they are very good, and we trust those on the north aspect will remain so for a long time. Gathered Morello Cherries for brandy: netted others, or there would be none for tarts, &c. Fastened-in Figs closely out of doors, and removed or shortened a few leaves, in order that the fruit, though somewhat shaded, should at the same time have a fair amount of sunlight, and thus gain flavour as well as size. Have had some good fruit from pots in orchard-house, and these with those out of doors generally make up the gap between the first and second crop in the Fig-house. Have next to lost a splendid Elton Cherry tree that generally yielded us a dish of fruit every day for six or seven weeks. The tree is old, and we watered as much as we could to help to save it; but some large limbs have gone, and we fear all are going. A young tree of the Florence seems also going, and we believe entirely from dryness at the roots. Singularly enough, notwithstanding the dryness of the season and the heat combined, we have as yet been little troubled with wasps. But of all sorts of flies, moths especially, in the evening, and the myriads of butterflies in a warm sunny day, we never recollect seeing anything like so many. We suspect that the latter will leave their marks on the whole Cabbage tribe in the shape of numberless caterpillars. We notice that already some Brussels Sprouts are pretty well boled with them. Picking them off and syringing with clear lime water are the best remedies. The wasps and flies have done little injury to the fruit as yet, but it is best not to boast too much before we are out of the wood.

ORNAMENTAL DEPARTMENT.

Very much the same as last week. Fretting a little at the continued dryness, as every plant and bed is far too dry for healthy action. However, it is of no use grumbling. If it were only the present we would not grumble about it, as perhaps flower gardens never looked better. Our Scarlet Geraniums are in first-rate condition, and Calceolarias, &c., are as yet fine, though we have some doubts as to their continuance. Much labour has been bestowed on them last week, so that no earth, dirty leaves, dirty foliage, &c., should be seen; and, at last, we suppose we must join with hundreds in saying the many beds as a whole never looked better. At a future time we may mention those combinations of beds that seemed to give the greatest amount of pleasure to the largest numbers, if we may judge from the use of note-books; but for some time we will be too busy to go very much into detail. Meanwhile we may say that we have seen no class better pleased, nor one from whose taste we have received more help in the way of combining, contrasting, shading, &c., than those who have studied colours and their arrangements as drapers, or assistants in their establishments. We once had a somewhat sneering letter sent us because we had recommended those who had a chance to study the arrangement of drapers' windows in London and other large towns. It is good to pick up fresh ideas from this source, and after all the sneering and merriment we consider that much may be learnt in the way of arrangement from these windows. A manufacturer the other day, who had once been a draper, on admiring some beds and the arrangement of colour, exclaimed—"Why, even a draper of first-rate taste could not have done it better!" Of course we took it, as it was seriously meant, to be a very high compliment; and we mention it that our young men may not fear about taking a stare at a draper's window. We are sure, if we had the opportunity of doing so more and reasoning on what we saw, there would be more beauty, taste, fulness and variety in our flower gardens.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers.

POLYSTICHUM AND DAVALLIA LOSING THEIR FRONDS (L. B.).—We have experienced the loss of the fronds of *Polystichum coriaceum*, *Davallia canariensis*, *D. bullata*, *D. dissecta*, *Polypodium appendiculatum*, and were at a loss to account for it. We tried all sorts of schemes, but without any apparent remedy for the evil having been obtained. Our plants are in a cool greenhouse, planted out as in your case, and by comparing the growths of the species above named in a stove fernery adjoining, we came to these conclusions:—That they require less shading than most Ferns, that moisture or dew on the fronds caused them to turn black and die-off, and that they would stand more drought without flagging than any Fern we had, and we had between five and six hundred species. We removed the stagnant moist atmosphere by giving air in the place where the plants were growing, and kept the fronds less shaded than before, and our plants soon commenced to thrive. This year they were doing the same until we resorted to the means named above, and we are happy to say they are now flourishing. *Polystichum coriaceum* and *Davallia bullata*, at the best, seldom succeed in a cool greenhouse; though they do well in a winter minimum of 45°, yet in one often nearly at freezing they remain too long inactive, and have not time to make their growths during the short summer of a cool greenhouse fernery. They should be planted in the warmest and driest part of the fernery, and every available means taken to prevent stagnant air surrounding the plants and dew lodging on the fronds. We have wondered too that *Lygodium scandens* is not more generally cultivated; but many have never had *L. scandens* true, which is a rapid grower, and will soon cover a trellis. We have had it on a rather nearly 20 feet long in one season. *L. palmatum* is often confounded with *L. scandens*, the former of which, although very handsome, is rarely seen above 6 feet in height. All the *Lygodiums* are as elegant as *Gleichenias*, and form beautiful objects on pillars, &c. In fact, without *Lygodiums* climbing up pillars, *Strobilanthes* running on walls, and Mosses growing out of cracks and crevices everywhere, a fernery is robbed of some of its choicest ornaments.—G. A.

AMARYLLIS BELLADONNA CULTURE (W. F.).—Instead of plunging your plants out-doors under a south wall, we would place them under glass in the full influence of the sun to complete their growth, and then gradually reduce the amount of water at the root, and let them have a season of rest by keeping them dry and cool. After that, by introducing into a higher temperature, you will be likely to make them flower. Avoid any excess of water at the roots at any time; and let them have the full blaze of the sun when making their fresh leaves. Under such treatment they should flower with certainty.

UNDERGROUND GRUBS (Beta).—They are the larvae of the daisy long-legs, *Tipula pratensis* or *T. quadristriata*. They are called by many local names, such as "terry trumps" near Cheltenham, but gardeners usually name them "surface grubs" and "leather-jackets." Nitrate of soda (cubic petre) is said to kill them, and lime certainly will; but we examine the soil round the stem of a Cabbage or Lettuce the bark from the stem of which they have eaten, kill the grubs, and insert another plant.

STRAWBERRIES (E. F.).—No variety of Strawberry will be either fine or productive on "a light gravelly soil," unless very great care is taken to mulch the surface throughout the spring and summer, and to have them well supplied with water. We should plant Keen's Seedling and Black Prince.

BOOK ABOUT MOTHS (A Constant Subscriber).—Westwood & Humphrey's "British Moths."

BOOK ON INSECTS (G. Cooke).—Kirby & Spence's "Introduction to Entomology." An edition in one volume was published not long since.

VARIOUS (A Subscriber).—1, we prefer thinning Grapes when they are about the size of a No. 4 shot; but the thinning usually requires repeating. 2, Give a Brugmansia required to flower in July a large shift early, harden it off, plant in rich soil during the middle of June, give plenty of water, and it will bloom until frost injures it. Of course, the same treatment indoors will do. We have Brugmansias in houses dense masses from May to November. Of course, out of doors it will cause less trouble. 3, Azaleas should seldom be pruned back to the old wood, though it is often done successfully. Grafting and inarching are best done with young plants. 4, In syringing, chilled water is best so long as the plants are in a hothouse. 5, Such lists as you mention have been often published in these pages. When we repeat them often readers justly complain that they occupy space that might be filled with new information.

BOOK ON VINE-CULTURE (R. R.).—There is one by Mr. Thomson besides that of Mr. Sanders, and they are each of the same price. Mills "On the Pine Apple" would suit you, but we are not sure about the price; it is not more than 3s.

ORNAMENTAL FENCE (*A Subscriber*).—Peeled oak cord-wood makes a first-class rustic fence, and its peculiar forms may be arranged to suit almost all tastes. An examination of a rustic chair will suggest something of the appearance of oak cord-wood made into a fence; but you can have it placed to suit your own fancy, for rustic work is ornamental in proportion to its rudeness. A fence of this kind covered with *Ayrshire* Roses is one of the finest objects in a garden. The branches of the English Maple (*Acer campestre*), are the best of all wood to form a rustic ornamental fence; but they can rarely be had. The thinnings of larch plantations are most used, and may be made to assume a variety of forms, the commonest of all being upright posts driven into the ground close enough to keep sheep out, with a half pole on top for capping. This is commonly known as the Scotch fence. Any joiner would suggest to you several shapes and put them together in squares, triangles, or diamonds to suit your taste. We cannot undertake to give sketches or projected undertakings, though always happy to criticise those forwarded to us. We are persuaded that few things equal a neat low iron fence which is all but invisible, and still answers the purpose of a hedge. If you wish for something more apparent to the eye, we would recommend larch poles 3 feet 6 inches high to be driven into the ground at 9 inches apart, and at every 12 feet to put in a pole 12 feet long, so as to leave 9 feet out of the ground. From the top of one pole to the top of the next stretch a tarred rope, allowing it to fall in the middle 3 feet from the horizontal, and nail it to the top of each post. We would then plant a climbing Rose and a pillar Rose also, as well as a plant of Honeysuckle at the foot of each post; and put in Sweet Briars, Honeysuckles, climbing Roses, and Clematises along the fence. This would give the finest rustic fence imaginable.—*G. A.*

KEW GARDENS (*Jurensis*).—You might ascertain from Mr. Smith, the curator, whether they have a vacancy.

VINES IN POTS (*Alpha*).—If the wood of your Vines is becoming a little brown, give all the air and as much sunlight as you can, and in a week place them in the front of a south fence and fasten the rods to it, so as to brown them well, giving merely as much water as will prevent flagging. You will need less water if you mulch the pots.

DAYING TOBACCO LEAVES (*Idem*).—Cut the flowers off the tobacco plants, except a few pods for seed. Strip off the large leaves, run a string through them at the thick end, and hang them in a shed 1 inch apart leaf from leaf. When dried, press them very firmly into a box or basket. When heated a little, unpack them and dry them again; then pack them again, and repeat this packing and unpacking until at last you pack and there is no smoking from them. Leaves thus treated and cut up will be capital for fumigation and for cigars too.

GLADIOLUS DISEASE—CHERRY APHIS (*C. E.*).—The disease in *Gladiolus* is very prevalent, and may have been brought on by the three last adverse seasons, which have not been warm enough to ripen the bulbs properly. An eastern aspect is certainly not a good one for anything, but quite good enough for Cherries, which do better as dwarf pyramids or standards than against a wall with any aspect. The black blight, however, is sufficient to cause the barrenness of your trees. It is the Cherry aphid, the worst of the kind to effectually destroy. The best cure is to go over the trees on the first appearance of the pest, and squeeze the points of the shoots or leaves between the finger and thumb, and after that syringing the trees strongly with water heated to 120°. Very strong tobacco water will kill the pest, but it injures the shoots and, therefore, cannot be applied. We have found Page's Blight Composition very serviceable in ridding the trees of this pest, though it is not half so good as the fingers and thumb. It is astonishing how many leaves and branches can be cleared in an hour by the finger-and-thumb system, which, if persisted in, never fails to effect a cure.

LAPAGERIA ROSEA CULTURE (*Subscriber*).—The treatment of this plant has been given over and over again in this Journal. In the first place it requires perfect drainage—extra drainage as for an Orchid, and a compost of fibry loam and sandy peat in equal proportions, with a little leaf mould and silver sand added to and incorporated with the mass. Bits of charcoal not larger than a walnut nut smaller than a hazel nut help to keep the soil open. In the second place it requires plenty of space for its roots, and does best planted out, for it is impatient of checks, such as are occasioned by frequent pottings and rapid transitions of temperature. Thirdly, it likes plenty of light without much sun, and does better in a northern than a southern exposure. Fourthly, it requires watering abundantly, and cannot have too much when growing. Fifthly, it requires a stove heat from March until September, and a cool greenhouse temperature for the remainder of the year. Sixthly, it need not be expected to flower much the first seven years, if a seedling, nor until it attains a good size and is proportionately strong let it be what it may. Lastly, it should not be potted until it gives signs of growth, and then must be placed in a moist and increased temperature. Attention to these rules will cause it to flower.

BOOKS (*G. F.*)—A new edition of "Paxton's Botanical Dictionary" was published in 1849.

GARDEN PLAN (*New Forest*).—We purpose publishing an engraving of your plan next week, with a few notes.

PEACH TREES IN POTS UNDER VINES (*S. W. C.*).—If you, as you state, have Grapes in the same house with your Peaches and Nectarines, we presume trained under the roof as usual, you must not feel surprised at the latter failing, as the trees cannot have sun enough to ripen their shoots. Your potted trees need not be repotted annually, but only top-dressed in October. As your climate is mild and moist there is less ripening power to harden the shoots than under glass. In all climates near the sea coast, with the soft humid air of your county—Cornwall, Peach and Nectarine trees should have brisk fire heat while in bloom, and abundance of air night and day. The same treatment in October to finish ripening the shoots would not be amiss. Surely Camellias in Cornwall would not require any shelter in winter if placed beneath a south wall, and the pots covered with dry fern or other litter. The Rev. Mr. Beaton, near Southampton, has a south wall covered with Camellias, which bloom profusely and have no winter shelter.

COCOA-NUT FIBRE REFUSE FOR POTTING (*Oreoc*).—Used mixed with loam, &c., the mixture should be well pressed and made firm, otherwise the water passes through too easily.

HEATING A GREENHOUSE FOR BREDDING PLANTS (*W. Thornhill*).—From 35° to 45° will be the temperature you will need in winter. We think the pipes heated by gas will do; but you must take the fumes from the burning gas out of the house by letting the pipes end in the open air.

VARIOUS (*An Amateur*).—We cannot recommend nurserymen. If you will buy the "Gardeners' Year-Book," which you can have from our office free by post for fourteen postage stamps, you will there find a list of all the nurserymen in the four divisions of these islands, and you can select for yourself. Set your *Fuchsias* out-of-doors fully exposed to sun and air, take them under cover when frosts commence, a black shed will do for them. Repot early in the spring, using a compost of strong loam one-half, rotted stable-dung one-quarter, and leaf mould one-quarter. The pyramidal form is best; one stem, and the branches cut-in at the time of potting to form a pyramid. Flowers of sulphur dusted over the leaves, and the admission of air freely by night as well as day, should cure the mildew on your Cucumber leaves.

MALE AND FEMALE PARTS OF PLANTS (*A. W. Helfest*).—Neither the dictionary you name nor this Journal professes to teach botany; and the pointing out the different parts of plants is entirely a department of that science. For giving you this information buy "Hensley's Rudiments of Botany," or Macgillivray's edition of Sir J. E. Smith's "Introduction to Botany." In answer to your three queries—most species have the male and female parts of fructification in the same flower, but others have the male flowers and female flowers on different plants, and a third set have male flowers and female flowers on the same plant. Most plants are self-fertilised without the aid of either insects or the gardener. When the pollen of the male part of a flower is ripe, fertilisation is effected by placing it on the female part if that is ripe also.

NAMES OF PLANTS (*M. A. R.*).—*Malva crecea* (Cree's Mallow), a common greenhouse plant, growing about 2 or 2½ feet high. It is not a creeper. (*Oreoc*).—1, *Billardiera heterophylla*; 2, *Lithrum alatum*; 3, *Andromeda polifolia* var. *angustifolia*; 4, *Adiantum formosum*; 5, a form of *Polygonum angulare*; 6, *Alostræria*, some variety of. The poor specimen sent was shrivelled up.

POULTRY, BEE, AND HOUSEHOLD CHRONICLE.

KILLING FOWLS FOR TABLE USE.

LAST week we told our readers the birds they should kill; and we are now disposed to tell them how they should be killed, and how prepared for that which a talented French writer on poultry calls "the sacrifice."

There is certainly an indisposition to eat butcher's meat in hot weather. Fish is at a discount, unless it be in the shape of that most delicious of all unwholesome food, a lobster salad, or the most treacherous of plain boiled, a crab. Something must be eaten in families, and those who read *THE JOURNAL OF HORTICULTURE* of last week (their name is Legion), look wistfully at certain dwellers in the farm-yard which do not seem to promise excellence; and they speak in favour of roasted fowl and lettuce. Little Sarah loves every living thing, and rather prefers the "naturals" and the "unfortunates," the chickens that persist in trying to look behind them, and have what the country people call the "gids;" that one whose right foot turns the wrong way; and the poor little hunchback that puts her in mind of "Master Walter." None of these may be killed. Pa has twelve that may not be killed. Ma has just eighteen pullets she must have for winter layers. One says the last were so hard and stringy he could not eat them, and the last but one was actually tainted, though it had been dead but forty-eight hours. We think we said all we had to say of the unfortunates last week. The week before we wrote of securing eggs, and now will speak of killing.

The ordinary method is to slip into the hen-house at night, to catch two chickens, to cut their throats, to tie their legs with a piece of list, and to hang them up feathers and all. When they are wanted forty-eight hours afterwards, cook says, "She never see such weather; they're green already!"

If the fowls are to be eaten on Thursday, let them be caught on Monday evening, and then shut up in a basket, absolutely without food or water till the next morning. Being quite empty, they must be killed, not by cutting the throat, but by breaking their necks. Take hold of the tips of the end or flight-feathers of the wings, and the lower part of the thighs and knees with the left hand. Take hold of the head of the fowl in the right hand, turn it (the head) upwards in the hand, but simultaneously pull up with the left hand, and press down with the right. Izaak Walton said, "Impale the frog as if you loved him;" and Talleyrand said, "No zeal in anything, it is always getting into trouble." No zeal, no strength, and very little effort is required. Press downwards with the right hand till there is a trifling jerk—it is the dislocation of the neck. Death ensues in a few minutes. If there is any doubt it can be easily solved by feeling the back of the bird's head, there will be found an "ugly gap" between the head and the neck. When a fowl is bled to death it is very white, but it is often dry; when

it is killed by dislocation of the neck it is juicy. As soon as the bird is dead, indeed I should say *directly* it is dead, it should be picked. The large feathers, the wings and tail, should be pulled first. The reason why they should be picked is that the fowl then gets cold; it is for the same cause essential that they should be killed early in the morning or in the evening; the latter is preferable. Even in hot weather the fowl is spoiled nine times out of ten by the fermentation of the food, or the decomposition of the water that was in the body at the time of death. The bird fasted and killed as we have described may be drawn and trussed for the spit some hours before it is wanted, and spite of hot weather it will be sweet, tender, and juicy.

POULTRY SHOW AT STOWMARKET.

On the 30th and 31st ult. the first Exhibition of a Society just started at Stowmarket, the object of which is to hold a show of poultry every year, took place. It was announced as the "Eastern Counties Grand Poultry and Horticultural Show,"—a somewhat high-sounding title. The Exhibition was held on the grounds of Abbott's Hall, the residence of Wm. Prentice, Esq., by whom they were kindly offered to the Committee; and they are admirably suited to the purpose to which they were put. The time of year is very much against a good Show, the birds being just now in full moult, and this tended to keep down the number of entries. Nevertheless the Show, even as regarded the number of entries, which was nearly ninety, or about 250 birds, was good; and as to the quality of the birds, better could not have been expected. This first meeting may, therefore, be pronounced an unequivocal success. The arrangements of the Committee and their Honorary Secretaries, Messrs. Hanson and A. L. Simpson, were excellent, the pens being arranged in two rows, one above the other all round the tent, while the spaces between them were filled with evergreens, and flags were suspended from the top.

There was no competition for the prizes offered for *Spanish* fowls. The show of Coloured *Dorkings* consisted of five pens, several of which were first-class birds; this is evident, from the fact that the Judges after awarding the two prizes considered a third pen worthy of high commendation, and also commended a fourth. The first-prize birds (Mr. Lingwood's) were beautiful specimens of the breed, and have taken prizes at the Crystal Palace, Birmingham, and other places. The cock in the second-prize pen (Mr. H. Payne's), was well worthy of special distinction: the characteristics of the *Dorking*—short on the legs and broad in the breast—were fully developed. There was really no competition in the White *Dorking* class; the only two pens shown belonged to Mr. H. Lingwood, of Needham Market, who is so celebrated in this breed. There were six pens of *Cochin-Chinas*, on this occasion divided into two classes—Coloured and White, and Partridge. The first-prize cock in the former class, which, although termed Coloured and White, consisted entirely of Buff, looked a giant among fowls. The second prize was taken by a cockerel and two pullets under five months old, and very fine birds of their age they were. The entries in Partridge *Cochins* were only two; but the first prize, belonging to the Rev. H. Curry, are a very celebrated lot. In the *Dorking* chicken class Mr. Jas. Frost, of Parham, took both prizes with some of his celebrated stock; and Mr. H. Payne's, which are chickens of the birds which took the second prize in Class 2, were highly commended. In Black-breasted *Game* there were nine exhibitors. Mr. Matthew, of Chilton Hall, Stowmarket, whose *Game* stock is very celebrated, taking both first and second prizes. An extra prize was awarded to Mr. James Goodwin, of Hollesley; Mr. Reason Goodwyn, of Woodbridge, receiving a high commendation. The whole class was worthy of commendation. Mr. Matthew's cocks were decidedly superior to the others in height, in the cleanliness of their heads and squareness of their body. It must have been a difficult matter, however, to say which was the better of the two prize cocks. There were only three exhibitions of Duckwing *Game*, but the Judges thought them all worthy of commendation. Mr. S. Matthew was the only exhibitor in the White and Pile *Game*. The *Game* chicken class had five entries, of which three were Mr. S. Matthew's, and with them he took first and second prizes,

and his third pen was highly commended. In the class for Any variety not included in other classes, there were eight pens, and both prizes were taken by Mr. Samuel Waters, of Ipswich, with French birds of the *Crève Cœur* breed—black birds, with crests. Mrs. S. Nunn, of Rushall, showed some Africans in this class—white fowls whose plumage more resembles hair than feathers: these were highly commended. Mr. J. Oxer, of Sheldall, had a couple of pens of capital half-bred Spanish fowls. The other fowls shown in this class were Gold and Silver-pencilled Hamburgs. The first prize in *Game Bantams* was taken by Mr. J. Frost, they were of the Black-breasted sort. Mr. R. Goodwyn took the second prize, and he also showed the chickens of these birds. The other sorts of Bantams were worthy of notice: the first-prize pen belonging to Mr. Riley, of Onclhouse, were Gold-faced; the second, Mr. H. A. Oakes's, were Rumpless or *tablets*.

The *Ducks* were good in all classes. The White *Aylesburys* shown by Mrs. Seamons, Hartwell, Aylesbury, who took both prizes, were really wonderful birds, and one would have thought it scarcely possible that they could have arrived at such a size in four and five months.

The *Geese*, as a class, were very fine; Mr. Sparling's, which took the first prize, were only twelve weeks old. The first prize *Turkeys* (Mr. J. Bird, of Great Finborough), were beauties.

The *Pigeons* were a very large and good class, the two prizes being taken by Mr. D. H. Feltham, of Kentish Town, London, with Black Carriers. Mr. Feltham also exhibited a beautiful pair of Dun Carriers not for competition. The following is the prize list:—

DORKINGS (Coloured).—First, H. Lingwood, Needham Market. Second, H. Payne, Stowmarket. Highly Commended, J. Frost, Commended, J. Smith.

DORKINGS (White).—First and Second, H. Lingwood. **CHICKENS**.—First and Second, J. Frost, Parham. Highly Commended, H. Payne; J. Smith. Commended, J. O. Dixon.

COCHIN-CHINA (Coloured and White).—First, Rev. G. Gilbert, Claxham, near Norwich. Second, Mr. C. T. Bishop, Lenton.

COCHIN-CHINA (Partridge).—First, Rev. H. Curry, Bosmere Hall. Second, Rev. G. Gilbert.

GAME Black-breasted and other Reds.—First and Second, S. Matthew, Stowmarket. Third, J. Goodwin, Hollesley. Highly Commended, R. Goodwyn. Commended, J. R. Kersey.

GAME (Duckwings and other Greys and Blues).—First, S. Matthew. Second, R. Goodwyn. Commended, J. Goodwin.

GAME (White Fles, Blacks and Brassy-winged).—Prize, S. Matthew.

CHICKENS.—First, Second, and Highly Commended, S. Matthew.

HAMBURG (Golden-spangled).—Prize, Mrs. A. Patten, Maldon.

HAMBURG (Silver-spangled).—Prize, T. Twose, Haslemere.

ANY OTHER VARIETY.—First and Second, S. Waters, Ipswich (*Crève Cœur*). Highly Commended, J. Oxer; Mrs. S. Nunn.

BANTAMS (Game).—First, J. Frost. Second, R. Goodwyn, Woodbridge.

BANTAMS (Any variety).—First, J. Riley, Onclhouse. Second, H. A. Oakes, Buxhall.

DUCKS (White *Aylesbury*).—First and Second, Mrs. M. Seamons, Hartwell, Aylesbury. Commended, C. Tyrell, Hargrave.

WHITE DUCKS (Any variety).—Prize, H. A. Oakes.

DUCKS (Rouen).—First with both. Second, J. R. Kersey.

DUCKS (Mixed breed).—First, H. Wicks, Bawley Mills. Second, J. Oxer.

GOOSE.—First, A. Sparling. Second, W. Green. Commended, W. L. Webb.

TURKEYS.—First and Second, J. Bird, Finborough.

PIGEONS.—First and Second, D. H. Feltham, London. Highly Commended, H. A. Oakes. Commended, R. Partridge, A. Sparling.

RABBITS.—Prize, G. Gudgeon, Stowmarket. **BUCK**.—Prize, A. J. Alexander, Ipswich.

SWEEPSTAKES.—*Cochin-China* Cock.—Prize, Rev. H. Curry. *Dorking* Cock.—First, H. Lingwood. Second, Mrs. M. Seamons.

The Judges were the Rev. Thos. Lyon, Fellowes, Beighton Rectory, Norfolk, and the Rev. Morton Shaw, of Roughton Rectory.—(*Suffolk Chronicle*.)

HEDGEHOGS AND SNAKES DESTROYING CHICKENS.—I see in your Journal of the 11th a confirmation of the fact of hedgehogs destroying chickens; and to me this is of importance, as I have just had turned loose in my yard three young hedgehogs and an old one, and I shall now order them to be caught again. My object for turning them loose was to drive away the mice and rats. I knew that snakes and blindworms will kill chickens. I had a very choice lot of these, which I sent to a splendid walk, as I thought, it being in the midst of a large coppice; but I received word that six out of thirteen were gone in one day. I set out determined to watch; and towards twelve o'clock, the sun being very hot, I went into the shade behind some trees. The hen and brood were near an old wood pile, when all at once the hen and chickens fled in all directions. I jumped

to my feet and saw two snakes, one of which I caught: it is about 12 inches long. They were making directly for the chickens with their heads about 4 inches from the ground. POULTRY-FANCIER.

GOSLINGS WASTING AWAY.

A FEW weeks ago I purchased twenty-four Geese, fourteen of which have since died. These I found to be infested with insects (lice, I presume), as per enclosed specimens. Never having had any similarly affected, I am at a loss to account for them, and am desirous to know how to get rid of them; also, the after-treatment to strengthen the birds. They seem daily to grow weaker and less disposed to take either food or exercise; in fact they become quite torpid, and at last die from apparent exhaustion, complete skeletons.—J. G.

[All Geese are subject to lice. They are confined to no age, condition, or sex. They seem to have been made for them. Being perfectly flat, they bestow themselves carefully from two feathers and the water has no effect; but if it should penetrate they take refuge in the down. If the down should get damp, instinct prompts the bird to leave the water directly if possible. If you were to go to Leaden-hall at Michaelmas and look at the best, largest, and fattest Geese, and if you were to examine them attentively you would find, that although they were plucked some lice remained sheltered in the wings and those parts that were still feathered. There is no Goose without them. They do not, therefore, cause the death of your goslings. If you bought in your immediate neighbourhood, either you have been imposed upon or your feeding has been bad. If you bought in London there is no knowing where they were bred. Goslings come in flocks from France, Holland, and Belgium. Of our own countrymen, Scotland and Ireland help us. The history of Geese is a history indeed. Stratford in Essex had formerly the monopoly of feeding. Thither all the flocks of Geese wended. From the beginning of July till the end of August all the roads leading to Stratford were full of Geese, tended by one man who kept all in order and stayed any wandering propensities on the part of any of his charge by catching the offender by the leg, not with his hands, be it understood, but by means of his crook. A long, very long rod, had a stout wire at the end, twisted something like a crook, but more elaborately. It was widely open at the mouth, but narrower at the end, and held the leg so fast that the Goose gave in and laid down. "*Nous avons changé tout cela.*" Where there are no commons there will be few Geese bred, and commons are fast disappearing throughout England. The consumption of oats in Stratford during the months of August and September was incredible to a stranger, and the slaughter the same. These are, however, the records of past ages and have little to do with our present question.

If the Geese were in good condition when you bought them, ascertain how they had been fed and feed the same. If in doubt, shut them in a pigsty, fill a trough with growing sods of grass half full; on them put some gravel, then a layer of oats, and then fill by pouring water gently in one corner till it is full. Your Geese will feed and thrive.]

FOUL BROOD NOT AN ARTIFICIAL DISEASE

It is with regret that I perceive so high an authority among bee-keepers as my friend Mr. Taylor pronouncing the disease which has recently devastated my apiary to be "an entirely artificial one"—regret, not on my own account (for to me personally it is of no importance), but for the sake of others, since, if such a mistaken notion obtain currency, farewell at once to all the benefits which I had hoped might have arisen from giving publicity to my misfortune, whilst the cause of progress amongst English bee-keepers will receive a check which may long keep them immeasurably behind their continental and American contemporaries.

With the view, therefore, of removing this false impression, I will describe two instances which have come under my observation in which foul brood has manifested itself in hives managed in the usual way.

Last spring I received a lot of comb procured for me in the county of Wilts through the kindness of a brother apiarian. Among these were some which had died of foul brood, that I now know came from a colony, but which there is no reason to believe had been in any way interfered with.

The other case came more immediately under my own observation, and may be deemed perfectly conclusive on this point. Last autumn I turned up a common straw hive belonging to an "old dame" who resides at about three miles distance. There was some honey, but very few bees, and I confidently pronounced the queen to be defunct. In this, however, I was mistaken. When the bees were afterwards expelled by driving a living queen was found, but the colony was nearly extinct from the effects of foul brood. This I now know to have been the case, although at the time the affair appeared perfectly inexplicable, and an inspection of the combs did not then enlighten me—now I should recognise them at a glance as having belonged to a foul-breeding stock.—A DEVONSHIRE BEE-KEEPER.

FURTHER REMARKS ON EXPERIMENTAL BEE-MANAGEMENT.

I CANNOT help making a few remarks on the opinions and theories put forward by some of the writers in No. 123 of your Journal. I fully admit that Mr. Lowe lays down the general principles of apiculture correctly and well; but I cannot perceive that he has solved the mystery of the origin of Mr. Woodbury's foul brood. I do not mean its introduction into his apiary—Mr. Woodbury himself has told us how that occurred—I mean its original cause. I have no theory of my own on the subject, and shall be ready to believe that it arises from too much experimenting, or from anything else, when good evidence of the fact is forthcoming; but I cannot think of leaping to such a conclusion. I know that experimenting may be carried too far; what cannot? A merely experimental apiary can never be a thoroughly prosperous one; but it does not, therefore, follow that it will become diseased. It will become weak from the constant interruption of breeding, and paucity of numbers will cause poverty of stores; but are weak hives more liable to disease, properly so called, than strong ones? I think not. I have had more or less of chilled brood under various circumstances, but never knew it to become corrupted in the hive, nor do I think that it ever would, so long as there were bees enough to perform the usual routine duties. Even if it did, I do not think that it would be so virulently contagious as this foul brood appears to be. Mr. Woodbury's opinion—nay, assertion, that it was introduced to his apiary in purchased combs, no doubt gives the immediate cause in his case. I expect that he will conquer the enemy without departing from his own line of tactics, and go on his way rejoicing; but I fear that he will have to leave the abstract cause of foul brood as much a mystery as it now is.

Mr. Lowe is right in maintaining that forced swarms should only be made in "accordance with the natural instincts and habits of bees, and with a due regard to time, circumstances, and condition." When so made, the operation is not, as Colonel Newman expresses it, "fighting against Nature;" but the exercise of man's undoubted right to make Nature subservient to his wants and wishes. Dominion was given to him over the brute creation, in its entirety, bees being no exception. He cannot change the operations of nature; but he may and does modify and adapt them to his requirements. The sheep's wool would, no doubt, fall off naturally without the assistance of shears, but not in a convenient form for our cloth-makers. The cow would give spontaneously as much milk as was necessary for the sustenance of her calf; but the farmer finds it to his advantage to manage these matters in his own way. Nor does it appear that the cow is in any way injured by prolonging her natural period of giving milk, or the sheep by the premature loss of its fleece; though I dare say there were antique men who protested against both these modifications of nature when first introduced, using much the same arguments as their representatives of the present day use against the rational management of bees.

That "driving" does not always succeed is scarcely a good argument against its general usefulness. No great

amount of patience is required to keep tapping for fifteen or twenty minutes, and this period, though not always sufficient, will often be so.

It is to be regretted that "Jonas Jackson" has not told us more in detail what steps are necessary to secure the co-operation of our bees. In what language are we to address them? Their own? I for one understand it not. Will plain English do? May the German or Frenchman speak to them in his own idiom? If so, bees are pretty good linguists. Suppose I want to make my Ligurians "a speech," who will translate it for me? Their nationality has been disputed, and if it were settled I should be no better off, for I understand neither Swiss nor Italian. It is true that the horse and the dog understand certain words and phrases; but much care is bestowed on their early training to make them know that certain sounds convey certain ideas; and I do not clearly see that a similar course is at all practicable with bees. Virgil and the rest of antiquity may be excused for their inaccuracy as naturalists, but just fancy a nineteenth-century man

"——— heir of all the ages
In the foremost ranks of time,"

mounted on a stump in his garden, gravely haranguing the bees about his domestic felicities or calamities!—JOHN P. EDWARDS, *Shirleywick, near Stafford.*

WOODEN HIVES.

THE materials of which hives are made, as well as their construction, have an important influence over the quantity and quality of honey, and in facilitating the working of experiments.

Now, wood and straw are the most common hive-materials in this country, and the only kinds I ever used for general purposes; and I do not intend to raise an argument for the one, nor objections to the other, but simply to state the experience I have had of both, but without speaking of their construction.

When I first adopted wooden hives, it was from not being able to obtain a sufficient quantity of a peculiar make of straw hives which I had ordered. The first winter I had them I had an equal number—viz., five of each, and I met with every discouragement from my neighbouring bee-keepers. Every one had a different reason to demonstrate that I would not have bees long; but not one of the objectors could explain to me the cause that would destroy the bees. So I was left alone in my undertaking.

I was not ignorant about the nature of wood, and I took care that no external damp whatever, unless that of the atmosphere, could touch the hives.

The alighting-board I made moveable, with a space between the hive and it, so that the rain could not get near the hive. I set the hives all in one direction and equally well protected, so that they would have a fair chance for proving which should do best.

It is a singular fact that I have never had a single death of a swarm from disease or other cause in my wooden hives; but it was very different with the straw hives—I lost every one of them in about eighteen months. The reason of this was abortive brood. The cause of the abortive brood I attribute to the straw hives being a little warmer than the wooden hives, and the very changeable weather here in spring; consequently, when a few warm days occur, where the queen is prolific, she spreads her brood more than the bees are able to attend to if the weather turns colder, as it often does. When this takes place the loss of the hive is certain, unless some of the combs are removed—not only those that are affected but also those adjoining, till no more are left than the bees are able to cover. This restricts them from breeding more than they are able to attend to, until the weather becomes warmer and encourages their forwardness, when they continue to do well.

This removing of combs I have done often and have never failed. I also make it a rule once or twice a-week to smell my hives to know whether they are free from foul brood, which is easily detected by the strong effluvia, but I have never been troubled with it in my wooden hives. Some people make it a rule to cut out only those portions that have foul brood in them; but this will not be effectual, because

there is always scattered brood which is not easily seen, so that the bees are kept scattered and are never able to keep up a uniform degree of heat. Nay, it is better to turn the bees out of the hive altogether, substituting a new and clean hive, because it is doubtful if ever they thrive in a hive that has been once diseased. The infection seems to adhere to the hive, so that it may be termed the "bee plague."

I would recommend as better than an empty hive—seeing that it is mostly in spring that this malady rages—a hive with clean combs; but if this cannot be obtained, as bees will not thrive if deprived of combs in spring, I recommend as an excellent substitute the new wax sheets, which can be had at a trifling expense, and which would enable the bees to go to work at once, and by a little feeding they would soon do well.—A LANARKSHIRE BEE-KEEPER.

WEAK AND UNHEALTHY HIVES—FOUL BROOD.

SINCE the date of my last communication, which appeared in the Number of the 4th August, and which took notice only of Mr. Woodbury's first article on "A Dwindling Apiary" in the Number of July 21st, we have been favoured with two or three additional contributions by him on the same subject, explaining the nature of the evils by which his apiary has been well-nigh ruined, the means by which these evils were brought about, and the remedies employed to extirpate them.

I shall make a few remarks on these three points. Mr. Woodbury, in reply to "B. B." in last Number, describes foul brood to be "a disease which attacks the young larvæ in their various stages of development. At first only a few die, but as these putrefy in their cells the infection spreads until very few bees arrive at maturity, and the stock dwindles and ultimately perishes."

Now I have no desire to find fault with Mr. Woodbury for so describing this evil. He is following in the footsteps of not a few apian writers in so doing, and besides, it is a subject of which, as he himself says, he has hitherto had little or no practical acquaintance. But in this, as in a great many other matters, writers are apt to perpetuate errors by accepting for truths the mere dicta of others without due reflection and consideration. If foul brood be a disease, I should like to know by what it is caused. Are the ova as deposited by the queen tainted with the germ of some malignant epidemic, or is the malady induced by the nursing of infected adult bees? How does it originate? I know of no writer who has, in my estimation, satisfactorily accounted for the presence of foul brood in a hive on the supposition of its being a disease. Mere surmises and conjectures we have in abundance, but nothing more; and the so-called malady is in its origin and character left completely in *dubio*. Mr. Woodbury promises a digest of the views of some of the more reliable American and German authorities on the subject; but while I shall always be glad to peruse any article from the pen of so accomplished and able an apian writer as Mr. Woodbury, yet I know of no subject treated on, both by ancient and some modern writers, so full of errors as that of the diseases of bees. My general practice, indeed, in reading any work on the bee, is to pass over with a mere cursory glance the chapter so designated. The fact is, the ailments of bees are few and simple, and such as are induced by famine and filth, by confinement and spurious and insufficient food. I am not disposed, therefore, to view the presence of foul brood in a hive as a disease, properly so-called, at all. If I am right in accounting for its origin, it can no more be called a disease than if we were to snatch the unhatched eggs from a domestic fowl during the period of incubation, expose them to the chill of a frosty night, and then ascribe the death and consequent decay of the embryo chicks to a natural disease produced by some unaccountable cause. If it is to be termed a disease at all, let it be described as Mr. H. Taylor described it in last Number—an entirely "artificial one." Abortive brood, however, properly speaking, can never be classed under the category of bee maladies.

Let me here anticipate any objections which may be urged to the evils in question being produced only artificially. In

my communication, be it remembered, I adduced only a few of the causes which produce foul brood, and which I thought strictly applicable to the case before me; but I have witnessed the same evils caused without the intervention of a single artificial process; and while I could create or originate abortive brood in any hive at pleasure by a few manipulations, I have also seen it produced in some instances from purely natural causes and without any interference on my part at all. Weather influences alone may give rise to it. Let me illustrate this. Some few years ago I had a very vigorous colony domiciled in an observatory or unicombe-hive. The weather (it was in autumn), was extremely warm. The queen had extended her laying down nearly to the floor-board. A sudden and violent transition of the temperature occurred, however: cold frosty nights forced the bees upwards in the hive; the brood in all stages were neglected, and thus the evil was generated in this hive simply by weather influences alone, rendering the part of the comb so affected permanently and entirely useless. The same state of matters may be produced likewise in straw hives, in cases where a populous swarm may have a large surface of brood-comb with little honey, and be overtaken in such a condition by a long continuance of cold adverse weather. In such circumstances the bees diminish in numbers with astonishing rapidity; the necessary warmth, attention, and nursing being withdrawn, the brood are neglected, and abortions to a large extent often occur. In early spring, too, in sparsely populated hives, through the operation of somewhat similar causes, I have witnessed these evils originated on a limited scale.

Notwithstanding all this, however, foul brood is an exceptional occurrence, and rarely met with in ordinary circumstances. It is only in the hands of the experimentalist that we find its presence generally manifested, and for this reason—that when bees are domiciled in suitable hives, and when left, as I stated before to Mr. Woodbury, to themselves, and allowed to follow unrestrained the impulses and instincts of their nature, such disorders will seldom arise. Seldom do bees err in their instinctive powers of adopting suitable means for desired ends, of so regulating and adjusting their whole internal economy as to provide for the exigencies and conform to the requirements of the occasion, and thus prevent the bringing about a state of matters which is productive of such evil consequences as foul brood. I have often contemplated with the profoundest admiration the wonderful instinctive foresight of the bee in thus providing for future contingencies and wants, and that no less wonderful sagacity which guides the queen in the interesting business of oviposition, accommodating herself, so to speak, to the particular state or condition in which she may be placed, withholding or meting out from the almost inexhaustible resources of her ovary, both as to sex and numbers according to circumstances and season. In all this there is much to admire; and the contemplative student will involuntarily turn his thoughts beyond the blue serene which o'eranopies this busy world of ours, and exclaim, "How manifold are Thy works, O Lord! In wisdom hast Thou made them all."

I have thus shortly alluded to the nature and causes of the evils complained of—foul brood, and now let me make a few remarks as to the remedies employed by Mr. Woodbury for extirpating them.

In following Mr. Woodbury in the various processes resorted to for this purpose, I cannot help repeating my conviction, notwithstanding the importation of polluted combs from other apiarians, that the real evils with which he has had to contend have been principally brought about by his own doings and manipulations. When I took it upon me to tender my opinions to Mr. Woodbury, and to attribute the whole of the mischief complained of to experimental operations allowing the brood to get chilled, I confess I was not then aware of the precise method adopted by him for the transference of bees and combs from one hive to another; but as I perused the account of the several operations as detailed at page 78, with the prime swarms purchased in the country, can I fail to wonder—can any one fail in wondering—that the consequences resulting therefrom would be aught else than what we find subsequently described at page 97—namely, the re-appearance of the evils in these fresh-imported combs? Let me restate one of these pro-

ceedings. A prime swarm is purchased in the country several miles distant from Exeter. The bees are then driven, say of an afternoon, and put into a hive furnished with empty combs. This is all well; but what is done with the hive itself, full to overflowing, no doubt, with brood in all stages, from the newly-laid egg and hatched grub up to the full-grown pupa? It is left empty and tenantless! In this state it is brought home to Exeter, and stowed into a corner of the kitchen for the night; and next morning, still destitute of bees, the combs are cut out, fitted and fastened into frames, and then—only then—after a dozen hours interval, it may be, and all the manipulating work besides, are the intended bees introduced to these combs full of chilled and neglected brood. Can it be wondered at that the tender little grubs (not to speak of those more advanced and sealed), requiring so much attention, care, and warmth from the bees, should give way, and that in such circumstances foul and abortive brood would not as a consequence follow? Mr. Woodbury may feel that I express myself too strongly; but such a mode of proceeding is so contrary to my own practice, and what I believed to be the general practice of apiarians in such circumstances, that I cannot help recording my utter surprise at the whole matter. It may be that there is some error in the narrative or that I have misinterpreted it; for though I admit that the more advanced pupæ can remain for a considerable time uninjured in such circumstances, I can never allow that the tender larvæ will not suffer from such a lengthened and protracted exposure.—J. Lowe.

WINDOWS IN FRAME-HIVES.

IN reply to the inquiry made by "A. B. C." in page 119, I may state that I find windows nearly useless in frame-hives. In the first place they are so blocked by the frames that little can be seen of the interior of the hive through them; and in the next place the habit of examining every comb separately renders them altogether superfluous.

These are my views respecting windows in frame-hives; but if "A. B. C." should be of a different opinion, Messrs. Neighbour will readily supply the omission at a trifling addition to the first cost of each Woodbury-hive.—A DEVONSHIRE BEE-KEEPER.

BEEES AND CHLOROFORM.

THIS spring found me with three wooden and one common cottage-hive, all particularly strong. I had a swarm from each of the mansions; a swarm and cast from the cottage. August 5th I went round to collect rent: No. 1 mansion gave me a large and small box, containing 16 lbs.—good; No. 2, three small boxes, 16 lbs.—good again; No. 3, "it not being convenient," promised three small boxes in about a fortnight, weather permitting—good if true. The cottage tenants candidly told me, as they had but one room I must distrust if determined to have rent. Being old friends I let them alone, determined to have my revenge out of the five new cottages. No. 1, a large Yorkshire straw with a deep "eke," tenanted on the 2nd of June must go. My groom said something about digging a hole and fetching brimstone matches; on which I gave him a short extemporary lecture "on the folly of destroying these valuable insects," and told him he should see the wonderful effect of chloroform; but just then I remembered I had none. I gave three teaspoonfuls on doubled rag. All right, they are merry over the first taste; and I believe I felt some pleasure in thinking how soon they would "stop that game," and amused myself in watching about half an inch thick of bees remaining on the floor-board, coolly walk into their neighbours' house. Ten minutes—that is the time—up with the hive. Stop! stop! they are kicking-up a row. That is a bore. More rag and a double dose of chloroform. Still they talk. Gave them an ounce (cost 1s. 6d.). They are done at last. The hive is shaken, and I, for the first time, see what I take to be "all the bees in a hive,"—double the quantity I thought of. The queen must be found, because I wanted to see one, and also because "Bee-keeping for the Many" says she must be killed before her subjects are transported

to another colony; but the bees becoming particularly lively, and the evening rather dark, it must be given up, and they are placed on their own floor-board with their new friends over them.

Now for the honey. I thought there would be three stories and hoped for four. There are a few bees walking about, but it is all right. "The book" tells me a few will remain, which may be brushed out with a feather; but the more they are brushed the more bees come. The "eke" must be taken off—a proceeding the bees did not agree to, for they were creeping all over the place. At 10 o'clock p.m., I gave it up for the night, and placed my friends in a cool greenhouse until morning. At 10 o'clock next morning I found the house full of robber bees from all the hives. As a last hope I placed the hive in a wheelbarrow, and had it wheeled about for an hour to deceive the robbers, which proved effectual, as I now have the honey in a sieve, and there it must remain two days, says my book; but what in the world will "Jonas Jackson" say about my future luck after this?

I have now four hives of this year; two I want to take, and two I want to keep, all very strong indeed. Would you recommend another trial of chloroform, of course using a fresh sample? Would Mr. Woodbury kindly give me the distance between the glass of his uncomb-hives?

The frost of the 19th July cut several hundred acres of potatoes down to the ground. They are now making new tops.—AN ISLE OF AXHOLME BEE-KEEPER.

LIGURIAN BEES IN SCOTLAND—FERTILE WORKERS.

I HAVE been favoured by Mr. Alex. Shearer with a copy of *The Huddingtonshire Courier*, containing the following interesting article from his pen, proving that the Ligurians are asserting their wonted superiority. There can be little doubt that it was the existence of fertile workers which frustrated the attempts to rear a queen in the first of his artificial swarms, especially as I have this season found workers laying eggs in two instances in which royal cells had turned out abortive.—A DEVONSHIRE BEE-KEEPER.

"CULTURE OF LIGURIAN BEES.—It is nearly twelve months since I communicated to the *Courier* my experience in the artificial swarming of the Ligurian bees. Perhaps it may be interesting to your apianian readers to give the results of that trial, and my further experience. It will be remembered by those who take an interest in bee-management that I made two artificial swarms. The first one turned out to be a failure, not owing to any defect in the system, but because of the wet weather during the time the queen required to make her 'matrimonial' flights. It ended in there being nothing left but drone-brood; and notwithstanding I supplied her several times with bar-frames of brood-comb, that they might rear another queen which was really fit for her duties, she still reigned supreme, preventing any other queen coming forward to take her place; or rather, if the doctrine of parthenogenesis be a fact—and there is in this case strong evidence that it is so—that there are bees having all the appearance of workers, which have yet the power of laying drone eggs only. In all our searches for a queen in this hive we never could find one (and it was frequently done with the utmost care), which in other circumstances we never failed in finding. But it appears those bees which have the power of laying drone eggs will never allow any other queen to be reared. Such is the theory of those who hold by this doctrine. For my own part, I forbear giving any conclusive opinion on the matter—I would require more experience on the subject. I merely state the fact as we found it in our case. No bees being bred, they gradually died-off, and her neighbours began and robbed her in February this year. The second one was more successful; she has survived the winter, and given off a top swarm, and appears to be a hybrid between the Ligurian and common bee.

"The old, or original Ligurian, began egg-laying in January. On the 15th of June I made the first artificial swarm. I made another on the 22nd, and one on the 30th of June, and on the 10th of July she gave off a natural swarm, larger than any two of the common ones, and on the 16th a second—the latter was a small one, and the

person who had them in charge put it back the same evening. I went the following day and found the queen had not been killed, and, on examining the hive, found a beautiful queen, and also eight queen-cells, all in different stages of progress. I divided them, leaving the queen already hatched in one, and put the other into another hive, along with half of the bees, that they might hatch another queen for themselves, which they have done, at the same time cutting off a piece of comb having a queen cell sealed up, and gave it to a neighbour, who carried it nearly two miles in a box. When he turned up one of his hives, which had given off a top swarm a few days before, he found the queen-cell still unhatched. This he cut out, and inserted the Ligurian one in its place, which was hatched by the 22nd, as on the 23rd and 24th the bees in the hive manifested all those symptoms, so well known to bee-keepers, of her majesty being on one of her excursions to find the future king. The top swarm (having of course the old queen) being in such a prosperous state—laying numbers of young brood, I made another artificial one on the 22nd; thus making four artificial swarms and two natural ones from one hive, besides taking upwards of 25 lbs. of honeycomb from the artificial swarms, to give them more room for breeding, that there might be abundance of young bees out to begin on the heather when it is ready. I gave also a bar-frame of drone-brood to a friend, a bee-keeper in Edinburgh, whose Ligurian queen had failed in laying drone eggs (another very puzzling circumstance in bee-keeping). Had I been disposed, and had hives to put them in, I could have easily, from the same hive, made almost any number of swarms; but I am satisfied with the six in the meantime. If all the Ligurian queens are like the one I have, then the common bee cannot be compared with them as breeders. An acquaintance in Edinburgh, who got one last year, informs me that his has thrown off four swarms since May, and all strong. Mine would have been much stronger had not a great number of bees died in the spring by dysentery, caused, I imagine, by the stock swarm being kept in a wooden box. The moisture arising from the bees not being absorbed by the wood, it collected on the floor-board in such quantities that in their efforts to get rid of it they took the disease. During the winter and spring I shifted the comb four times into a dry wooden box, and each time they improved partially. At last I had a hive made on the same principle, in straw, by John Heriot, Longyester, which has completely cured them. I will never keep stock swarms again, during winter, in wood; it may do in summer, but certainly not in winter.

Another proof of the superior breeding powers of the Ligurian bee: out of eight good hives of the common bee, only two gave off a second swarm with me, all getting the same treatment. In order to keep the Ligurians pure, I have all the six young swarms at Longyester, where there are no common bees within nearly two miles of them. I will thus have a further opportunity of testing their merits with the common bee, and also the hybrid."

HOW TO DESTROY WASPS' NESTS.

I HAVE for years been more or less annoyed with wasps about this season of the year—those, I mean, that make their nests in some hole in the ground—and I have at times adopted various means to destroy their nests. I need not here enter into any detail how I have in former years proceeded to take them; but latterly I have adopted the following mode:—

I procure some coal-tar, a handful of fine shavings, or what is, perhaps, quite as good—a bit of an old mat, soak it well in the coal-tar, take a long stick—a broom-handle will do very well—and then in the evening about ten or eleven o'clock, when the wasps are nearly all gone home, I proceed to the nest and push the piece of old mat, now full of coal-tar, as far into the hole towards their nest as I can, and thus make them prisoners to die in their own castle.—G. Dawson.

[We have found that an effectual mode is to put a little spirit of turpentine into a wine-bottle; to thrust its neck into the entrance of the nest; place a little straw over the bottle, and burn it, so as rapidly to fill the nest with turpentine vapour. This is more prompt and less cruel, we think, than our correspondent's plan.—Eps.]

WEEKLY CALENDAR.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 72.1°, and its night temperature 49.0°. The greatest heat was 89°, on the 25th, 1859; and the lowest cold, 32°, on the 29th, 1850. The greatest fall of rain was 1.32 inch.

JOTTINGS ABOUT SOME BEDDING PLANTS OF 1863.

OBELIA Paxtoni sent out by Messrs.

Carter is one of the most effective of the bedding novelties of the current season. Its habit is so prostrate, the contrast of its light blue and white so perfect, its growth so free, and bloom so profuse, that it is a great acquisition. I was particularly struck with its excellence when contrasting it with a seedling raised here by a well-known nurseryman, Drummond, to whom I gave some of the plants I had from London. He thought his own good, but he will destroy them that his stock may not be mixed.

The *Tagetes pumila* is a very striking, spreading plant, not exceeding 12 ins. in height, and presents a mass of rich yellow blossoms spangling its good foliage.

The spring being so dry, and the summer warm, the slugs have not attacked it, for they usually mercilessly destroy its ally, the French Marigold. It is much benefited by an occasional watering with liquid manure.

The experience of all parties agrees as to the *Amaranthus melancholicus ruber*. In favourable seasons, and under proper management, it is a most valuable addition to the coloured-foliaged plants. Nothing equals it in brilliancy of colour when in a good light. Plants if small when put in do not thrive, the cold wind so dries the leaves: they should be 6 inches high in pots before transplanting into the borders. The winds and cold of May and early June almost destroyed the first lot. The growth of plants under circumstances apparently the same is rather irregular. Some of mine are a foot high, and nearly that across, while others close to them are at least one-third less. Those planted the first have never done well. This plant also enjoys weak liquid manure. During July the improvement in the growth and beauty was more marked. The *Perilla*, though so much more hardy, is very dingy and coarse as compared with the *Amaranth*.

There is a half-shrubby plant of loose growth with small silvery leaves (the name I forget), that I saw last week at Messrs. Garraway's nursery, at Bristol, used as an effective background of a ribbon-border. It was mingled with *Perilla*, which formed an excellent contrast in colour and growth. This firm had planted rows of *Amaranth*, none of which were prospering, the wind having spoiled the leaves.

I do not know what may be the future height or

size of *Calandrinia umbellata*. When 2 inches high it throws up its flower-stalk not exceeding 3 inches, carrying an umbel of rich red-purple flowers, which appear to be permanent and suitable for small nosegays. The foliage is so light and marked, that I expect it will form a nice edging of low growth. Is it a perennial and hardy?

For singularity of growth, and strictly a creeping plant, nothing can exceed *Aretotis repens*, with its long silvery branches that literally stick to the ground. If it has a blossom that contrasts with its colour it is very suitable for filling corners of beds. I should presume by its growth that it will be found an excellent plant to hang down over rockwork, when it would form a close substratum for flowers of a brilliant hue. It would contrast well with the dark blue *Lobelia*.

There is another plant that in the early part of the day presents a blaze of light red blossoms—*Mesembryanthemum tricolor*. Why called tricolor I do not know. Many white-blooming plants came up with the red, nor can I distinguish the one from the other by any difference of foliage. The period of blooming is but short, as it seeds so freely, and the plant lies so close to the ground that these seeds cannot be cut off without more labour than it is worth. Its roots are so very fine that I presume its natural and most suitable site is on stones, to which its silky roots adhere, that they may be nourished by the moisture always on rocks.

For distant effect an old-fashioned plant, *Oenothera acaulis*, with its showy white blossoms a few inches from the ground, is worthy of notice.

I cannot conclude my comments on these plants, selected solely from the catalogues of Messrs. Carter and of Messrs. Henderson & Son, without any previous knowledge of them, and solely by their descriptions, without expressing my satisfaction at finding the descriptions of the catalogues quite correct. To amateurs with small means and small gardens, who must judge and rear plants for themselves, it strengthens their confidence in their fellow men, and enables them for the future to trust firms to whom they personally are unknown. I am sorry to say this is far from being the case in purchasing fruit trees of some of the provincial gardeners, several of whom are as likely to send you the wrong as the right sort. So much is this the case, that I have long ago made it the rule with some firms never to buy a tree till I have seen the fruit on it. This is not, however, I believe the rule of the trade, who are so dependant on the care and honesty of their foremen.—B. J. S.

BOILERS.

THE boiler question has been ably discussed of late. The admirable papers of "G. A." have thrown considerable light on the matter, and will, doubtless, prove useful to many. He has, with rather more courage than is usually displayed on such occasions, put forth his own views of what a boiler ought to be, and given a plan which anybody may work out for his own profit. Judging from what I know of the action of heat on boilers, the

plan given at page 85 would be well worth trying, and I should like to hear of its having been carried into effect in all its details. Meanwhile, I wish to offer a few further remarks on the subject, for although I believe it is one that more directly concerns employers, still it is also important that gardeners should make themselves thoroughly acquainted with it, and this most of them have opportunities of doing, both from their own practice and from the reports of the experience of others.

In the first place, I would criticise what "G. A." says in regard to the nature of heat, not in a spirit of opposition, but with the object of inquiring further into the matter. From what "G. A." observes, the natural tendency of heat is to direct its course upwards. Now, in my view, it is to diffuse itself equally on all sides from the point of combustion into the surrounding air. The air thus heated becomes lighter, and is quickly borne up by colder, and, consequently, heavier air; so that, heat being diffused, heated air has no motion in itself until displaced by that which is heavier—in other words, that which has a greater specific gravity. It may not be possible to distinguish between heat itself and heated air, and perhaps it is of little consequence whether we can or not; but it is worth while ascertaining the truth while we are about it, and I will endeavour to make my meaning more clear by illustration.

If you light a candle and place it in the middle of a dark room, the light is diffused equally on all sides—that is, as nearly equally as we can judge; and it is my belief that the heat would be equally diffused, but, that being less subtle than the light, it, in combination with the air into which it is diffused, is more readily acted on by the cooler air, and is quickly borne upwards. The fact that there is more heat at 2 inches above the light than at half an inch from the side of it does not alter the case, since the heat that would otherwise be equally diffused all round is concentrated at the top by the upward current of air.

According to "G. A.," in speaking of the action of fire on boilers, the greatest heat is directed to that part which is directly over the fire. Now, I am not sure that this is correct. For instance: the blacksmith does not place the iron to be heated over the fire, where, according to "G. A.'s" theory, the greatest heat would be, but he thrusts it right into the fire—to the very spot where the blast of cold air, driven in by a powerful pair of bellows, comes in contact with the fuel; or if you take a common pair of bellows and blow up your parlour fire, you will perceive that where the nozzle of the bellows is directed there will be the hottest part of the fire, and, further, if you look into a furnace fire you will see that the greatest heat is about the bars, and although there may be more heat at 1 foot above the fire than at 3 inches below it, there will be more heat 1 inch below the fire than at 1 inch above it, for the greatest heat is where the air comes in contact with the burning fuel. Presuming this view to be correct, it shows the advantage of having hollow bars to the furnace, and that a great deal of heat is thus encouraged, but that is not enough.

I have said the greatest heat is at the point of contact between the fire and the draught of air, but the question is how to adapt this to the economisation of heat. Here I must confess myself at fault, for although, as I believe, the greatest heat is at the bottom of the fire, still the bottoms of the bars where the air comes in contact with them on its way to the fire are comparatively cool, and the same effect would be produced if a current of air could be made to play on other points than the bottom of the furnace. Leaving this ground, then, as untenable, we come back to the question of how to utilise the heat in its upward course—upward, not because of its tendency to fly off, but because it is pushed up by that which is to replace it. The most reasonable method of utilising this heat appears to be to intercept it, by breaking its direct progress, and throwing it into numerous directions instead of allowing it to pass off in a body, and this must be done in such a manner that sufficient draught is allowed for the fire to burn clear. This must not be overlooked, for it not unfrequently happens that in directing our attention to one point we are apt to overlook others. It is on this account, that although improvements are made from time to time, a perfect boiler has not yet appeared, and it is possible never will; yet "G. A." has suggested some changes, and I freely coincide with him that what he suggests would be a decided improvement.

He provides horizontal coils of pipes for the heat to strike against in its upward course, and having passed there it is again to break against the water-jacket, which is grooved to receive it. Still, in my opinion, a great body of heat is allowed to pass off unintercepted—for this reason: that although I believe the natural tendency of heat is to diffuse itself, still the pressure of the atmosphere tends to concentrate it into a column in its upward progress, narrower as it mounts higher, as is seen in the form the flame of a candle assumes. This, then, would allow the strongest heat even in such a boiler to pass into the flue.

It appears, then, that what is wanted is the means of intercepting, breaking, turning, and appropriating this column of heat, so that it shall not pass away from the boiler until no more heat is allowed to escape than will carry the smoke up the flue. This, of course, must be allowed for, or the whole contrivance will fail; and this probably will be a point of some nicety, for the boiler itself may be as nearly perfect as it could possibly be, and yet the least fault in the setting might spoil it. It would, however, be possible to avoid this; and I will follow the example of "G. A.," and give a few suggestions of my own, which, as a matter of course, are open to criticism, and so far from fearing to have defects pointed out, I shall be glad to be set right if I am proved to be wrong.

I do not know whether it is generally known, that when a piece of wire gauze or fine wire netting is held in the flame of a candle that the flame becomes dispersed, takes a wider scope, but unites after passing through it. This wire naturally intercepts a great deal of heat. Two or three such layers would absorb nearly all the heat, and allow the air to pass off comparatively cooled. Now, although I do not remember seeing anything of the sort, I do not think it would be impossible to cast hollow plates perforated with holes of about three-quarters of an inch in diameter, so that the plates would hold water and yet allow flame to pass through the perforations. By way of illustration I will suppose a metal dish such as is used to serve up large joints of meat, and which are made to hold hot water. Suppose this dish could be pierced with holes half an inch in diameter and about an inch apart, the holes to go through from top to bottom so that you could see through them, and yet the dish to hold hot water the same as before; and further, suppose three or four of such perforated water-plates to be cast of different sizes, of from 18 inches or 2 feet for the largest, and 1 foot or it may be less for the smallest; then we should have a water-jacket or a boiler made somewhat similar in form to Weeks's boiler—that is, tapering towards the top, only pipes either upright or horizontal are unnecessary excepting for the furnace-bars, which I would assuredly have hollow. The main part of the boiler would be a plain hollow water-jacket, and the perforated hollow plates would be fitted within this; the largest say a foot above the fire, the next about 9 inches above that, the next at an inch or so less distance above that, and, if another, a still less distance to be allowed between them—the hollow plates and water-jacket to be all connected, so that the water could pass freely through them all; the flow, of course, to be from the top of the water-jacket, and the return at the bottom of it in connection with the hollow furnace-bars.

There should be openings through the water-jacket to allow of a wire brush being introduced for clearing the boiler of accumulated soot, for this would be a matter of necessity in such a boiler; but with a ready means of introducing a brush the cleaning would involve a very trifling amount of trouble on the part of the stoker. With regard to the circulation of water, the boiler should be made so that the water could pass freely from the bottom to the top. This is all that is necessary as regards the boiler in the circulation of the water, for that chiefly depends on the fall of water in the return-pipe. If we examine into the principles on which hot water circulates we shall find that it does not depend on the nature of hot water to ascend, but on the power of colder water to push it up or displace it, and that the greater the weight of water in the return-pipe the more rapidly is the hot water made to ascend. If the return-pipes were twice as thick and held twice as much water as the flow-pipes, the mere construction of the boiler could offer no obstruction to the circulation of the water.

With regard to the draught of the flue, as "G. A." justly remarks, a boiler fire ought to be perfectly under control, and a good draught ought to be secured by sufficient height and breadth of chimney. But then there should also be the power to regulate that draught, for a great deal depends on that power, chiefly as regards economising fuel, but also for the safety of the plants.

A boiler constructed on the principles I have suggested may at first sight appear complicated, but I do not think it can be more so than pipe-boilers generally, or that it can not be made as strong and durable; nor is there any reason why it could not be adapted to heat buildings of various sizes, and be made larger or smaller as required. Certainly I think it will present a surface of water to the action of the fire both direct and indirect, that will make it capable of doing a vast amount of work at a comparatively small consumption of fuel.

I would rather give my experience of what has been done than merely endeavour to explain what might be done; and so I will take this opportunity of stating what I know of a boiler, concerning which, as far as I have seen, others have had but little to say—that invented by Mr. Messenger of Loughborough. One that I have the management of is, I believe, about 4 feet long, 3 feet high, and 2 feet wide outside, the whole being enclosed in brickwork. This is the nearest guess I can make, for I have no means of taking an accurate measurement. The boiler is composed of pipes which are three-sided and laid horizontally, three on each side of the fire, and a layer of seven over it, and another layer of six or seven over that. This arrangement presents the whole, or nearly the whole, surface of water in the boiler to the direct action of the fire; and this surface of water is necessarily very large in proportion to the size of the boiler, the furnace-bars also being hollow and forming part of the boiler. The fire plays about and between these pipes, and is very much dispersed: consequently a large proportion of the heat is intercepted. The only fault I find with the arrangement is the constant attention required in keeping clean, for the space allowed between the pipes is very narrow, and a small accumulation of soot will stop the draught; but this cleaning is but the work of five minutes each day when the boiler is in full work. It will be seen that, supposing each triangular pipe is 4 feet long and 4 inches wide at the base, it follows that each pipe presents 4 feet of surface to the fire; and there being twenty of these, there will be 80 feet of surface exclusive of the furnace-bars. The fire is also perfectly under control; for with good fuel, a clear flue, and a rapid fall of water, it is possible to get up the heat in an incredibly short space of time; and by shutting up the ashpit-door and closing the damper a shovelful of fuel will keep alight the whole day.

As near as I can understand there are two thousand feet of pipe attached to this boiler, nearly all of which is four-inch. Although the whole of it is not required to be heated except in case of frost, still the boiler will heat the whole and that effectively, and, as near as I can judge, at no greater consumption of fuel than I have used to heat 120 feet of pipe by means of a saddle boiler. By turning a valve the flow of hot water is stopped, but the return is still available, and the pressure of cold water is in no way diminished. This is no small matter for various reasons, but chiefly on account of economy in fuel and water.

In conclusion, I would say a word with regard to fuel. While living in the neighbourhood of London, I seldom ever burned coals either in a boiler furnace, or in a common flue: I have mostly been in the habit of burning coke, and very often have burned nothing but cinders. The Newcastle coals which are burned in domestic grates turn to cinders, and these when sifted make an excellent fuel for the furnace. Those who burn coal in the furnace use what they call inland coals, and these burn to a white ash, which is unlike the ash of the sea coal. In Staffordshire people burn coal in the parlour grate, and slack in the furnace. This answers very well, but the soot and smoke it makes will soon clog up a flue, and render constant sweeping necessary. —F. CHITTY.

COUNTY OF KILDARE HORTICULTURAL EXHIBITION.—Our readers will perceive by an advertisement in another column

that a Horticultural Exhibition in connection with the Kildare Agricultural Society is to be held at Naas on September 1st. Numerous prizes are offered for flowers, fruits, vegetables, &c., amounting to more than £100.

HEATING A SMALL PROPAGATING-HOUSE.

I AM about to put up a small span-roofed propagating-house for early use, say in the middle of January. Will you give me a little advice on the subject? The house will be 20 feet long and $7\frac{1}{2}$ wide, inside measure. There will be a path through the middle, and on one side will be a bed of $2\frac{1}{2}$ feet in width for plunging pots of cuttings in, and on the other a stage for the cuttings when potted. Under the bed I purpose having a trough made, I suppose of cement, and having the pipes laid in it, so as to be covered with water. How am I to make the tank watertight? I am told that a pipe passing through brickwork forming a tank will, when heated, expand and cause a leakage. How is this to be prevented? What width and depth should the trough be, and what size the pipes—a flow and return of course? and then what size should the pipes be for top heat?

Added to this house will be a pit 40 feet long and about 4 wide, to which I purpose having a continuation of piping from the house. Should the piping be of the same size as that in the house, the object being merely to exclude frost from the beginning of March?

Perhaps you will be good enough to say what kind of boiler will be best adapted to my purpose. Some recommend a saddle, some a tubular one, some one thing, and some another. Have you any knowledge of Riddell's Patent Slow Combustion Boiler? It seems to be simple in its construction, and it is said by the patentee to have several very desirable qualities, such as requiring little fuel and attention, no expense in setting, and that it can be so easily regulated as fairly to entitle it to the name given it. The patentee of this boiler has, to me, a novel plan of connecting hot-water pipes. At the ends of the pipes are flanges—made square. These are drawn together and secured with four screws and nuts. At the junction of the pipes there is a ring or collar of something like gutta-percha or some such material of an apparently elastic property, which renders the pipes perfectly watertight, so it is said. Perhaps you have seen the plan and can speak of its merits or defects. A more simple mode than this of putting together and removing pipes cannot well be devised. If the plan is effectual it deserves to be made known; and it would be well to make it known if it is not effectual, so that the public may not be deceived and disappointed.—C. S. E.

[First, as respects the tank, the fear of expansion is next to groundless. There is more danger of leakage from building on an insecure foundation. The tank should consist of brick well wetted, laid in cement, and a layer of cement all over. The tank for the place should be 2 feet wide and 5 inches deep. Were we disposed to be economical, we would dispense with pipes through it, and make the tank into a flow and return by a division down the middle and an opening at the end. We presume you mean covering with slate. We find no fault with the pipes through the tank except for economy. It is certain that with the pipes there you are sure of bottom heat, even if you have a leakage, and that is not likely if your foundation is good, and the cement good and used the instant it is made.

For such a place we have recommended a small wooden tank, or box, elevated on piers or battens, so as to give room beneath for many things. The simplest plan we have met with was a wooden trough $2\frac{1}{2}$ feet wide and $6\frac{1}{2}$ inches deep, divided down the middle. It had a space for water $3\frac{1}{2}$ inches deep, and was covered above with thin house slate, and thus about 3 inches were left for setting or plunging small propagating-pots.

For such a tank as yours two three-inch pipes will be ample. If the brick sides of the tank are exposed, three three-inch pipes will do for top heat; but if not exposed much, you ought to have three four-inch pipes for early work. It is had economy to have pipes excessively hot. If the water in them is rarely above 160° to 180° all the better. Of course, if all your pipes are close, with air-pipes at the highest point, the mere level, if all above the boiler, is of

less consequence. These levels, however, must be kept in view, if you mean to heat the 40-foot pit from this house. Your simplest plan would be to place the border, if practicable, between the two places, and take heat as required for either place by valves, or take the flow-pipe into a cistern higher than any of the pipes to be heated, and from thence take a flow for top, another for tank in the propagating-house, and one for the pit, to be regulated by plugs as desirable. If your pit were 6 feet wide, two three-inch pipes would do all you require, and you cannot well have less for a four-foot pit—that is, 80 or 90 feet in all.

Any of the simplest boilers will do all you want. We believe Kiddell's to be very good, but we take all high recommendations with a little reserve. We have worked in our time most of the kinds of boilers advertised in these columns, and we find them all good if well set and well managed. If we have a prejudice, it is for tubular or conical boilers; but we do not forget, that in the largest establishments and under the greatest gardeners, there is a general tendency to a return to some modification of the old saddle-back. We decline, therefore, authoritatively to say what boiler is best, and much prefer that our readers would exercise their own judgment.

We have not seen the flange spoken of in use, but we have no doubt it will answer. We have repeatedly detailed how Mr. Lane and other proprietors of large establishments use Portland cement for forming the joints, which so far as first cost and ultimate economy is concerned we consider far preferable to iron filings and sal-ammoniac. Where large fires are used we would prefer the joints close to the boiler to be iron.—R. F.]

HINTS TO AMATEURS ON THE USE OF SOOT AS A LIQUID MANURE.

WHILE the materials for liquid manures are often difficult to procure by the amateur gardener, and frequently tedious in their preparation, injurious in their application, or offensive in their smell, soot sufficient for the purpose is almost everywhere at hand, and in a few hours can be prepared for use; and if amateur gardeners were more generally aware that no manures can be taken up in a state of solidity by plants as food, and that they can only absorb them in a gaseous or liquid state, and to which state all solid manures applied to plants must be previously reduced before any benefit can be derived from them by the plant, they would in many cases facilitate the process by using them in a liquid state. Sir Humphry Davy characterises soot as a powerful manure, possessing ammoniacal salt, empyreumatic oil, and charcoal, which is capable of being rendered soluble by the action of oxygen: consequently, when soot is dissolved in water there is no waste, while if sown by hand in a dry state, a great portion of its ammonia, which is one of its active ingredients, is volatilised, and is dissipated in the atmosphere. Soot when used as liquid manure gives vigour to the plant without grossness, and imparts a healthy green to the foliage without the least chance of injury to the plant. In fact, watering a sickly plant with a weak solution of soot-water is the surest and safest means of restoring it to health.

In preparing soot-water it is only necessary to throw a few handfuls of fresh soot into a pail of water, and after stirring it up to leave the mixture for a few hours to settle, and when the liquid has become clear, it is fit for use, and can be given once a-week in summer without the least risk of injury to the plants, whether in pots or in the open ground.—GEORGE GORDON, A.L.S.

GLADIOLUS DISEASE.—I see in your Journal of the 11th inst. you mention the disease in collections of Gladioli near London. I find the same in many of mine here (Aberdeen), and have been puzzled what to apply as a cure. The flower does not seem in the least affected by it; but the leaves of several are entirely gone, while others are perfectly fresh and green.—A READER.

THE disease which so much resembles the Potato disease is universal among the Gladiolus tribe. It was correctly

described by one of your recent correspondents. It is very curious that some roots of a patch planted at the proper time have never vegetated. They remain in the ground apparently fresh and firm, but without any further signs of life. When Tulips or Hyacinths thus fail to grow they speedily die and become rotten. Has the firmer tissue of the Gladiolus bulb greater power to resist decay? or will these dormant roots awake into life next spring? Should they be taken up or left in the ground to take their chance?—B. J. S.

CLERKENWELL FLOWER SHOW.

THIS annual Show of plants and flowers belonging to the working classes and children of Clerkenwell was held on the 19th and 20th inst. in the schoolroom of the Lamb and Flag Ragged School, Clerkenwell Green, and was in every respect a most interesting and successful Exhibition. It differs somewhat from the other exhibitions of the sort which have been held in London, inasmuch as its principal aim seems to be to encourage the cultivation of plants by children. Most liberal prizes are, however, offered for competition among adults, and particularly among working men; but the fact of the prizes in the latter class being offered for collections of six plants necessitates the number of exhibitors being very small indeed. We must, however, remark that the six Fuchsias which won the first prize in this class were exceedingly fine plants, and had evidently been grown by a man to whom the cultivation of plants was no novelty, and the same might be said of the winner of the second prize. The children's plants, however, formed the greater part of the Show, and were to us much the most interesting part of it. We very much doubt if it could be possible for better plants to be exhibited by children living in such a neighbourhood. What struck us most was the remarkable cleanliness of every single specimen exhibited. We did not see one dusty or dirty leaf in the whole collection, which clearly shows that some one has impressed upon the youthful exhibitors the great necessity of washing their plants in order to keep them in good health.

Among the other plants exhibited were Apple, Plum, and Orange trees, Ferns, and one or two very nice plants of *Colus Verschaffelti*. Prizes were also offered for cut flowers grown by the exhibitors; but, as might be expected, there was no very keen competition in this class. The first prize was won by a very tastily-arranged pan full of *Fuchsia* and *Ageratum* blossoms edged with variegated Mint. Several kind patrons had sent bouquets of flowers, which were on sale for the benefit of the schools, and Mr. Cutbush, of Highgate, had sent some which were most beautiful and most tempting. In the evening of the second day Mr. Bodkin, who is another inhabitant of Highgate, attended and gave away the prizes. When we mention that these latter were awarded by Mr. Broome, Mr. Dale, and Mr. Gordon, every one will be satisfied that there was no cause for grumbling.

And now we will take the opportunity of making one or two suggestions, which we are sure will be taken in good part by the promoters of the Clerkenwell Flower Show, who evidently take such very great pains to secure success.

In the first place we would suggest that the plants which win prizes should be more prominently noticed. We found it quite impossible in most instances to ascertain which were the prize plants, as the card which ought to have been placed conspicuously in front of the pot was often lying in the pot on its face. We think these prize-cards should be rather ornamental than otherwise, as they are much treasured by the successful exhibitors.

Looking at the number of plants exhibited, we think it would be beneficial to form the different sorts of plants into different classes, and not to let plants which are so very dissimilar as the *Lobelia* and *Fuchsia* compete with one another.

We cannot help thinking that the good effects of the Flower Show would be much more widely extended if more prizes were offered for single specimens, and fewer for collections. We find from experience that the poor do not keep "collections" of plants, and we must begin by adapting our classes to the exhibitors.

In other respects we think it would have been impossible

for the Clerkenwell Flower Show to have been more successful; and we do not hesitate to say that the plants exhibited by the children would have carried off the palm at most, if not all, of the exhibitions of the sort which have been held this year in the metropolis.

In one most important respect the promoters of this Show set an excellent example to others, for they not only get up a Show and offer prizes, but evidently take great pains to instruct the exhibitors how to grow their plants successfully. The childrens' plants could not otherwise have been so creditably grown and exhibited.

THE EARLY-FLOWERING MOOR HEATH.

ERICA CARNEA, *Linnaeus*.

SYNONYMS.—*Erica herbacea*, *Wendland*. *E. saxatilis*, *Salisbury*. *Gypsocallis carnea*, *D. Don*.

Nat. ord., HEATHWORTS.

THE *Erica* is one of the unfortunate genera among many others that has come perfected, as it were, from the hand of the great father of our artificial system, to suffer amputation and distribution in after ages; for Professor Don, in his clever arrangement of the order *Ericaceae*, places our present plant in his new genus *Gypsocallis*—principally on account of its flowers being urceolate, or bellying out towards their base, like an old-fashioned pitcher, and their stamens being exerted, or projecting beyond the mouth of the corolla. And although every one may not agree in the separation, still all must be ready to pay that tribute of praise due to the very eminent ability of the late Professor for his acuteness of observation and depth of botanical research, but which nevertheless seem to have rendered him more nice in his generic divisions than plain botanists admit to be necessary, or indeed than is useful to the practical man; for certain it is that the extension of our botanic vocabulary, and perplexing increase of synonyms, form considerable drawbacks to any advantages that may accrue from nicer distinctions.

The name *Erica* is derived from the Greek *ereiko*, to break, from its supposed quality of breaking, or rather dissolving, the stone in the bladder, or, according to some writers, from the brittleness of the plants; that of *Gypsocallis* is from *gypos*, lime, and *kallistos*, most beautiful, the plants being very elegant and inhabitants of calcareous soils.

The Early Moor Heath is a neat little bushy undershrub, which grows about 6 inches high, clothed with evergreen, linear, glabrous leaves, arranged in whorls of four along the stems, and pendulous flowers, which are disposed in terminal racemes directed to one side; small, pale red, or flesh-coloured, conical in shape, and produced abundantly from January to April. The plant, like those of other hardy kinds, grows freely in any light sandy soil or peat earth, and makes a most desirable subject for the front part of the flower-border or for edging round an American-bed, as it bears cutting back without injury, and is perfectly hardy, braving our severest winters with impunity. It is a native of Austria, South Germany, and Switzerland, and is easily increased by cuttings; but as its procumbent branches increase freely in any light soil, a more convenient mode of propagation is by layers, which will root sufficiently to admit of separation in eighteen months.

The *Erica carnea* is an old inhabitant of our gardens, having been introduced in the year 1763.—GEORGE GORDON, A.L.S.

AMARANTHUS MELANCHOLICUS RUBER AND LONICERA AUREO-RETICULATA.

I HAVE not yet seen any remark on the injury which the leaves of the *Amaranthus melancholicus ruber* sustain from watering overhead. Drops of water falling on the leaves discolour them, and the spots seem to spread so as to injure the whole leaf.

With reference to planting-out *Lonicera aureo-reticulata*, I observe that the plant is no exception to the general rule that coloured leaves lose their brilliancy from want of heat. Two plants have thriven perfectly in the open air in a southern aspect this summer, but the leaves have lost the

bright gold-lacing or reticulation and have become dull and blurred-looking, offering a great contrast to a plant under glass.—A CONSTANT READER, *Dublin*.

NOTES ON GARDENS PUBLIC AND PRIVATE.

NO. 3.—VISCOUNT HOLMESDALE'S, M.P., LINTON PARK.

NO reader of THE JOURNAL OF HORTICULTURE needs to be told, that amongst the most practical and accomplished of our modern horticulturists none stand higher than the able and intelligent gardener to whom the management of Linton Park is entrusted; while of the place itself they have often heard so much that my few rough notes will lose much of their interest. As, however, they are intended not to be descriptions of the places visited, but just what I have called these short papers, "Notes on Gardens," I do not profess to tell what are all the trees grown, or the shrubs planted, or give minute plans and descriptions of the bedding-out. I shall, notwithstanding these disadvantages, give my recollection of one of the pleasantest mornings I have spent during the present summer.

Linton Park, known formerly as the seat of the Lady Julia Cornwallis, but since her marriage as that of Lord Holmesdale, lies pleasantly situated upon the slightly-elevated ridge of chalk hills which run along the north-eastern portion of the county, ending at Folkestone; and, being halfway down the hill, it is quite sheltered from the northerly and easterly winds, lying fully open to the south and west. While thus enjoying an immunity from those piercing blasts, which in the spring months sweep like a sirocco along the coast, it nevertheless has a good deal to bear from the south-westerly gales which are so prevalent in this part of England; and judicious care has evidently been exercised in former days to plant extensively for the protection of the house and grounds from those winds. The house itself is a plain building exteriorly, but is undergoing a thorough renovation inside. The walls and ceilings of the reception-rooms are all being painted by hand; and the suite will form one of the most beautiful and exquisite specimens of taste and art to be seen in England when they are completed. The pleasure grounds are situated in the rear of the mansion, from which a series of terraces lead down to the lower portion of the ground. The pinetum lies to the left, containing, as I shall have to notice, some very fine trees; while the conservatories, greenhouses, and kitchen garden are situated at the back of the house. A noble avenue of Elms leads out to the Maidstone road in the front of the house, and another to the church at the right hand. Some magnificent Elms are to be found, not only in these avenues, but in other parts of the grounds; and to me, coming from our treeless neighbourhood, there is always great pleasure in the sight of such luxuriant foliage as this park affords.

Knowing but little of Mr. Robson save as a collaborateur in the pages of THE JOURNAL OF HORTICULTURE, I yet felt assured from the hearty and genial character of his writing that I should meet with a cordial reception: nor was I disappointed. The greatest kindness and hospitality was shown to me; and after a very pleasant morning I was enabled to go on to other avocations not far off, which had especially called me from home.

The readers of your pages know very well, I think, that I have been a somewhat strenuous opponent of the bedding-out system as it is carried to extremes now-a-days. Well, after visiting Linton one has only to say before we condemn it altogether. See what it is when carried out under the most favourable auspices, as it is there under the able management of Mr. Robson. There were two things that struck me very forcibly as to the principles on which he managed to produce these admirable effects. One was that he employed, comparatively speaking, very few varieties, and that he was very particular that nothing should interfere with the oneness of colour in each particular flower. Thus, of course, all Verbenas with eyes would be excluded—in fact, Purple King, and another, a pink flower, were, I believe, the only kinds employed in the place; but even the dark horseshoe tint in many of our Geraniums was sufficient to exclude them from use. The plain green foliage or the simple variegated ones being those only employed, such

flowers as Herald of Spring, Mrs. Pollock, or Sunset would be thereby excluded.

The grand central bed, an oval measuring (including the grass border of 3 feet), 90 feet by 68, was one of the most brilliant sights that could possibly be imagined. A large star formed the centre of it. This was filled with yellow *Calceolaria*, the star itself being formed of *Perilla nankinensis*, and alongside of it the white *Alyssum*, forming thus a double line of dark purple and white, which was very effective. At the distance of a few feet there was a scroll pattern, formed in the same way of the *Perilla* and *Alyssum*; while what, I believe, ladies call a pinked or scalloped border formed in the same way ran round the outside of the bed, making a number of small triangles. All the space between the border and the centre star was filled-in with *Shottisham* Pet variegated *Geranium*, which Mr. Robson likes better than any for this purpose, inasmuch as the foliage is very much cupped, and thus exhibits a good deal of the white variegation. The outside triangles were filled with *Tom Thumb*, which Mr. Robson thinks still unsurpassed, unless it be by *Perfection* or *Attraction*; while a border of *Golden Chain* finishes the bed. It will thus be seen that this grand bed, so effective in its arrangements and so striking in its *tout ensemble*, is really formed with only six varieties of plants, and I question very much whether it would be possible with a much larger variety to make it as beautiful. The side beds were in scrolls, and several different varieties both of *Scarlet* and variegated *Geraniums* had been tried here; but with the exception of *Attraction*, I do not think that for these purposes *Tom Thumb* was beaten. *Bijou* Mr. Robson considers too lanky in its growth for his purpose, and *Flower of Spring* is not so white in the foliage as some others.

While thus only a few things are used here, others are tried in different parts of the ground; but it will be clear to any one, that in this central point of attraction experiments must not be tried, and only such things used as are certain in their results. Amongst those things which have been experimented upon this year have been *Coleus Verschaffelti* and *Amaranthus melancholicus ruber*, the former a complete failure, and the latter a great success; but I gathered from Mr. Robson's account of it, that it requires to be grown in the house until tolerably late in June before it is planted out, the earlier plants having been all injured, but the centre row of it in the roseray thus treated was one of the most effective lines that I have seen this season. The colour is more lively than *Perilla*, and yet affords as good a contrast to other bedding-out plants. It will, probably, too, like the *Perilla*, bear pinching-in, so as to make it more manageable as to height and breadth. *Centaurea candidissima* also promises to be very useful as a white-foliaged plant, and will, I doubt not, be found largely employed here in a little while. *Cineraria maritima* is also a great favourite, and deservedly so, its foliage being very beautiful and distinct.

In the pinetum there are several most interesting trees—fine specimens of *Araucaria imbricata*, *Pinus insignis*, *P. pinsapo*, *P. nobilis*, *Cedrus deodara*, *Thuja Lobbi*, and other well-known members of this tribe. With regard to the first of these I mentioned what I had noticed at Mr. Ivory's, of Dorking, that there were two varieties. This Mr. Robson confirmed, and said that when a plant throws out only four limbs it was sure to form an indifferent tree, but when five or six that the tree would be sturdy and well-formed. With regard to the *Deodar*, the opinion has been started by some whose names stand high in the botanical world that the three species *C. libani*, *C. africanus*, and *C. deodara* are only varieties of one species; and so far as the affinity of the *Cedar of Lebanon* and the *Deodar* is concerned it seems likely enough to be correct, judging from three trees of the latter here planted near to one another, in one of which the drooping character is almost entirely absent, and a limb taken off might very well pass for one of the *Cedar of Lebanon*. But the glory of the pinetum, though not itself a *Pine*, is a beautiful *Cork tree*, I believe as to size and beauty a unique specimen—in this part of England at any rate. It is fully 20 feet high, in most robust health, and forms a very pretty and striking object. There were also a fine *Catalpa* and a magnificent *Copper Beech*. Amongst other curiosities, too, was a fine plant of the old double white *Camellia* standing out in the open ground as a

standard. It is supposed to be about thirty years old, and blooms admirably in its present position. Time and space would fail me to recount all the interesting things I noticed here; but, as may be supposed, order and good management pervade the whole of the establishment.

Mr. Robson's own residence displays not only his own excellent taste but the liberality of his employers, being suitable in every way for the requirements of one upon whom so much responsibility rests. Many were the subjects on which we had much pleasant chat together—Nesfield's barbarisms, which, by-the-by, Mr. Robson to some extent patronises, as the large bed of which I have spoken is in winter levelled and laid out in scroll-pattern; *Spergula pilifera* and its total failure; and novelties of various kinds. We forgot, however, orchard-houses, in my opinion concerning which Mr. Robson, I know, quite coincides; our only regret being that the time was too short for all we needed. But we had each to leave early—I to my work, he to his drill; for our friend handles the rifle as well as the pruning-hook and the pen, and I am sure does it well too. It was inspection-day, and so Sergeant Robson was to be at his post. Our roads were in an opposite direction, but we parted with the hope that we should meet again in these beautiful grounds, and have another opportunity of talking over our favourite subjects.—D., *Deal*.

CUTTING-OFF MIMULUS SEEDS.

A PERSON of long experience in an extensive garden is much surprised at seeing an inquiry in last week's *Journal*, Whether cutting off *Mimulus* seeds will cause the plants to blow in autumn? It confirms a frequent observation that has occurred of how ignorant of or indifferent to the commonest results cultivators are, and it is much doubted whether removing the seed when fully formed will produce the object desired.

The removal of the seed-vessels before they fill sends back the nourishment to the plant, which they otherwise absorb. Let any one try two plants of *Sweet Peas*; by removing the seeds from one as soon as the flowers fall, he will find the plants not only continue blooming, but putting out fresh leaves, and they will do so as long as the temperature allows any flowers to remain out of doors. Let the other ripen its seeds, when they and the haulm will wither together very rapidly.

The removal of *Rhododendron* seed greatly assists the forming strong buds.—A. P.

SUCCESSFUL ORCHARD-HOUSE MANAGEMENT.

THE successful management of orchard-houses appears to be pretty general this season. Gardeners are fast learning this new branch of culture, as they are sure to do if required. The class which has overcome so many difficulties in cultivation was hardly likely to find the growing a *Peach* in a pot a serious affair.

I have never hesitated to recommend the orchard-house to any person keeping a regular gardener, but have had doubts where such has not been the case. Glass houses of any sort, unless filled with *Cacti* only, require daily attention, and where this cannot be insured persons had better think twice before building one, particularly if heated. Who has not seen a greenhouse built, not because the owner of the garden loved flowers, but because it was the thing to have a greenhouse?—a house containing plants which all thought it a trouble to attend to; sometimes watered, sometimes neglected; at times almost burnt, at others frozen. Though the orchard-house is no trouble for six months of the year, it requires daily attention during summer, and cannot be neglected with impunity. It is a singular fact, however, that amateurs in this neighbourhood have beaten regular gardeners, I believe because they have nothing to unlearn. Amongst the most successful I may mention M. Brown, Esq., of Lenton, near Nottingham; his trees have been managed entirely by himself and family. I was told he had a very fine crop, and heard some of his friends tell him they would come and see him when his *Peaches* were ripe.

He replied, "I shall be glad to see the whole of the Chess Club, and they shall eat what they like." The remark was made, "You need not expect many Peaches the next day, we shall eat them all." The answer to which was, "Will you?" Well, the visit was paid, and a most pleasant one it was; and though we all did our duty, I question if a casual observer would have missed the fruit eaten if he had gone into the house next morning. I know, of course, what my own success has been, and I have seen what my friend Mr. Rivers has done, but I can tell him we are both beaten by Mr. Brown. The Peaches were not only numerous but magnificent. The house is 55 feet by 15, a lean-to. It contains seventy trees, twelve of which are planted against the back wall; nine are standards planted out in a bed in the centre of the house; fifteen are dwarf trees planted in the front border, and thirty-four are in pots. There were on the wall 500 Peaches; on the standards upwards of 1100, and 130 Nectarines; on the small trees 900 more—in all 2700. What could a club do in such a house in one evening? Let us have the run for a week, and we might make an impression.—J. R. PEARSON, *Chilwell*.

GROWING PARSLEY UNDER DIFFICULTIES.

AMONGST all the varied demands of a large establishment on the resources of the garden, there is scarcely any more regularly made throughout the year than for Parsley. In the spring months, especially after there has been a continuance of keen frosty weather, scarcely a handful of nice Parsley can be found, except what may have been under cover. In the neighbourhood of London after a sharp winter, and especially when keen easterly winds have prevailed throughout April, a small handful of Parsley is not to be had for less than sixpence, and sometimes more will be paid for it.

Parsley, in the estimation of many persons, will grow at any time and in any place, and I have frequently heard surprise expressed by such when told that from a combination of causes it has been a very scarce article. It is also well known to all who have had to supply an establishment with garden productions how fidgety the cook will be even about a little Parsley.

I have had for a series of years splendid Parsley, so much so that part of it had sometimes to be cut down and wheeled away by barrowfuls; and again, for nearly three years in the same garden, I have been unable to grow a respectable row. Do what I could, it was always attacked at the roots by maggots, and what is very popularly known by the name of wireworm (snake millipedes). Just before sowing I have quite saturated the soil with very strong liquid manure from the stable yard, thinking that possibly they might thus be killed, and hoping that they might not come from the adjoining ground; but, in the course of a few months' time, they would be at their work of destruction again.

Another plan which I have tried was to slack a quantity of lime in water, and, pouring off the water into common watering-pots, to give the rows of Parsley a thorough soaking with the liquid. Even after this I have at times scarcely been able to produce it in anything like a creditable condition. These root-destroyers of Parsley eat into the roots and very often work their way into the bottom of the leaves. They cut into the roots where these are very small—it may be not much thicker than to hold the intruder—and whenever this is the case, the Parsley will soon assume a brown and foxy appearance, and you may give up all hope of its ever proving useful.

The soil of the garden where I was so annoyed with these underground destructives was a light, rich, free loam, which generally grew every kind of crop very well. Cauliflowers were liable to club. In another garden of very different soil, I endeavoured for some seasons to grow Parsley by sowing it in the usual way—that is, in the open ground; but owing to the nature of the soil I very seldom succeeded. It was a strong brick earth, almost inclining to clay, which, when dug up in winter, would remain just as it left the spade. If worked while in a wet state it would soon clog the instrument which was used; and, on the other hand, if allowed to remain untouched till quite dry, a fork or spade would make little or no impression upon it, from its having

become so very hard. When taken just between a wet and a dry condition, it would break away from the five-tined steel forks in beautiful order; and if the crops only started well they would generally be first-rate. I experienced very great difficulty in growing Parsley in this soil, by sowing it in the ground in the usual way. First, there was the uncertainty of being able to hit the proper time to sow it, when the soil was in a free and well-broken-down condition. Secondly, if fortunate enough to do that, there must be moisture enough in the soil to cause vegetation. Thirdly, fine weather must continue for some time after the seed has vegetated, otherwise it was quite certain that the slugs would carry off every plant, as they will quickly do while the Parsley is in the seed-leaf, and even much later.

However annoying slugs are to the grower of Parsley, I have found a means of preventing their attacks, and I can have good Parsley even in such soil as I have stated above.

I filled a quantity of small pots in which the bedding plants had been, using any rough materials, even what fell under the potting-bench. The Parsley was sown, and the pots placed upon coal ashes in a cold pit, which was then shut up. I kept them regularly watered; and as the young plants grew gave more air. The Parsley remained in these pots until the leaves were from 4 to 6 inches long; and it was then planted out in a piece of ground while in the course of digging, and the result proved worthy of all this care and trouble.—G. DAWSON.

HISTORY OF HEDGES.

THE earliest enclosures in England appear to have been in Kent and Essex, these being the first fields of Roman operations, and seem to have been formed of Hawthorn, Sloe, Crab, Hazel, Dogwood, &c., taken from the woods where they naturally grew. The earliest published account we have of enclosures is by Sir John Fortesque, who mentions the progress that had been made in planting hedges and hedgerow trees before the end of the fourteenth century; and towards the middle of the next we find the prelates and great barons enclosing land around their castles, which were called their demesne lands, which they kept in their own hands, and cultivated for their own use, much as our private parks are at the present time.

In 1523 Sir A. Fitzherbert wrote "The Book of Husbandrie," in which he points out the great advantage of enclosures, and recommends "quyck-settyng, dyehyng, and hedgyng," and gives special directions about the "settes," and the manner of training a hedge. Hawthorn hedges are distinctly stated to have existed in the gardens around Windsor Castle in the reign of Henry V., and are described by James I., of Scotland, in his poem, "The King's Quair," written by him while he was a prisoner there. Hedge planting, however, made slow progress in England until after the introduction of the Flemish system of husbandry into Norfolk about the end of the seventeenth century; and so rapidly did they increase, that by the end of the eighteenth century they had entirely changed the face of the whole country.

Although we now see many excellent examples of hedge management in many parts of the midland counties of England, still, as a whole, such fences are inferior to most of those in the best enclosed districts of Scotland, where, however, the use of fences of any kind is of far more recent date. Major, a native of Berwick, says in "Historica Britannica," published in Paris in 1526, that the Scottish peasants "neither enclosed nor planted, nor endeavoured to ameliorate the soil" in his day. Indeed, until the breaking up of the feudal system about the middle of the last century, and the swallowing up of numerous small pendicles into larger holdings, the use of fences to any great extent in Scotland was both useless and impracticable—at least, so long as the "run-rig" system, as a united system of protection, was in use.

The first introduction of the use of hedges into Scotland was, strange enough to say, by the soldiers of Cromwell, who also at the same time introduced the use of the close-headed Cabbages. The first of their hedging was exemplified at Inch Buckling Brae, near Tranent, where so recently as 1804 the remains were to be seen in a line of aged Haw-

thorn trees, long since removed; and the next was at Tintarig Castle, near the head of Loch Tay, the "Domus Ulturnus" of the Breadallane family.

The earliest account of the propagation of hedge plants and their management even in England does not date prior to between three or four hundred years, and the published directions then given refer to their uses as protection merely to plantations, gardens, and small paddocks near the house; and that Holly plants were mixed with Thorns, both being procured from the woods, where they grew spontaneously. The rearing of such plants from seed was not practised even around London till shortly before the time of Evelyn; and in Scotland not till after the establishment of the nurseries of the Dickinsons at Hassenden Burn, near Hawick; the rearing of such plants is said to have laid the foundation of the great commercial houses of the Dicksons in Scotland.—(*Scottish Farmer*.)

[The writer in our contemporary is wrong as to the time of hedges being introduced into England. "A grove for making hedges is mentioned in Domesday Book (Middlesex, fol. 127). Hedges and ditches also are mentioned as boundaries in many Anglo-Saxon grants of lands. Moreover they were protected by law. If a freeman broke through a hedge he was liable to a fine of 6s. A coroll was to keep his farm well enclosed both in winter and summer; and if damage occurred to any one from a neglect of this law, or even from leaving a gate open, the careless husbandman was liable to pay for the damage.—(*Wilkin's Leges Saxonice*, 4, 21.)]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE August meeting of the Entomological Society was held on the 3rd instant, T. P. Pascoe, Esq., F.L.S., one of the Vice-Presidents, being in the chair. Numerous additions to the Society's library were announced, consisting chiefly of foreign publications presented by the Natural History and Entomological Societies of Moscow, Stettin, and Berlin. Messrs. Hagen, Brauer, Zeller, &c. An account was given of the entomological captures made by Mr. F. G. Waterhouse during his recent journey of exploration across Australia. Upwards of 2000 specimens had been captured chiefly in the northern half of the continent, comprising a great number of species (although apparently poor in the number of individuals), which evidently bore a greater general affinity to the insects of the islands of the Eastern Archipelago than to those of South Australia and Van Diemen's Land. The Rev. Handet Clark exhibited the species of Water Beetles captured during this expedition, consisting of seventeen species, of which no less than thirteen appeared to be new to science.

The Secretary stated that on carefully examining the silken tissue found upon a mass of Chicory exhibited at the last meeting, some specimens, much rubbed, of *Ephestia elutella*, a minute Moth, had been found, the caterpillars of which were doubtless the fabricators of the tissue.

Mr. Stainton exhibited some Alder leaves containing larvae of the beautiful little Moth *Tinagma resplendella*, burrowing within the midrib or leafstalk. When young they impart a slight curve to the leaf, by which their presence may be detected. Subsequently they mine along one side of the midrib, returning by the other side, and finish by forming a blotch upon the leaf. Mr. Stainton added, that not only were the characters of the mines of leaf-mining Lepidoptera of high importance for the discrimination of species, but he considered that the mines exhibited characters of generic value, to which regard ought to be had in the future classification of the family.

Mr. Hayward exhibited the pupa and the perfect insect of *Oecypus ater* which he had succeeded in rearing from the pupa state, the larva having been found in a cavity in a piece of Elm wood. Entomologists had long been aware of the difficulty of rearing the insects of the family Staphylinidae, to which the *Oecypus* belongs.

Professor Westwood directed attention to the ravages committed on Willow trees in Essex by the Weevil *Cryptorhynchus Lapathi*, the larvae of which had attacked some of the rarer species of Willow (making cylindrical burrows of considerable diameter and length in the stems), to such an

extent that the growers were in fear of the destruction of their plantations.

Mr. Douglas Timmens gave an account of the successful rearing of *Papilio Machaon*, *Thais Cassandra*, *Polyommatus Iolas*, and *Clostera Anachoreta* in winter, the chrysalids having been kept in warm situations, whereby their development had been accelerated. He considered that by this means it might be possible to rear and perhaps naturalise some of the exotic species in this country.

The Chairman announced the publication of the sixth volume of Lacordaire's *Genera of Coleoptera*, devoted to the tribes of Weevils (*Rhynchophora*). Mr. Wallace announced an intended expedition, for zoological pursuits, to New Britain, New Ireland, &c., by Messrs. Wilson, of Adelaide. The second volume of Mr. Trimen's work on the Butterflies of South Africa, with a number of plates illustrating new species, was also announced as nearly ready for publication. Memoirs by Dr. Baly, containing descriptions of new species of Chrysomelidae, &c., by Dr. Stål, of Stockholm, containing descriptions of new genera and species of exotic Hemiptera, were read.

PROPOSED GARDENERS' BENEFIT SOCIETY.

IT is very strange, after the propositions to organise a Gardeners' Friendly Society by some of the leading practical gardeners of England, that they do not form a Committee at once, and carry it into operation. I am sure if they did so there are hundreds in this country who would be only too glad to embrace the opportunity of giving all the assistance in their power to co-operate with their friends on the other side of the channel. I only hope it will be taken up at once with energy, for such a Society as the one proposed would be second to none in the United Kingdom if once established. I hope all members of the profession will raise their voice in its favour, for it is a Society very much wanted—D. PHELAN, *Gardener, Rathmines Castle, near Dublin*.

I HAVE been pleased to see that some of our craft are anxious to form us and our employers into a Society for our mutual benefit, and I am as anxious as any one can be to set the "ball rolling."

I can count over fifty gardeners in regular places within three miles from here, and I think we could form a lodge or district for these, with Ashton as a centre, and other districts would be forming outside this. Manchester would form several districts; for near that city are some hundreds of gardeners, and in Liverpool the same.

Now I think we can set the Society going if some half-dozen men can be brought together to call a meeting—say in the anteroom of the Free Trade Hall, and request all gardeners and their employers belonging to Manchester district to attend, and the same in London, Liverpool, and other large centres.

I shall be most happy to meet at some convenient place any half-dozen or more gardeners to organise, first for a large meeting as suggested; and secondly, to prepare resolutions for the meeting to approve.

Details would have to be settled by a general Committee.

I have spoken to a goodly number of gardeners, and they all seem anxious we should form a Society. There are some things I shall strenuously oppose—such as having lodges at public-houses (though I am not a teetotaller); but these matters can be opposed if they appear.

My concluding advice is at the present, Let us gardeners be up and doing in the matter, and not standing listlessly by waiting for somebody to do it for us, remembering the old adage that "God helps those who help themselves."—JOHN HAGUE, *Gardener, Groby Lodge, Ashton-under-Lyne*.

GARDENING IN JAPAN.

WE have the pleasure of laying before our readers an interesting letter from Mr. Hogg. His many friends will be glad to learn that he is in the enjoyment of excellent health, and is industriously employed in exploring the country for rare and valuable plants, of which he has already gathered a very interesting collection. Some have

arrived in this country, and others are on the way. We are in the way of realising our expectations, that Mr. Hogg would very materially enrich our collections of ornamental and useful plants. If in doing this he could at the same time succeed in learning the Japanese the use of improved horticultural implements, and subdue some of their peculiar prejudices, he would be benefiting two nations at one and the same time:—

"Kanagawa, April 30th, 1863.

"MR. EDITOR,—Although much has been written extolling the climate of this country, my experience of it in the past winter confirms all that has been said regarding it. The change from living in a climate of at times almost arctic severity to one where the cold is just sufficient to bring about the delightful changes of the seasons, renders it a season of prolonged enjoyment, and really seems to add so many days to the span of life. In the northern and western parts of the country, where exposed to the cold blasts from Tartary, it is said to be much colder; but the ameliorating influences of the Pacific have a marked effect on the eastern coast. Since the heavy rains of October there has not been much wet weather until about a month past, and then not very continuous, and probably not more than necessary to sustain the growing crops in the porous soil of the country. The verdure of the growing crops gives a charming appearance to the landscape. The entire absence of fences between the fields gives a naturalness to the prospect that is, in a certain sense, delightful, but in another point of view does away with the idea of individual possession, so intimately associated in our minds with a homestead and personal prosperity. The yards surrounding the houses are usually enclosed with a rude hedge of *Cryptomeria*, *Retinospora*, *Althaea*, or some other strong-growing shrub. Their mode of trimming a hedge is very rough, and it is only occasionally that you see one at all neat and passable as a real hedge. I have never yet seen one clipped pyramidal.

"It seldom happens that there is sufficient frost to impede the working of the soil, and during the past winter not once; and there is no doubt it is owing to the fact of the frost not penetrating the soil to any considerable depth that so many plants that are hardy here prove too tender to withstand our climate. Very rarely ice is formed of sufficient thickness for skating. The soil is a deep, black, light loam, much resembling the soil frequently used for growing *Camellias* found in the ledges and at the base of rocks. Much has been said of its productiveness; but in this I think it is more owing to liquid-manuring continually applied than to any very great natural fertility. That this is the case is occasionally very apparent, by observing patches of grain in places where manuring has been neglected looking very stunted and yellow. These remarks apply only to the soil on the high lands, that in the numerous intervening valleys where Rice is grown producing large crops by irrigation alone. In places along the valleys, where the surface is too elevated for the purposes of irrigation, and yet too wet for growing cereals, a simple expedient is resorted to to bring it under culture for both, by laying it out in sections of the same width, about 30 feet, and convenient length, and then throwing the soil of every alternate section on the top of the adjoining one until of sufficient height. On the raised sections grain or vegetables are grown, and in the intermediate ones Rice. With you such lands are chiefly used as meadows for hay or grazing; but here, where little or no meat is used for food, every effort is used in raising grain for the support of the population.

"One drawback in gardening here is the want of proper native Grasses, in this respect resembling the Southern States. A lawn is a thing almost unknown, as I only know of one attempt in that direction within the limits of foreign residences. The Grass used is a native perennial one, but in the winter season turns entirely brown and loses its beauty. It is a very close, dwarf-growing species, and would be admirably adapted to the purpose were it to keep its colour the whole season. A former resident, lately returned, has brought with her a variety of our Grasses for the purpose as an experiment, and it is to be hoped some of them will prove successful, although I do not think the Japanese, with their love for miniature gardening, will appreciate them for some time to come.

"In common with the Chinese, all their notions of beauty seem to be in torturing into fantastic forms anything that will answer the purpose, making fish-ponds with miniature bridges a necessary accompaniment in every garden, rock-work, imitations of mountains, &c. In their way some of their designs are very pretty, and have a merit of their own not entirely to be condemned as a branch of art, and a pleasing appendage where it can be properly introduced. Of landscape-gardening, as understood with us, they seem to have no idea.

"At the present time the farmers are all busy preparing their Rice lands and sowing their seed-beds for transplanting. The labourers wade into the deep mud and bury the noxious weeds that have come up during the early spring by turning over the soil with a pronged hoe like your potato-hoe, when it is soon covered again by the water rising to the surface, rendering it level again. In one of my rambles I was witness of their mode of sowing the seed. The patches of land used for the purpose are prepared the same as the others, and the seed sown very thickly. After it is sown a man follows with a long-handled broom, like a birch-broom, and beats the surface until it becomes almost a liquid mass on the top. I was surprised to find the grain had all been sprouted until the roots had become an eighth of an inch long.

"Vegetable-gardening is yet in its infancy here; not that there is not quite a variety grown, but that they seem to have no appreciation of the advantages of prolonging the season of any particular kind by forcing, or cultivating earlier and later varieties, or successive sowings. Peas sown in the fall are now becoming plentiful; but when this crop is gone that is the end of them for the season. The same also with Lettuce, now entirely gone. Carrots have been very abundant and fine all the winter. Another vegetable they grow, called the *Dy-ku*—a name applied to all the Radish kind—is much used among themselves. Large quantities of it are dried or pickled for winter's provision. It is of the Radish kind, only very large, averaging 18 inches, and as large in diameter as the top end of a large Parsnip, not, however, tapering, but terminating abruptly. It is pure white, having somewhat of a turnip flavour also. Whether it has been introduced since the country has been opened to foreigners I am unable to say, but it is hardly possible that its culture would become so universal in so short a time, besides never having seen it previously, although it might have been introduced from Europe. The same might also be said of Tomatoes and Egg Plants, which I saw extensively cultivated in the neighbourhood of Yedo, both of very small size. Whether they are a portion of the seeds distributed at the time of Perry's expedition, or whether they have been cultivated for years past, is a question I am unable to determine. If they are, they have allowed them to sadly degenerate. The question might be asked 'What became of those seeds and others presented since? Were they diplomatically received with bows and thanks and then quietly cast aside, or really put to practical use?'

"The implements of husbandry are of the most primitive and simple description and few in number. The principal one is a large heavy grub-hoe, in common use for all purposes. It is either made of wood shod with iron, or in the better kind, the blade is made entirely of iron. The blade is usually about 15 inches long and 6 to 8 broad, having a short handle as in a common grub-hoe. It is an unwieldy implement, but answers pretty well in their light soil. The difficulty attending its use is, that the worker is continually treading-down the newly-turned soil. Until some bold innovator changes the custom of going barefoot, or at least wearing something more substantial than straw sandals, the advantages of a spade cannot be turned to practical account. They have an implement somewhat resembling a spade, having a long blade without any shoulders for resting the foot. For what particular purposes it is used I do not know. These, together with the pronged hoe, the sickle, a fanning-mill (consisting of a simple wheel in a box resembling the one in use with you), and an instrument like a small road-scraper, made of bamboo with an iron blade in front, and used for raising earth from deep trenches, are about all that are used. Gardeners have very neatly-made sieves either of bamboo or wire in addition to the above.—T. H."—(*American Horticulturist*).

CYCLAMEN CULTURE.

IN reply to "A COUNTRY CURATE," we recommend seedlings of *Cyclamen persicum* to be allowed to grow as long as they will without receiving any extra stimulant in the shape of more heat. Give them water so long as they continue to grow, keeping them on the shelf of your greenhouse; but when new leaves cease coming from the crown, the plants assuming a standstill aspect, turn the pots on their sides to make sure of their not being watered. Keep in the full sun until all the leaves are off, when they may be placed close together on a shelf in a cool part of the greenhouse. We do not advocate shaking them out of the soil and storing the bulbs in sand, certain as we are that it has a tendency to weaken the bulbs. We should not be surprised if the seedlings continued to grow on through the winter until the beginning of May next year, when you must gradually withhold water and have the bulbs thoroughly ripe by the beginning of June, the pots then to be set aside in a cool place without water until the end of August.

At that time pot the plants singly, choosing pots about twice the diameter of the bulbs. Drain well; at least one-third of the depth of the pot should be filled with broken pots or sifted ashes, covered with a thin layer of sphagnum moss or cocoa-nut fibre. Use a compost formed of equal parts of turfy sandy loam and leaf mould, with a sprinkling of silver sand.

The bottom of the bulb should do little more than rest on the soil, and not be buried beneath it; but the crown of the bulb ought to be level with the rim of the pot, its bottom just within the soil, which leaves room for watering. Water sparingly until the growth commences, and as it increases give more water. Place in a light and airy situation, for if kept in a close, damp, or dark place they will never flower.

In after-seasons when the plants die down turn them into the open border of the garden, allowing them to remain until the nights begin to be chilly toward the end of September, when leaves very often are appearing and flowers rising. Pot forthwith, place on a shelf in the greenhouse, and you will have *Cyclamen persicum* in bloom all winter. Yours, however, may be the evergreen variety, by no means so rare as is represented, and if so, you will pot in August of each year and have flowers all the year round; but if evergreen they need a rest, and that is done by giving less water from June until September.

Having thus answered the inquiries of our correspondent, we will add a little information about various kinds of this favourite genus of "plants with the petals combed back," as a lady described them.

"The origin of *Cyclamen Atkinsi* is thus explained to us:— "After many ineffectual attempts," writes Mr. Atkins, "to produce a good cross between *Cyclamen comm* or *C. vernum*, and *C. persicum*, combining the neat habit of the two former with the colour and larger petals of the latter, having at the same time the foliage dark, yet relieved with a lighter band, or marbled, I at length succeeded in raising

the hybrid now figured, from seeds produced by a variety of *C. comm* impregnated with *C. persicum*, and this, I have every reason to believe, I shall be able to perpetuate, and thus introduce a new and most interesting feature into this beautiful family of plants. Amongst the seedlings, it was found that every plant deviating in the marking of the foliage from the seed-bearing parent, produced white or bluish flowers, whilst those retaining its plain dark leaf have invariably bloomed with different shades of the colour of that species."

"This account of its origin perfectly explains its appearance, it being, in fact, exactly intermediate between its parents as to size and form, and to some extent even in colour. The specimen which our vignette represents was exhibited with about seventy fully-expanded flowers, and bears full evidence of the success of Mr. Atkins' mode of culture."

"In *Cyclamen Atkinsi* the leaves are large (2½ by 2 inches), ovate obtuse, cordate at the base, with a deep sinus, the sides of which overlap, dark glossy green, with an irregular pale zone within the margin; the under surface is liver-coloured, or dull purple. The flowers are elevated on longish verrucose stalks, and are of a French white, marked with

a deep crimson ovate blotch at the base of each segment; the calyx consists of five acute lance-shaped pubescent segments; the corolla has a short globose tube, and a limb of five broadly obovate segments nearly seven-eighths of an inch long; the mouth of the tube is nearly circular, the angles being indistinct; the stamens are included, but the style equals the tube. The flowers are scentless.

"*Cyclamen ibericum* produces flat heart-shaped leaves, having an open sinus, and the margin very slightly sinuate-dentate or entire; they are deep

green, with an irregular heart-shaped belt of pale greyish-green some distance within the margin, the veins sunken on the upper face, prominent and green beneath, on a dull reddish-purple ground. The flowers vary in colour; in some, they are pale rosy or flesh-coloured, in other plants, deep rose-colour; in some they are white; but in all cases they are marked with a broad ovate spot at the base of the segments, which spot is either purple or crimson, and is extended in the centre as far as the mouth, which, in the front view, thus shows five purple bars or spots; the bases of the segments are curved outwards at the margin, the mouth thus becoming pentangular, with concave sides. The calyx lobes are acutely lance-shaped; the tube of the corolla is ventricose, the segments of the limb either roundish obovate or oblong obovate. The stamens are quite enclosed, and are slightly exceeded by the blunt, simple stigma, which is somewhat exserted."—(M., in *Garden Companion*.)

THE LATE FROSTS.—As I see the frost has been so general in England, I give you a short account of what it has been in Ireland. We had some very cold nights from the 18th to

Cyclamen Atkinsi.

the 26th of July. On the last-mentioned date the Potatoes were severely injured in low grounds. I notice that there is always an interval of four or five days between England and Ireland, so that when we hear of bad weather in England we may prepare for it here in a short time.—E. WELCH, *Palace Garden, Armagh.*

AMARANTHUS MELANCHOLICUS RUBER CULTURE.

HAPPENING the other day to take up a copy of your valuable paper, dated August 11th, I came upon the following remark respecting the new plant named at the head of this letter:—"It requires peculiar management, or you will fail with it. Sow in heat not later than the end of January," &c. The thought came into my mind that it is much to be regretted with that gardeners each believes that his own way of proceeding is the only correct one. They will not understand that there are several ways of doing the same thing.

"But what has this to do with the *Amaranthus*?" perhaps you will be inclined to ask. Why, just this. I have been a very successful grower of it this year, and yet I never did anything that the writer of the above extract declares to be necessary.

I heard of the plant, and sent for a shilling's worth of seed from Messrs. Veitch. On its arrival I thought I had very little for my money, and so I set to work to count my seeds, and I found that I had 115, each about the size of a grain of gunpowder. This was at the beginning of April.

Now, I do not possess a frame, and, therefore, sowing in heat is not in my line; but I raised it in the same way that I do many other plants. On the 10th of April I sowed the seed in a shallow box, and put a piece of glass over it. This box I placed on my kitchen-window seat, and as my kitchen is a warm one, the seeds soon germinated. At first I had about ninety plants, but some beetles destroyed a few by finding their way beneath the glass.

As soon as the plants were through the soil the box was placed in an orchard-house, which, being always open, is not so warm as a cold frame. When the nights were cold I carried the box in-doors. In this way the plants soon began to grow. I then pricked them out in small boxes, and placed them in the border in the beginning of June. They did not not make much progress at first, but towards the end of July they grew rapidly, and the best of them are now 15 inches high. They have grown very evenly, and are very effective in the garden.

I have written this just to show that a great deal may be done with very small means, and with a hope that I may encourage others to follow my example.—W. M. A.

STRAWBERRY CULTURE.

VARIED has been the information we have received by the late discussion in these pages upon the cultivation of the Strawberry; but before the subject shall be again shelved for a season I wish to detail a little experiment I made lately, not wishing to attach to the same any very great merit, though it would seem rather original.

Having come to a determination about midwinter, some two years ago, to entirely renew a fruit-border we have here at the base of the north wall—in which, in fact, are the fruit trees and also four rows of Strawberries, which we depend upon for our latest out-door picking—I was at a loss how to proceed with the Strawberry plants, as we had not prepared any younger ones to place in their stead. At last I came to the conclusion to try the removal of the plants, each with a good ball, from the old to the fresh-made border as we proceeded with each fresh trench. Fortunately the soil they were in was a tolerably good stiff loam; this aided materially in the removal, for after having formed a very slight hollow upon the surface of the fresh-made soil, we removed each plant separately with the spade, taking care to press it down firmly, and yet not to bury the crown too deeply.

I am pleased to say that last year and especially this, though our crop of Strawberries was exceedingly good, yet

none were better or fruited more abundantly than did those we removed, whilst the plants at the present time look exceedingly vigorous and healthy.

Thus, may it not be possible that, with the view of securing a greater amount of fruit from a certain piece of ground, it may at times be advantageous—(especially when, after three years' planting or so, the plants, though still looking luxuriant and well, may be supposed to have impoverished the ground below too much to render it probable that a good crop of fruit can be secured in the following season)—to keep the old plants with their strong healthy crowns in preference to chopping them up and throwing them away to make room for young ones? Where practicable, a continuous picking of fruit may be thus insured from the same plant for five years at the very least; and by adopting the system we would be independent of the trouble of procuring suckers and planting every three years. We always pick-off the first season's flowers, leaving but four years of real fruiting out of every six.—W. EARLEY.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, see that the beds are kept free from weeds. *Artichokes*, cut down the flower-stems, and remove the dead leaves from the old plantations; those made last season will probably now produce a few heads. *Cabbage*, continue to plant-out for Coleworts at every favourable opportunity. Prick-out the young plants intended for the main spring crop. Sow, also, largely of the most approved sorts, for standing over the winter in nursery-beds. *Cauliflowers*, sow the principal crop for keeping over the winter. *Dwarf Kidney Beans*, give them an abundant supply of water if the weather continue dry and hot when they are in bloom, or most of it will drop off prematurely. *Endive*, tie-up, and also Lettuce, to blanch. *Leeks*, plant-out the thinnings of the seed-beds as soon as the weather is favourable. *Onions*, pay due attention to this crop, let them be removed from the soil as soon as they have ceased to grow; if left longer than this they frequently get mouldy, and do not keep so well. Let them be spread out in dry sheds till fit for tying in ropes. *Turnips*, the last crop for this season should be sown as soon as the weather is favourable for that purpose. Thin the advancing crops. *Vegetable Marrows*, keep the plants well supplied with water during dry weather; cover the ground about them with short grass or litter of any kind. At the earliest opportunity earth-up the Broccoli, Savoys, and all other crops that require it. Remove Peas that are mildewed immediately they are done with. Destroy caterpillars that infest the Brassica tribe before they do much mischief.

FLOWER GARDEN.

Keep the herbaceous plants neatly tied up, and cut-off the flower-stems of any that are becoming unsightly. Decay of some of the earlier flowers will now begin to leave blanks which will not be easily filled up unless a stock of large things in pots has been provided. In mixed borders some of the late kinds of Phloxes, Asters, &c., may occasionally be untied, and made to occupy three or more sticks in order to fill the blanks. Petunias and other bedding plants of rambling habits to have a pruning betimes to keep them within bounds. A few Crocuses, Snowdrops, &c., may be planted soon to obtain an early bloom. There is no grower who is in the least degree conversant with the cultivation of the Rose, but knows that an abundant supply of stimulating materials should be applied to the autumnal-flowering varieties to have them in perfection during the next two months. Without applying manure water in large quantities there will be nothing but disappointment this season: we would, therefore, urge the necessity of stirring the soil about the roots of the Noisette, China, Tea-scented China, Bourbon, and Perpetual varieties, and when this operation is finished giving the trees a good soaking with manure water; an abundant, strong, and healthy bloom will be the reward, and the plants themselves will continue for a greater number of years to throw up continually an abundant supply of bloom. If you have any spare ground sow some of the North American annuals—Clarkias, Nemophilas, and Collinsias are amongst the number, the seeds of which never

vegetate so readily as when recently gathered. Candytuft will also do to be sown now. Continue to plant-out Pinks as they strike root, bearing in mind that those which are put out now in the place that they are to flower in next season generally lace much better than those planted in the spring. Propagation of all the more important bedding plants should now be pushed on as quickly as possible: late-struck cuttings, as has often been remarked, are difficult to keep through the winter on account of not having a sufficient amount of roots and well-ripened wood. When the Scarlet and other Geraniums are struck in the open ground they should be taken up and potted as soon as they have made roots; they will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure to harden them for the winter. While propagation is proceeding attention must be turned to the amount of winter accommodation, which, whether in the shape of frames, pits, or large structures, should be in readiness to receive the stock before bad weather sets in. Though more expensive in the first place, a series of brick pits from 5 to 8 feet wide will be the cheapest in the end, and if heated by running a four-inch pipe around them, mats may be dispensed with. Pits of this class would be also valuable during the summer for a variety of purposes.

FRUIT GARDEN.

The earliest Apples and Pears are to be gathered as they ripen. Early fruit more especially is the better for being gathered a few days before it ripens on the tree, as in the latter case it usually turns mealy directly. As Peaches and Nectarines now begin to ripen, it will be advisable to fix nets or mats to catch the falling fruit. A double row of stakes 3 feet long may be driven into the ground about a foot deep at about 3 feet apart, one row close to the wall, the other about 2 feet from it, and the nets or mats tied to the top of the stakes so loosely as to form an open bag. In this may be laid loosely a little moss, dry grass, or any other soft material; for fruit is at all times best gathered by hand, but after the strictest attention some will fall, and if something is not provided to catch them they will be bruised and spoiled.

STOVE.

The principal object should be to ripen the shoots by exposure to sunlight before the approach of winter. It is a great error to keep plants that are required to produce a profusion of bloom during the following spring and summer actively at work late in the autumn; summer is the season when rapid development should be promoted, and autumn the period when the young wood should be completely hardened and ripened preparatory to the approach of winter. *Gesnera zebrina* to be looked after, and shifted into a compost of equal parts of fibrous loam, heath soil, and leaf mould. *Euphorbia jacquiniiflora* should now meet with every encouragement.

GREENHOUSE AND CONSERVATORY.

Continue to look over climbers, borders, &c. Large specimens which have been placed out of doors to make room for other things will soon require housing; this, however, will depend greatly on the weather. Look well after late-flowering things. Late *Heliotropes*, Scarlet Geraniums, *Petunias*, &c., will now be somewhat pot-bound, and will in that state, with the application of weak liquid manure, produce abundance of blossom on a light shelf until the beginning of December. The usual quantity for a season's supply of the kinds of soil used in potting should be laid in as soon as convenient, and before the ground be sodden with the autumn rains; for even turfy soil should not be carted out and stacked up when saturated with water. The management of the conservatory will be more uniform now than in summer, no syringing will be necessary unless for a plant here and there which may require it for keeping down insects. Let all the watering be done in the morning, and give no more of it to any stove plants which are brought into this house for their bloom than just enough to keep them from flagging.

COLD PITS.

Young stock, intended to flower next season, to be exposed to the midday sun in order to ripen the wood, taking care not to do this so rashly as to injure the foliage. It is advisable after this season to be anticipating the approach

of winter, and to use every possible means to forward the growth of valuable hardwooded plants in order to have the wood firm and able to resist damp, &c., as soon as possible, and this is especially necessary where the plants have to be wintered in these structures. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WE have had a few slight showers that just refreshed the foliage a little, but which were raised from the ground by evaporation in a few minutes, and did nothing to speak of for our tanks and reservoirs. Did what we could to prevent crops suffering; but, with the little liquid at our command, could not keep Pea bloom from shrivelling and that of Scarlet Runners from dropping, though even these we hope to overtake in a day or two with sewage water. Sowed what we think will be about our last crop of Turnips, with Radishes between the rows, draining the drills and waiting for a shower slightly to damp them, or doing so with the rose of a watering-pot, so as to moisten the seeds. There is every appearance that there will be plenty of rain ere long. Planted-out Lettuces, Cauliflowers, and Endive, watering merely at the roots and shading. Sowed Lettuces, Cauliflowers, &c., for the first spring crop—merely a little of the latter. Thinned Turnips, Radishes, &c. Pretty well finished getting up Potatoes, which on the whole have been good, and noticed only one or two traces of disease. The kinds were all early ones and with small tops, so as to admit of close-cropping. Pulled up Pea-haulm when pretty well done with, and will have the ground dug and rough-trenched for the last sowing of Onions and Spinach. Gathered most of the pickling Cucumbers, and will now care little about them. We did so badly with them out of doors last year that we placed a frame over them this season. The lights were left down whenever there was a chance of a shower, and now we want the frames for other purposes, so that the Cucumbers may do as they like.

Cucumber Disease.—We have been more or less troubled with the Cucumber disease for three years. This season it did not trouble us until about the end of June. We find there are no means of mastering it like young plants and frequent planting. We have tried change of temperature, change as to quantity of air, change of soil, from common garden soil up to peat; and now we find there is nothing that will keep it away after it has once made its appearance, though plenty of air and light, and not too much heat, and comparative dryness rather than wetness, will always lessen its violence. Nothing could do better than our Cucumbers in the early spring and early summer months. The results of two seasons convince us that if the disease makes its appearance there is little security afterwards, except in frequent planting. We have a strong opinion that whilst plants in airy houses—span-roofed, &c., with plenty of light all round them—will thoroughly escape, those in frames and low pits are apt to be seized. The most wonderful thing is that, from our own observation and experience, the disease will appear in one garden and it will not appear in a second where much the same mode of culture is adopted, even though there may be only a short distance between them, and then very likely the second garden will have it the following season and the first will escape altogether. Whenever the brown spot appears on the leaf, we know of no means of thoroughly eradicating it. A fruit or two may be slightly gummied, and yet the main crop be all right; but whenever such an appearance is observed, the fruit should either be taken away or else the gum rubbed off, and the place dusted with sulphur and charcoal dust. On the whole, then, when the disease manifests itself we have no remedies as to cure; but as to avoiding its presence we have no preventives equal to fresh air, fresh soil, using sulphur on the walls, a little clear soot or other manure water instead of manure of any kind in the soil, plenty of light if that should be subdued in the middle of the day, and rather frequent planting. If ever a spot shows itself it is wise to sow in another place or take cuttings from a healthy plant, but sowing is the surest.

Planted out strong plants in a pit for autumn supply, which, like the crop just bearing, are doing well; but there

is seldom any difficulty with the plants at first. We have sometimes had fine crops from plants approaching two years old, and we confess we are nonplussed to find how we cannot now carry the spring plants right on into the autumn. We seldom grow Cucumbers all through the winter now; but those who contemplate doing so should take their seedlings up without delay, pot them separately, and when planted out keep them nipped in pretty well, and allow no fruit to remain until the plants are strong and well furnished with good healthy foliage. Such plants, if wanted to produce abundantly in December and January and onwards, should not be allowed to do much to distress themselves until December. For such purpose a span-roofed house or a steep narrow lean-to, is far superior to a low pit, though the expense for fuel will be greater; and with a bottom heat of about 80°, or from that to 75°, the top heat may fall to 60° at night, and the plants will do better at that in the dark days than if the temperature were higher.

MUSHROOM-BEDS.

Put the first little piece in the Mushroom-house. We were pleased to find that one of the best gardeners of the day, and who must have Mushrooms every day, adopts the plan we follow, of making little bits of beds constantly. By thus doing merely a few yards at a time there is less chance of failure; but when a large bed is made, and any casualty occurs, then, of course, the disappointment is proportionately large. For these small, shallow beds in-doors, nothing excels horse-droppings moderately dried, with a good proportion of short litter in it, and some good turfy loam, or scrapings and parings from the highway. We are always scarce of droppings, but we have just thrown a heap of materials together, which we are sure when slightly heated will make a first-rate article—such as two small loads of rather moist somewhat-spent dung, a good portion of which was horse-droppings, one load of fresh horse-droppings, one load of short dry litter, such as pigs will roll in under a shed, and from one to two loads of dry turf cut small, and road parings and scrapings. These were well mixed and thrown into a conical heap to ferment a little, and were covered with 4 inches of dry litter from the stable to hasten the fermenting process, and to keep wet and wind out. In a few days that heap will be in a nice condition for making shallow beds of from 12 to 16 inches deep. Of course, it would do equally well for larger beds, either in sheds or in the open air; but out of doors, as a large bed must be made for winter use, the materials need not be so nice. If the dung is prepared much as in our younger days we used to work it for Cucumbers and Melons, it will answer admirably, if well wrought, nice and moist, and sweet throughout. Such beds out of doors are best made in the form of a ridge or span-roof; the base, say, 3½ feet wide, rising to 3 feet at the point in the centre, the dung being laid on in layers, and firmly beat downwards and from the sides as the work proceeds. When the heat declines to about 80°, the sides should be spawned, and if the temperature continues all right then earth-up. Before performing the latter process, we used to put a layer of fresh droppings all over the bed, if even less than an inch thick, to feed the Mushrooms as it were. The soil we like best is rather stiff loam, from 1½ to 2 inches thick, well kneaded, and then beaten to a smooth surface. Such beds need covering at once to protect them from the weather, and the covering must be thick or thin according to the weather. The beds will do best when the heat in the dung will range about 70°, and the surface of the bed range from 55° to 60°. We have known beds suddenly exhaust themselves from overheating when the covering was not lessened in warm muggy weather in winter. If such a bed can be made in a shed, either as a lean-to or a ridge as above, it will be a great advantage in the way of covering, as rains and snows will be excluded. Such beds will often produce largely for many months, but for a continuous supply, where a little heat can be secured in winter, shallow beds are the most sure. Now is the time to prepare materials for these large beds, and for shallow ones too, in the case of those who want Mushrooms chiefly in winter.

SPAWN-MAKING.

We have just commenced making a bit. A few barrow-loads of fresh horse-droppings are collected, and then as

much cowdung, fresh, as when mixed and blended together will look like stiff mortar or grafting-clay. This, then, is squeezed into a mould of four pieces of wood, the same as that used for making bricks, and each brick of dung is placed as turned out on a board to dry, two holes being made in each for inserting the spawn when dry enough. Then it will be placed in a heap and covered with litter to cause the spawn to run. The gentleman referred to above suggests an improvement, which we think a very good one—namely, making the bricks of the length and width, but only about half the thickness of the common building-bricks. We can easily see that the pieces will dry quicker, and then that the spawn will sooner permeate or leaven the mass. We are just a little doubtful if these thin bricks will keep quite as long. Many use no mould whatever, spread the material on a hard bottom, beat it well, and then cut it out in the sizes that please them, with a clean sharp edging-iron. However managed, good spawn is an essential element of success, and the care that is exercised in this respect is fast causing the Mushrooms of our pastures to be tabooed for everything except ketchup.

FRUIT GARDEN.

Looked over late Melons to set the blooms. Gathered Peaches and Nectarines which come in orchard-house as fast as we need them. Have still a few Apricots out of doors not ripe, which shows how cold we are. Nipped the points of low standard Apple and Pear trees—that is, the young growth after the first stopping. Thinned Pears on such small trees, but still not nearly enough. Have been advised to try the pigs with them, but doubt if they will care for them now, though they would feast on them when ripe. Syringing in orchard-house because we are scarce of water. Plums are coming in from pots, but not evenly as respects the same kinds, as we observe that one Jefferson's has given us two dishes, with a great draught of air on night and day, and a lot more ripening nicely, whilst the same kind in a warmer place is still hard as bullets. Gave manure water to Strawberries in pots. The Victoria Plum in the latter place is also yet hard, though taking on its usual colour. Green Gages have ripened well. Have a little tree named so, but which, no doubt, from its lateness is Reine Claude de Bavay. Have not yet cleaned the Strawberry-quarters, but have picked out a number of the best runners we could find, and pricked them out on a rich border about 5 inches apart, the richness being confined to a few inches near the surface, and they most likely will be raised for forcing in March and April. At that time such plants with good large balls and firmly potted will answer well; but such a system would be of no use for obtaining Strawberries in February or March, or even the beginning of April. For such work the plants must be well established, and the buds ripened in the pots in which they are to fruit before the autumn.

ORNAMENTAL DEPARTMENT.

Potted lots of Primulas, Cinerarias, &c., for winter. Gave full light and air to Epacris to ripen wood and buds, ditto as to early-flowering Heaths. Deferred potting Poinsettias, Euphorbias, &c.—one small shift—for want of suitable pots. Fresh regulated conservatory, supplying with Fuchsias and varieties of Geraniums, and made tidy flower-beds out of doors. Find to our mortification that the dryness is making havoc with the Grandiflora Double Feverfew in the ribbon-borders. It was so strong we were obliged to bend it a little; but the flowers are turning dark, and not enough of fresh ones coming to keep up the mass. Believe it would have been all right if we could have watered, as it did well in other places last year up to the end of the season. However, we should be tempted not to trust it in the post of honour next season. A large single white Chrysanthemum, which we call a Chinese Daisy, would have defied all weathers unless there had been the dryness of the desert. The Feverfew may in a fortnight be all right again; but, if not, we can make the neighbouring rows fill up the space, and bury it out of sight if we like. Everything else has stood the dryness better than we could have expected.

Have commenced propagating for next season, and will now have a fortnight or three weeks of it. We wish we had a reserve-ground for plants for cuttings, we do so dislike breaking in on the flower-beds; but we cannot help ourselves. In most essentials the plans described by Mr.

Thomson are much the same as we adopt, with modifications according to circumstances. Our chief requisites are fresh sandy loam from the roadsides, or made so by the addition of road drift if we can obtain it, or other sand if not, and a sprinkling of silver sand for the surface. We make little difference whether we prick out the cuttings at once into frames, pits, small moveable boxes, or pots, large or small—we strike in all ways. We have commenced with Verbenas, and these chiefly white, scarlet, and purple. In taking them off we select nice stubby side shoots, and although there is more time taken at the bed, there is much less required at the potting-shed, and a lot of cuttings may be taken without at all disfiguring the bed. We prefer taking Verbenas first, because in September, though it is time enough to strike them, they are often liable to be attacked with thrips, and it is difficult to destroy it. Even now, when the small cuttings are made, we pull as many as we can hold in the thumb and three fingers through tobacco or sulphur water, and let them lie a short time on the bench before inserting them. This season, 60-sized small pots being most handy, we have used them for the first batch, placing a few crocks in the bottom of the pot, filling nearly up with the sandy soil, pressing down with a round board, and placing a little sand on the surface. These pots, a little more than 3 inches in diameter inside, hold about twenty cuttings. They will be placed on ashes or sand on the ground with a frame over them, as we dislike artificial heat if it can be avoided. One advantage of having them in such pots is, that if anything in the way of insects gets on them they can be laid on their broadsides and cleaned with the syringe. When we follow this plan we generally move the cuttings into a larger-sized pot in January or February, and head them across for cuttings ever so often. We never find room to single pot any, and we like spring-struck plants best. We will follow as fast as we can with Heliotropes, Anagallis, &c., and then with Scarlet Geraniums, and in October we will look out for Calceolarias, or perhaps a few in the end of September. Rolled the lawn and switched with our daisy-knife, as it is too bare for machine or scythe.—R. F.

TRADE CATALOGUES RECEIVED.

W. Cutbush & Son, Highgate.—*Bulb Catalogue for 1863.*
William Paul, Waltham Cross.—*Select List of Hyacinths, Early Tulips, Gladioli, and other Bulbs.* 1863.
B. S. Williams, Paradise and Victoria Nurseries, Holloway.—*General Bulb and Fruit Tree Catalogue.* 1863.

COVENT GARDEN MARKET.—AUGUST 24.

There is an abundance of every kind of vegetables. Peas are now or very nearly over, but a few parcels are still to be had. There is no scarcity of Grapes and Pine Apples, and of Melons there is an abundance. Filberts are plentiful. Potatoes are plentiful. Regents, 80s. to 100s.; Shaws, 60s. to 80s. per ton.

TO CORRESPONDENTS.

POPULAR OF RAPID GROWTH, &c. (M. A. B.).—We fear that your "green fly" is the thrips, but in either case fill the pit with tobacco smoke, covering the lights to keep it in. Do this two nights in succession, shading from bright sun. The leaves should be dry at the time of smoking, but a sprinkling of water over the foliage in the morning after the operation will help to destroy the pests. The Black Italian Poplar is a rapid grower, and so is the Balsam, but no Poplar grows so fast as the Ontario. Unless your garden is wet they will not thrive long. We live in a smoky atmosphere, and are dreadfully pestered with windows that, like eyes, are continually upon us, and in order to shut-out these we made a plantation of Italian Balsam and Ontario Poplars, with a sufficiency of Limes and Elms. The Poplars from 12 feet at the time of planting attained a height of 25 feet in five years; but they are now dying at the top, and will soon give place to the Limes and Elms, which are better able to stand the smoky air of towns than Poplars, which like moisture above as well as below. Lombardy, Abele, and Aspen stand smoke better than any Poplar we have tried. We would plant a row of Black Italian as large as we could procure them, and a row of Limes in front, so that by the time that the Poplars are dying the Limes will be ready to take their place. You will not be able to procure Poplars we fear 30 feet high in any nursery; at least, we do not know of any place where they may be had. Such extra-sized trees are best found by visiting some large nursery, or by inserting an advertisement in a gardening journal.

COCOANUT FIBRE DUST (D. H. C.).—Light fresh loam should be mixed with the dust for potting. Two measures of loam to one measure of the dust.

DOUBLE-FLOWERING PEACHES BECOMING SINGLE (E. O. B.).—A very likely cause of your Peach blossoms becoming single and bearing fruit is, that the soil in which the tree is growing is too poor and light, and the south exposure may have something to do with it, a double flower being simply one in which stamens and pistils are exchanged for petals; and, therefore, if your Peach lacks nourishment at the root, and is exposed to a hot sun, the tendency to single flowers and fruitfulness is sure to be the result. Many of our double-flowering bulbs—such, for instance, as Narcissus—become single when grown for a length of time in a poor dry soil. Try what partially lifting your Peach and substituting very rich soil will do for the continuance of double flowers.

LIQUID MANURE FOR ROSES (Idem).—The frequency and quantity of liquid manure applied to your Roses must be entirely guided by circumstances. 1. they are growing in a poor gravelly soil from which water soon drains away, you may for the next month, if the weather be dry, apply it every day in a weak state. It is, however, better to give a good soaking at intervals, and much the surface of the soil to prevent evaporation. If your Roses are in a strong adhesive loam, the applications of liquid manure will, of course, not be so much required. We always prefer frequent applications in a weak state to stronger ones at longer intervals.

HEADING-BACK AFTER BUDDING (Idem).—No doubt the bending of the shoots will to some extent check the flow of sap to the point of the shoot and throw it back upon the bud. We would, however, prefer shortening the growth in the usual way. The time and attention required to remove the lateral shoots will be very trifling, and will not be so great as would be required in heading the shoots at first.

WHITE LILIES—BRUGMANZIA ARBOREA NOT FLOWERING (M. F.).—The term "White Lilies" is so perplexing an appellation that we are rather at a loss to know exactly to what plant our correspondent refers. It would save a deal of perplexity if in asking for such information more particulars were afforded, and if the proper botanic names were given to plants instead of the popular ones of which, in many cases, this being one of them, the same name is applied to several. We, however, inspect from our correspondent's having basins of water formed round the Lilies that they are Water Lilies. It is not very easy to determine what may have been the cause of their flowering weakly. We have always observed that the common *Nymphaea alba* and *lutea* have always thriven with the greatest luxuriance in clayey soils—i.e., in pieces of water where the bottom has been of clay, and if the Lilies in this case are in a light material, we would recommend that soil of a heavy nature be substituted. They are not generally shy in flowering, and, perhaps, this may not be the cause. Perhaps by some means the foliage may have been prematurely destroyed, and that would affect their flowering and cause them to be altogether in a weaker state. If the wood of your *Brugmansias* is, as you state, good, perhaps a little more time may cause them to be productive of flowers as well as your neighbour's, who may, perhaps, have started his plants into growth earlier than yours, or may, perhaps, have kept them a little warmer. Generally they are very sure in blooming, and if yours do not flower this autumn it would be difficult to say what has been the cause. The only way that you are likely to cause them to flower is to keep them healthy by a plentiful supply of water when they require it, not to keep them in the shade of other plants—such as climbers or Vines, and to keep the foliage free from red spider, to which they are often subject. If they have made as good wood as usual, it is not too much to hope that they will flower this autumn yet. We have grown excellent flowering plants of this *Brugmansia* from cuttings struck early in spring and grown on quickly and exposed to plenty of light in stove heat. By September they make fine strong plants in ten-inch pots, in which if well supplied with water they form very handsome plants, bearing plenty of flowers, and few plants are more picturesque and beautiful.

ARCTOTIS RUPESTRIS AND DIANTHUS HYBRIDUS MULTIFLORUS.—PROPAGATING ALYSSUM SAXATILE VARIEGATUM (Mrs. W.).—The two former of these should prove handy in your climate. The Alyssum is usually one of the most easy plants to propagate. The quickest and probably the surest way of striking it at this season is to well drain a pot or seed-pan, or even a wooden box, then fill up to within 2 inches of the rim with soil composed of half loam and half leaf mould, and fill up with the same compost and sand in equal proportions, sifted fine for the insertion of the cuttings. In selecting the cuttings take the stubby side shoots that have not yielded blooms, and after being prepared in the usual way insert them about half an inch apart in the pots or pans, and place them in a pit or frame in which there is not much artificial heat, where it kept close and shaded they will root, at least they invariably do so under our care.

SEEDLING TROPEOLUM (Banyard & Son).—Your seedling is not unusual. We have seen it in several places this season, and we doubt very much if it possesses sufficient merit to warrant you in distinguishing it by any particular name.

SEEDLING CARNATIONS AND PICOTEES (Mrs. Levett).—They are very bright-coloured and pretty, and will render a border gay, but they do not possess the characteristics required by florists. We have had several similar boxes of specimens raised from seed bought of Messrs. Carter.

CALCEOLARIA (C. D., Westmeath).—As far as we can judge your plant is *Calceolaria Aurea floribunda*, but if you act wisely you will not depend on the mildness of the last winter as any security for the plant living out in the winter that is to come. You had better take cuttings in the end of September.

SCARLET GYM MELON CRACKING (W. A. Blake).—Your Melons crack because you give them too much water when they ought to be ripening. After a Melon begins to net it needs no water beyond that necessary to keep the leaves from flagging. After so much bright weather as we have had lately a great many Melons have cracked, for the simple reason that bright sun tends to early maturity; under it the rind of the Melon becomes hard, and when cloudy weather sets in the Vines grow more freely, impelling more matter into the fruit, which being rendered hide or rind-bound by the influence of hot sun refuses to expand, and literally cracks to make way for the increased amount of nourishment driven into them. It is hopeless to expect such Melons to swell any more after a month of bright sunshine; therefore, the atmosphere should be kept dry, and less water by half given in dull than in sunny weather. The Melon requires as much water as a Cucumber from the time of setting until it begins to net, and after that it can hardly have too little. Our Scarlet Gems this year are smaller than common, but exquisite in flavour. Keep the atmosphere of your frame dry by leaving a touch of air on all night, and give no more water at the root.

IPOMÆA LEARI (J. Knottley).—Both plants may be correct, for the leaves vary in form. There is a coloured portrait of the plant in Paxton's "Magazine of Botany," vi., 267; and in the description there given, it is said—"Leaves variable, most frequently cordate (like your small leaves), but often unequally, and sometimes distinctly three-lobed" (like your large leaf).

No. 51 (N. D.).—This Number is out of print. Our correspondent wishes to know the direction of Mr. Henderson, lately gardener at Dunkeld, as in our correspondent's neighbourhood directions how to fill Mr. Henderson's "Patent Broom-head" are much desired.

WALNUT TREE UNHEALTHY (E. C. T.).—Had it been the blossom only of your Walnut tree that dropped at the end of May, we should have said that it was occasioned by the frosts we generally have in that month, and to which last May was not an exception. But when you tell us the leaves also fall and the shoots are decaying, there is no doubt but that the roots have got into bad soil. It is not the horizontal roots you must examine, but those that go down vertically into the ground, and for this purpose you must search right in under the trunk.

INSECTS ATTACKING LETTUCE AND BEET (H. Benecke).—The insects at the root of the Lettuce are a species of aphides (*A. Lactuceæ*). Their extirpation is attended with great difficulty from their underground habits. If the earth be carefully moved round the crown of the plants and then lime-water introduced, it would, probably, be successful. The Beet leaves are infected with the ruminating larvae of the *Anthomyia Beteæ*, a two-winged fly very like the common house fly. We can only recommend pinching the leaves in the infected parts when the grubs are at work, or if the leaves are badly infected they should be pulled off and burnt. This will prevent the subsequent broods which succeed each other very rapidly.

INDIAN CORN (Ler.).—You would most likely obtain the kind you name by applying to any of our agricultural seedsmen. If they cannot supply you we do not know who can. It is not our practice to recommend one trader in preference to another.

BOUQUET (Miss Landon).—We regret that we cannot deviate even in your case from our rule of not replying privately to questions that may be put to us, nor do we suggest arrangements for adoption, though willing to give our opinion on those which are submitted to our inspection.

GERANIUM CLOTH OF GOLD.—A *North Briton* having read in Mr. Adey's remarks on bedding-out at the Crystal Palace, that this variety is easily propagated by leaves, will be obliged by Mr. Adey's informing him how and when the leaves are put in.

NAMES OF FRUIT (F. H. A.).—Your Apple is the Belle de. (*R. J., Manchester*).—Your Grape is Muscat of Alexandria. (*W. W.*).—We regret we cannot name fruit in such an immature state as those are that you have sent.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*A. B.*).—Your *Feros* are—1, *Cheilanthes Dicksoniana*; 2, *Nothochlæna distans*; 3 and 4 appear to be small bits from *Lastrea cristata*, the Crested Fern; 5, *Lastrea dilatata*, broad prickly-toothed Fern; 6, *Polystichum angulare*, the angular or soft Prickly-shield Fern. (*J. C.*).—*Rhus* continous, a deciduous hardy shrub about 6 feet high. (*J. A.*)—1, *Doodia media*; 2, *Doodia caudata*; 3, *Pilea muscosa*; 4, *Nothochlæna lanuginosa*; 5, *Centradenia rosea*; 6, *Coleus Verschaffeltii*. (*C. P.*).—*Pteris heterophylla*, or Various-leaved Fern. (*F. C.*).—*Kölreuteria paniculata*. (*H. B.*).—*Asclepias curassavica*. (*W. H. M.*).—1, *Cystopteris fragilis*; 2, *Asplenium fontanum*; 3, a luxuriant specimen of the *Ceterach officinarum*, var. *crenatum*. (*E. M., Sandy Mount*).—It is not the Pansy you name. The other plants were smashed by the post-office punches. (*H.*).—Your plant is *Epipactis latifolia*. Can you send us a living plant carefully dug up with a ball of the soil round it? If so, you will oblige. (*Alethea*).—Not a Lichen, but a *Hepatica*—*Marchantia polymorpha*. (*Mrs. Atkin*).—*Narthecium ossifragum*. Probably found wild near Dublin.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COOKING OLD FOWLS.

WE have told you which fowls to kill; we have told you how to kill them; we have endeavoured so to advise that you shall have them tender, yet sweet, in the hottest weather,

and we thought that was enough. It seems not. We have a very melancholy letter from "A RECENT SUBSCRIBER," who complains we deal only with her young poultry. She would like to know what she is to do with the old. We have told her hens do not lay in the winter. She has sent some to market twice, but either from the time of year or because they are in such bad plumage no one would buy them. Her letter ends with the question, "What am I to do with them? How can they be made eatable?"

It is only in England a hen is considered almost useless (except in regular kitchens). In any other country she is known to be the most valuable adjunct to that useful receptacle, the stock-pot. Go into the meanest peasant's kitchen in France. On the hearth, in the braise, there stands the "marmite," not boiling, but simmer, simmer, always. The coarse piece of beef, thanks to this long and gentle treatment, comes out the tender and relishing bouilli, and the good woman would be too happy to have the despised hen. She knows the flavour, strength, and brightness it gives to the "potage" of the aristocratic table, or the humble "soupe" of the farm or cottage.

That is not the only way of dressing your old hen or cock. When you have one, two, or three of these that must be made away with, start for a razzia in your larder and pantry. The lean of that ham, the odd pieces that remain on the bones of beef and mutton, corners of fat bacon, any scraps or pieces, nothing comes amiss: therefore, if you have none, buy some scrag or flap of mutton, coarse pieces of beef, three-cornered remnants of any food. Cut your fowl or fowls into joints. Cut also your meat into moderate-sized pieces. Season to your mind. Get an earthen pot, or terrine, with a lid to it, cut some thin slices of bread and cover the bottom and sides of the pan with them, then cut your bacon into as good slices as you can, and lay them on the bread. Then begin the artistic work. Take your pieces of meat and poultry and lay them as you will—make a mosaic. No skill is required, all that is necessary is to fill the vessel with meat. You are like Sydney Smith's cook and her puff paste, it cannot enter your head you are doing wrong. When the vessel is filled with meat, pour in water (gravity is better), until all the crevices are filled up with it. Put on the lid, tie it down, put it in a slack oven for eight or ten hours, and when it is cold eat it. You will like it, the water will be turned to jelly, and the odd pieces of meat will look as if they were set in transparent gold. This is a better winter than summer dish, but it is always excellent on the breakfast-table. It will do good service on the sideboard when unexpected company drops in. It is good for a fishing party, a pic-nic, or a shooting luncheon. In fact, the old hens will be found good food.

EXPERIMENT ON CHILLING EGGS.

I now give the result of the sitting of eggs named in a former communication to your Journal. Two chillings of eggs extra have occurred, which I think further proves that eggs are not very easily spoilt by a hen leaving her nest, at least in warm weather.

The course pursued was as follows:—Hen sat on nine Cochon eggs at ten o'clock at night Tuesday, 28th July. Time of hatching, 18th August.

July. No.
29, Wednesday.....1 taken away at 10 o'clock at night, replaced at 10 o'clock on following morning.
30, Thursday.....Hen on nest at 4 o'clock in the afternoon, at 10 o'clock on another nest.
31, Friday.....2 taken away at 10 o'clock at night, replaced at 10 o'clock on following morning.

Aug.		No.	10 o'clock		10 o'clock
1, Saturday.....	3	"	10 o'clock	"	10 "
3, Wednesday.....	4	"	10 "	"	10 "
7, Friday.....	5	"	10 "	"	10 "
10, Monday.....	6	"	10 "	"	10 "
12, Wednesday.....	7	"	10 "	"	10 "
14, Friday.....	8	"	10 "	"	10 "
16, Sunday.....	9	"	10 "	"	10 "

Wednesday morning, the 19th, Nos. 3, 4, 8 hatched.
Wednesday night, at 10 o'clock, Nos. 1, 2, 6, 9 hatched.
Thursday morning broke the two remaining eggs, Nos. 5 and 7. Both had full-grown chicks in them, dead.

After the hen had been sitting twenty-four hours I took No. 1 away, and it was chilled for twelve hours. I saw the

hen on the nest the following day at four o'clock; and at ten o'clock at night, intending to take egg No. 2 away as I had done the preceding, I found her on another nest, the eggs quite cold. I placed her on the nest again. On the following night I took egg No. 2 and returned it in the morning, and at the same hours as with No. 1. The hen sat well until Friday, the 14th, when at night I found her sitting so light on the eggs that all the outside ones were almost cold, the inner ones tolerably warm. On Saturday morning, the 15th, the hen sat on the edge of the nest and all the eggs were quite cold. I again placed her on the nest, and she afterwards sat close. Her time of hatching would be Tuesday, the 18th, on which night I found one egg chilled. More might have been so, but I did not wish to disturb her. On Wednesday morning I found three hatched, and at ten at night I found four more hatched. Being so late in the season and not caring for the chickens, being only an experiment, I broke Nos. 5 and 7, in which were full-grown chicks, dead. No doubt these had been from under the hen, one of these eggs (No. 5) having been chilled on the 7th of August and No. 7 on the 12th. Had that affected them they could not have been full-grown chickens. Than the seven chickens hatched I never saw stronger.

In addition to the above, I had an opportunity of trying whether an egg not impregnated would addle as my Bantam eggs before-named had done. A hen with chickens in a compartment of my aviary laid her first egg, no male bird being with her. This I placed under the sitting hen on Monday, the 10th. On the 20th I broke it, and found the white and yolk perfectly separate, as in a fresh-laid egg, the only difference being a slight cloud in the centre of the yolk. —EVESHAM.

DRIGHLINGTON AND ADWALTON POULTRY SHOW.

It is the ninth annual meeting of this Society that is just concluded, and it gives us pleasure to state that its excellence has been progressive. Although during the time of this Society's existence the Committee have frequently had serious drawbacks from the most unfavourable weather at their annual meetings, nothing daunted they have persevered, and certainly, though not a very extensive exhibition, this year's Show, in point of excellence, would bear very favourable contrast with many of our local poultry meetings.

There are, nevertheless, some of its rules that are quite open to improvement, none more so than the issue of catalogues prior to the awards of the Judges. At Drighlington catalogues were publicly sold about the streets many hours before the arbitrations commenced. This error is always fraught with objections, and as invariably offers a plausible opportunity for cavil to disappointed rivals, though no such instance met our ears in this particular case. The remedy will be very easily effected on future occasions by refusing to issue any catalogue whatever until the awards are completed.

In *Spanish* the only birds requiring particular remark were the two winning pens, adults first, chickens second. Both pens were exceedingly good and well shown. Strange to say only a single pen of *Grey Dorkings* were shown, but they were very good. In *Cochins* the result was even still more unexpected, not a single entry taking place, which perhaps is the only instance recorded at any of our public meetings in this now almost universal breed. The *Game* fowls of all varieties were well shown, and some of the *Brown Reds* were unexceptionable. In the *Hamburghs* we anticipated seeing a superior collection, nor were we disappointed. In these birds, however, Miss Emily Beldon quite ruled the roast, taking with a single exception all the *Hamburgh* prizes; indeed, all the fowls of whatever varieties shown by this exhibitor were so unusually good that she monopolised about twenty prizes besides commendations for her entries. The *Polands* were as good as we have seen for years past.

The class for *Aylesbury Ducks* was comparatively a failure, though the winning pens of *Rouen* were superior ones. The great feature of the Show was a competition for single cocks of any kind in one general class. A magnificent *Golden Poland* took first prize, a superior *Spanish* cock stood second, a *Silver Poland* realised third position, the

fourth fell to a *Brown Red Game* cock, the fifth prize was awarded also to a *Brown Red Game* cock, and the sixth to a *Golden-pencilled Hamburgh*. This class caused much interest among spectators, and was decidedly the most meritorious part of the Drighlington Show. The weather very unfortunately in the forepart of the Show day was most unpromising, but towards the afternoon the long-looked-for change took place, the rain ceased, and the day's proceedings concluded under a brightened sky.

SPANISH.—First and Second, Miss E. Beldon, Gilstead, near Bradford.
DORKINGS.—Prize, Miss E. Beldon, Gilstead, near Bradford.
GAME (Black-breasted or other Red).—First, Miss E. Beldon, Gilstead, near Bradford. Second, H. Snowdon, Horton, Bradford. Highly Commended, Miss E. Beldon; J. Mason, Drighlington.
GAME (Duck-winged or other Grey or Blue).—First, J. Fell & Sons, Adwalton. Second, H. Snowdon, Horton, Bradford.
GAME (Black or Brassy-winged).—First, G. Bartley, Gomersal. Second, G. Noble, Staincliffe, Batley.
GAME (White or Fife).—First, J. Mason. Second, H. C. Mason.
HAMBURGH (Golden-spangled).—First and Second, Miss E. Beldon, Gilstead, near Bradford.
HAMBURGH (Silver-spangled).—First and Second, Miss E. Beldon, Gilstead, near Bradford.
HAMBURGH (Golden-pencilled).—First, Miss E. Beldon, Gilstead, near Bradford. Second, F. Hardy, Quarry Gap, Bradford.
HAMBURGH (Silver-pencilled).—First and Second, Miss E. Beldon, Gilstead, near Bradford. Highly Commended, J. Walker, Drighlington.
POLANDS.—First, Miss E. Beldon, Gilstead, near Bradford. Second, D. Hingworth, Batley, Otley. Highly Commended, Miss E. Beldon. Commended, F. Hardy, Bradford.
ANY DISTINCT BREED NOT MENTIONED.—First and Second, Miss E. Beldon, Gilstead, near Bradford.
GAME BANTAM.—First, G. Noble, Staincliffe, Batley. Second, Miss E. Beldon, Gilstead, near Bradford. Highly Commended, Miss Bland, Drighlington.
BANTAMS (Any other variety).—First, S. Schofield, Heckmondwike. Second, Miss E. Beldon. Highly Commended, R. Ferrett, Drighlington.
GEESSE (English).—First, G. Yates, Westgate-Hill, Tong. Second, J. Hagge, Crow Nest, Dewsbury.
GEESSE (Any other distinct breed).—Prize, G. Yates, Westgate-Hill, Tong.
DUCKS (Aylesbury).—First, H. Helliwell, Adwalton. Second, C. Holmes, Tong.
DUCKS (Rouen).—First, J. Rhodes, Tong. Second, J. Ward, Drighlington.
COCK (Any breed).—First, Second, and Sixth, Miss E. Beldon, Gilstead, near Bradford. Third, F. Hardy, Bradford. Fourth, H. Snowdon, Horton, Bradford. Fifth, H. C. Mason, Drighlington. Highly Commended, H. Snowdon; W. Bentley, Scholes, Cleckheaton; J. Fell & Sons, Adwalton. Commended, R. Farrhill, Carlough, Batley.

The Judge was Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham.

ORMSKIRK AND SOUTHPORT POULTRY SHOW.

The seventh annual Exhibition of the Society was held at Ormskirk on Wednesday last the 19th inst., and was well attended considering the capricious state of the weather.

The poultry entries were more numerous, 108 pens being exhibited, and the quality better than at any previous meeting of the Society; in confirmation of which, among the exhibitors figure the names of Captain Hornby, Mr. Teebay, Mr. Stretch, Mr. Musgrove, Mr. Dixon, and other well-known exhibitors. Owing to the time of the year the old birds showed indifferently, especially in the *Cochin* classes. The following is a list of the prizes awarded:—

DORKINGS.—First, Capt. Hornby. Second, J. Blundell, Burscough.
CHICKENS.—Second, J. Holme, Knowsley. Highly Commended, P. Riley, Searnlock. First withheld.
SPANISH.—First and Second, R. Teebay, Fulwood. **CHICKENS**.—First, Capt. Hornby. Second withheld.
GAME (Black or Brown-breasted Red).—Second, W. Howard, Knowsley. First withheld. **CHICKENS**.—First, Capt. Hornby. Second, J. B. Rutter, Toulton-le-Fyde. Highly Commended, J. Eaves, Knowsley. Commended, Capt. Hornby.
GAME (Any other colour).—**CHICKENS**.—First, J. Holme, Knowsley. Second, J. Eaves, Knowsley. Highly Commended, J. Eaves.
HAMBURGH (Golden-pencilled).—First, J. Dixon, Bradford. Second, T. Ridgway, Burscough.
HAMBURGH (Silver-pencilled).—First, J. Dixon. Second, J. W. Smith, Rivington.
HAMBURGH (Golden-spangled).—First, J. Dixon, Second, T. Ridgway.
HAMBURGH (Silver-spangled).—First, R. Teebay, Fulwood. Second, J. Dixon, Bradford.
COCHIN-CHINA (Buff).—First, E. Musgrove, Aughton. Second, T. Stretch, Ormskirk. Commended, T. Stretch. **CHICKENS**.—First and Second, T. Stretch. Commended, E. Musgrove.
COCHIN-CHINA (Partridge or Grouse).—First and Second, T. Stretch, Ormskirk. **CHICKENS**.—First and Second, T. Stretch. Highly Commended, J. B. Walthew, Aughton.
POLAND (Any colour).—First and Second, J. Dixon, Bradford.
GAME BANTAMS (Black or Brown-breasted Reds).—Prize, E. Musgrove, Aughton.
GAME BANTAMS (Any other colour).—Second, J. B. Walthew, Aughton. First withheld.

BANTAMS (Any other variety).—First, J. Dixon, Bradford. Second, withheld.
GAME COCK (Any colour).—First, W. Boyes, Beverley. Second, J. S. Rutter, Poulton-le-Fylde. Highly Commended, J. Eaves, Knowsley.
GEESSE.—First, J. Bryers, Ormskirk. Second, Capt. Hornby. Commended, R. Wright, Warrington.
DUCKS (Aylesbury).—First, J. Dixon. Second, T. Stretch, Ormskirk. Highly Commended, T. Stretch.
DUCKS (Rouen).—First, J. Dixon, Bradford. Second, Capt. Hornby. Highly Commended, T. Stretch, Ormskirk.
DUCKS (Any other variety).—First, J. Dixon. Second, F. W. Earle, Turkeys.—First, Capt. Hornby. Second, J. Dixon.

ALDBOROUGH AND BOROUGHBIDGE POULTRY SHOW.

THIS Poultry Show was held on the 11th instant. Some of the poultry was remarkably good. In *Spanish* Miss Beldon showed an excellent pen. *Dorkings* were very good, especially the chickens, which class was highly commended, the first-prize chickens being remarkably good. *Game* was only average. *Cochins* were good, but the chicken class was better than the adults, and the first-prize chickens were a very fine pen. All the *Hamborough* classes were above an average. The first-prize pen of *Polands* were good.

The *Geese* were not good; but the *Aylesbury Ducks* made amends, Mr. Kell taking the first prize both for adults and ducklings with birds that are hard to beat anywhere. The *Pigeons* were very good.

DORKINGS.—First, Rev. G. K. Holdsworth, Aldborough. Second, Miss Beldon, Gilstead, Bingley. *Chickens*.—First, — Kell, Wetherby. Second, Rev. G. K. Holdsworth. (Class Highly Commended).
SPANISH.—First and Second, Miss Beldon, Gilstead, Bingley. *Chickens*.—First, Miss Beldon. Second, F. Powell, Knaresborough.
GAME.—First, Miss Beldon, Gilstead. Second, J. Robshaw, Whitley. *Chickens*.—First, J. Robshaw. Second, Miss Beldon.
COCHINS-CHINA.—First, R. Gateby, jun., Shipton (Buff). Second, T. H. Barker (Buff). *Chickens*.—First and Second, — Dewes, Knaresborough (Buff). Commended, T. H. Barker, Hovingham (Buff); — Dewes.
HAMBROUGHS (Golden-spangled).—First, J. Waddington, Minskip. Second, Miss Beldon, Gilstead. *Chickens*.—First, J. Apew, Cowthorpe. Second, Miss Beldon.

HAMBROUGHS (Golden-pencilled).—First, Miss Beldon, Gilstead. Second, — Ellerby, Helmsley. Commended, H. S. Harcastle, Hunsingore. *Chickens*.—First, Miss Beldon. Second, J. Darbyshire, Whitley.
HAMBROUGHS (Silver-spangled).—First, Miss Beldon, Gilstead. Second, — Blenkhorn, Knaresborough. *Chickens*.—First, Miss Beldon. Second, Mrs. Gray, Boroughbridge.
HAMBROUGHS (Silver-pencilled).—First, Miss Beldon, Gilstead. Second, — Harcastle, Hunsingore. Highly Commended, — Scollick, Bickerton. *Chickens*.—First, Miss Beldon. Second, — Kendall.

POLANDS.—First, Miss Beldon, Gilstead. Second, C. Marwood, Aldborough. *Chickens*.—First, Miss Beldon.

BRABMA POOTRA.—First and Second, F. Powell, Knaresborough. *Chickens*.—First, Rev. G. K. Holdsworth, Aldborough. Second, F. Powell, Knaresborough.

BANTAMS (Game).—First, Miss Beldon, Gilstead. Second, — Lamb, Great Ouseburn. *Chickens*.—Prize, J. Spencer.

BANTAMS (Gold or Silver).—Prize, Miss Beldon, Gilstead.

BANTAMS (Any other variety).—First, Miss Beldon, Gilstead. Second, J. Chapman, Great Ouseburn. *Chickens*.—Prize, Mrs. Stapilton, Myton Hall.

ANY OTHER DISTINCT BREED NOT MENTIONED.—First, Miss Beldon, Gilstead. Second, — Ingleby, Knaresborough (Golden Pheasants).

FARMYARD CROSS.—First, Mrs. Burton, Minskip. Second, J. Spencer, Aldborough. *Chickens*.—Prize, — Sudds, Aldborough.

TURKEYS.—First, Mrs. Burton, Minskip Grange. Second, — Moorey, Mulwith. *Poult.*—First, — Moorey, Mulwith. Second, Captain Barnes, Thorp-Green Hall.

GEESSE.—First, C. F. G. Clark, Heaton House. Second, — Moorey, Mulwith. *Goostings*.—First, A. Low. Second, — Clark, Heaton House.

DUCKS (Aylesbury).—First, — Kell, Wetherby. Second, — Young, Driffield. *Ducklings*.—First, — Kell, Wetherby. Second, — Clark, Heaton House.

DUCKS (Rouen).—First, — Barker, Hovingham. Second, — Young, Driffield. *Ducklings*.—First, Miss Graham, Aldborough. Second, — Sudds, Aldborough.

DUCKS (Any other variety).—First, Rev. J. G. Milner, Bellerby. Second, Mrs. Hewison, Norton-le-Clay (Indian).

GUINEA FOWLS.—Prize, — Webster, Moor Monkton.

PIGEONS.—*Croppers*.—Prize, — Trenam, Helmsley. *Carriers*.—Prize, G. Sadler, Boroughbridge. *Trumpeters*.—Prize, Miss Beldon, Gilstead. *Jacobins*.—Prize, Mrs. Sedgwick, Aldborough. *Fantails*.—Prize, Miss Beldon. *Tumbler*.—Prize, Miss Beldon. *Dragons*.—Prize, G. Sadler. *Barbs*.—Prize, Miss Beldon. *Nuns*.—Prize, Miss Beldon. *Any other variety*.—Prize, Miss Beldon.

RABBITS (Fancy).—Prize, I. Slade, Boroughbridge.

EXTRA STOCK.—Prize, Mrs. Hewison, Norton-le-Clay (Indian Ducklings).

The Judges were Mr. Hunter, Green Hamerton, and Mr. Scott, Boroughbridge.

TWO QUEENS IN ONE HIVE.

MR. LOWE talks of my fluent pen being ever ready to answer all inquiries and to solve all the doubts of the numerous parties who appeal to me for advice and inform-

ation: what will he now say when *Œdipus* himself confesses to being fairly posed? Will he come forward in his turn and with fluent pen solve the mystery at once? Or will any other among the numerous accomplished aparian contributors to *THE JOURNAL OF HORTICULTURE* expound the riddle which I am about to submit to their consideration? Time will show, but I will at once state what has surprised me, and then as the journalists say, "pause for a reply."

The incident which has so much astonished and puzzled me is, this day (August 19th), finding two queens peaceably installed in one hive. The first was evidently the mother of the colony moving slowly over one comb with all the state and dignity proper to her matronly condition, and the second was standing on another comb (separated by two others from the one on which the mother of the hive was parading), and receiving apparently equal respect with the rightful sovereign from a circle of courtiers that surrounded and attentively regarded her.

The colony itself is a pure *Ligurian* which has been treated for, and apparently cured of, foul brood in the manner detailed in page 97—that is, the bees were driven into an empty hive in which they were kept four days, and then again driven into another hive with a few clean combs, in which they were suffered to remain unmolested. This process was completed about a month ago, and now the hive is half filled with combs in which is some honey and a great deal of brood in all stages. In fact, the colony is precisely in the condition of a recent swarm of moderate size, which has half filled its hive and has a fertile queen at its head.

The old queen is large and evidently very prolific, whilst her junior is also of full size; but judging from her contracted abdomen is probably still a virgin.

Now, what under these circumstances can have caused the bees to raise a second queen? and what can have induced the queen regnant to brook so near a rival to the throne? As I said before, "I pause for a reply."

I should state that I removed the supernumerary queen as soon as I discovered her, and placed her at the head of a queenless colony. It is, of course, very doubtful whether she will remain there, as, if she has already taken wing, she will probably soon find her way back to her old quarters. The event will, however, be watched with some interest by —A DEVONSHIRE BEE-KEEPER.

FOUL BROOD NOT AN ARTIFICIAL DISEASE.

LET me assure Mr. Lowe that he is entirely mistaken in considering foul brood to be identical with chilled brood. There is really quite as much difference between them as there is between smallpox and a common cold in the human subject; and chilled brood, when free from infected matter, appears as little likely to degenerate into foul brood, as a cold in the head to produce confluent smallpox in the absence of contagion. The simile of the unhatched eggs of a domestic fowl is also by no means correctly put. If thoroughly chilled all may die, and so may that portion of the brood of a hive which is uncovered and neglected by the bees. But here the mischief ends: the next sitting of eggs hatches out all right; and so also with bees—chilled brood is removed, and the cells again tenanted on the return of warm weather, or an increase in the population. I know little of the management of poultry, but I think I may safely assume, that if the eggs of at first a few hens, and ultimately those of every hen in the poultry-yard, were found perfectly incapable of hatching, although the mothers sat fairly, and every care was taken of them, the poultry-keeper would be right in attributing the circumstance to disease, and would be sadly mistaken if he persisted in ascribing his misfortune to the momentary absence of the hens, which had constantly occurred in former years, but had never before been attended with such disastrous effects.

Mr. Lowe says, "If foul brood be a disease, I should like to know by what it is caused." So should I. And a great many other people would like also to know the causes of the potato disease, pleuro-pneumonia in cattle, variola in sheep, strangles in horses, and distemper in dogs, but I never heard any one doubt the reality of these diseases because their occult causes remain obscure.

It is true that mine is, to a very great extent, an experimental apiary, and that when once the poison had been introduced by means of infected combs from common hives, I, in my ignorance, assisted its dissemination through all my colonies by the very endeavours which I made to palliate it; but Mr. Lowe is quite mistaken in stating that "it is only in the hands of the experimentalist that we find it generally manifested." I will give a case in point. Mr. Quinby, an American writer, and the cleverest and most sensible apiarian of the old school that I have ever met with, has lost as many as a hundred stocks in a single year from this pestilence, although he kept bees in the ordinary manner in simple boxes without bars or frames; whilst Mr. Langstroth, who claims to be the original inventor of frame-hives, and is probably by far the most scientific and experimental apiarian in America, declares that it has never made its appearance in his apiaries, and that he should regard its general dissemination in America as the greatest possible calamity to bee-keeping.

I can also state that the process of driving healthy bees one day, stowing the deserted hive in a warm kitchen during the night, and fitting the combs into frames the next morning,* is by no means deserving of the reprobation with which Mr. Lowe has visited it. Of course, when the hive is on the spot none of these delays should take place; but the actual mischief is very trifling, being confined to the loss of a few of the larger worms which protrude from their cells, and are speedily removed by the bees. Neither the eggs, very young brood, nor that which is sealed over, is at all injured, nor can foul brood be created in this manner, as I have proved repeatedly in former years. The fact is, if foul brood were identical with chilled brood, I should have met with it long ago, nor would my friends, Mr. Fox, "B. & W.," "J. E. B.," Mr. John P. Edwards, and hundreds of others, have entirely escaped it.

I do not expect to convince Mr. Lowe, nor am I by any means sure that a bystander would not deem me out-argued, since the firmness of Mr. Lowe's convictions is fully equalled by his ability in maintaining them; but in this case I have had ample opportunities of judging, and I may confidently ask the apiarian readers of THE JOURNAL OF HORTICULTURE, if I have ever misled them in a single instance which has fairly come under my observation as—A DEVONSHIRE BEE-KEEPER.

P.S.—Since writing the foregoing I have perused Mr. Edwards' excellent article in page 137, for which, as well as that in page 120, I beg to tender him my best thanks. He has, I perceive, anticipated some of my arguments in another form, and confirms much of my own experience in driving, artificial swarming, the effects of chloroform, &c.

THE FOUL BROOD CONTROVERSY.

APIARIANS have the character of being the most prejudiced class in the world; and surely we have had an instance of this characteristic lately, when we find Mr. Taylor, Mr. Lowe, and Col. Newman—men who have carefully studied the habits of bees—attacking "the experimental" apiary of Mr. Woodbury, and almost rejoicing over what they would call the failure of his "scientific" management; and by exaggerating or misinterpreting it, they seem to want to drive us back to nature, as they call the old-fashioned straw skeps and swarming system. I am afraid that we, who are anxious to learn from the experience and misfortunes so generally divulged by "A DEVONSHIRE BEE-KEEPER," cannot hope to benefit by a discussion of the question whether foul brood is a disease or not.

Mr. Lowe, who acknowledges that he passes over cursorily the experience of other writers on the diseases of bees, has found this disease, or complaint, or malady, or evil, or whatever he may choose to call it, in his own hives. But is he not taking for granted the cause of it—namely, a sudden chill to all the brood affected? It is quite as probable that this evil has a small beginning, and spreads rapidly throughout the hives, since experience teaches that a hive attacked by it rarely recovers, but that all the comb becomes affected.

Mr. Woodbury, by the great advantage his "experimental" system gives him over Mr. Lowe, has discovered that it is

contagious, and probably infectious too. Mr. Lowe compares the evil to the chilling of eggs which are being hatched. Has he found that one chilled egg will communicate its rottenness to other sound eggs? The origin of the disease foul brood is still a mystery to us English bee-keepers, like that of typhus, or cholera, or the potato disease (does Mr. Lowe deny the name of "disease" to the last?) and our object should be to collect as much information on the subject as possible, and not to check the efforts of our pioneers by a sneer at their failures.

Mr. Woodbury has communicated promptly his bad success that all might learn from him. The cause of it he was enabled to discover, because his system was a scientific one. How many old-fashioned apiaries have died out during the last three or four years, and the cause of their death left in obscurity because their owners would not be "fighting against nature?" And yet this fatal visitation is denied to be a disease, or, at least, called "an entirely artificial one," in face of the acknowledged ignorance which prevails in England on the subject, and in face, too, of the larger experience of bee-keepers in Germany and America. Our immunity must surely be the immunity of ignorance only.

Our progress in knowledge on this interesting branch of natural history will be lamentably slow if our writers on the subject persist in "passing over with a cursory glance" the information afforded by others, even though they be foreign bee-keepers, and perhaps ignoring them altogether.

One word more on those that oppose the scientific and experimental system. Are we to fall back on the cottager's usual reason for the dwindling of a hive—"There is something the matter with the queen," when Mr. Woodbury has been able, by scientific management, to discover and cope with a disease in his apiary, which may have been the unknown cause of the destruction of many apiaries on the old system? Mr. Edwards has referred to the artificial treatment of the cow and sheep as authority for the "rational management" of bees. I, too, would ask these "followers of nature" why we may not increase the breeding of our bees much in the same way as we increase the laying of our hens?

Mr. Woodbury's establishment is for the purpose of propagating the Ligurian breed, not for making honey: at least so I understand. His success is proved by the numbers of Ligurian colonies which he has spread over England.

I have heard of diseases running through the stock of horse-breeders; but I have not heard that their misfortune was attributed to their assisting nature by keeping their stock in stables and boxes, and on good food, instead of letting them run wild.

I must apologise for the length of my letter, but it is on a subject on which I, in common with so many other bee-keepers, feel strongly. We cannot hope for improvement in bee-keeping in England, if the efforts toward progress are so unceremoniously snubbed. And there is no English bee-keeper who ought not to feel, and be ready to express, his gratitude for the information which Mr. Woodbury has so freely placed within his reach?—W. C. ELLIS, *Bethal*.

I HAPPEN to possess a copy of a book translated some years ago from the original of Jonas de Gelieu, entitled the "Bee Preserver," and which the author tells us is "the result of sixty-four years experience." From this high authority we have the following passage—"Bees have no real disease. Dysentery, about which so much noise has been made, never attacks the bees of a well-stocked hive that is left open at all seasons, but only those that are too long and too closely confined. All their pretended diseases are the result of hunger, cold, or the infection produced by a too close and long confinement during the winter." Nothing is here said about a so-called malady—"foul brood." Foul, indeed, is the state of things, when in early spring the stock has been so much weakened, no matter how, that the labourers are insufficient to bring out the grubs that have perished prematurely for want of the warmth necessary to mature them, only to be insured by adequate numbers. Is more required than thousands of rotting carcasses (sensitive as bees are to the least offence), to fill the hive with unnatural stench and ultimate disease? What would be the condition of a human family under analogous circumstances—viz., supposing a dead body in a house were to remain unburied

* All this is, of course, only permissible during warm summer weather.

and uncoffined week after week, till every room was charged with infectious effluvia? I suppose, like the bees, the inmates would be glad to beat a retreat. This appears to me a common-sense view of the matter, without racking the brain to find out more causes than are needed to produce the effect.—A SUBSCRIBER.

AFTER reading the very able articles by the "DEVONSHIRE BEE-KEEPER," and Mr. Lowe, on the important question of foul brood, which is so detrimental to all bee-keepers, I think that by putting the two letters together every one will come to the conclusion that foul brood is caused both by experimenting with the bees, and the late bad seasons. There is no doubt that if the comb with grub in it is left for one night without the bees it will perish, and the bees will not be able to hatch it out, just the same, as with eggs, only some of which will hatch if left to cool. Thus if only part of the grub is hatched, and the other left in, being incapable of being hatched-out, it will become foul, and so prevent the hive from flourishing. In the bad seasons we have had, innumerable hives have been lost both in the spring and winter from starvation, and the young larvæ being left in the cells unhatched become foul, and then fresh bees are put in the same hive where the foul brood is, with the idea that the bees, having a house ready furnished, will go on and prosper well; but it is the reverse, the bees being unable to clear the hive of the foul brood, and the queen having no place to deposit the eggs in, the consequence is, the bees dwindle away, and so the infection spreads through the apiary.—L. C.

I WAS glad to see the articles on bees in No. 125, and am sure all apiarists are much indebted to the "DEVONSHIRE BEE-KEEPER" for his numerous letters on these interesting insects, and bringing this foul-brood discussion forward. We shall now understand the cause of bees dwindling away, and, consequently, the remedy. From what "A LANARKSHIRE BEE-KEEPER" and Mr. Lowe say, any of your readers will know what foul brood is and its cause, and may, therefore, find a remedy.

I had a common straw hive which died out in the winter of 1861, and last autumn I put the bees out of a large hive into it, and at the same time mixed and transferred several others; but this spring and summer I observed that the bees seemed to decrease, and, therefore, supposed there was no queen, or, if there was, that she was not a prolific one. On the 9th of July I fumigated it and found very few bees, and also a queen. I destroyed her and joined a third swarm to the hive, but the bees would not let the queen stay in the hive, and she and a few of her own bees came off as a swarm and were hived. The next day they came off again and flew away and were lost.

The hive seemed to work better than before, and I thought this queen might have gone back; but seeing lately the bees growing less and less, I made sure there was no queen, and, therefore, thought it best to fumigate and join them to one of my Ligurians; but after looking nearly all the bees over discovered they had made a queen, and instead of returning her and the bees to the same hive, I took a hybrid queen from the observatory-hive and joined her and the bees to it. On examining the comb I found some of the cells full of a kind of white matter, a few worms, and some grub that appeared to have been long sealed over. I had, therefore, little doubt that this hive was affected with foul brood, and I burnt all the combs. There can be no doubt a hive full of comb after dying-out is not fit to put bees in again.—A. W.

RANDOM APIARIAN NOTES.

1. THE temptation is irresistible to ask "AN OLD-FASHIONED BEE-MASTER" to furnish us with statistics of his "inexpensive row of straw hives," which give him "neither trouble in management nor anxiety about the harvest in due season." Let him say how much *bonâ fide* honey he has obtained from his apiary during each of the last five years, particularising the number of hives plundered and how plundered, the amount of pure honeycomb or raw honey yielded by each hive. He would oblige by also stating the experience of cottagers and others in his neighbourhood during the same period.

Mr. Woodbury's apiary is not merely scientifically con-

ducted: it must be borne in mind that it is in great measure an experimental one. His object has not been to obtain honey, but to multiply and disperse abroad a new species of bee till recently unknown in England. If Mr. Woodbury would enter into details, I think he would astonish some old-fashioned bee-masters by his statement of the eminent success which has attended his labours. The misfortune under which he is now—let us hope only temporarily—suffering, is no more than such as may attend any old or new-fashioned system of management; with this difference, however—that whereas an old-fashioned apiary would probably have died out under such a visitation, our scientific friend, we may safely predict, will not fail to triumph over the enemy in the end.

As a scientific apiarian myself, I may say without egotism, I have been most successful, as witness my experience recorded in these pages during the last twelve years. Even in ordinarily bad seasons I seldom fail to get my fair quatum of honey; and I will challenge any apiarian situated like myself to a comparison of notes without much fear of the result, be he "AN OLD-FASHIONED BEE-MASTER," or one of the "scientific" race.

In this part of England I know of many old-fashioned apiaries that have utterly perished during the last three years, while I have heard of little or no honey being obtained from any of them. The only successful apiaries about here are precisely those, and those only, which are scientifically managed.

2. I must beg entirely to differ from Col. Newman in his estimate of the effects of artificial swarming upon the spirits of bees and their activity. My own experience goes to prove that a judicious use of the power we have to compel bees to swarm is most beneficial, and that many a sluggish hive would be, and has been, quickened to "unusual activity" by a resort to this expedient. The fact is that you cannot, do what you will, diminish the activity of bees, provided they have a fertile queen, a considerable population, fair weather, and a suitable dwelling—it is altogether "against nature." An hour after the greatest disturbance they will be as busily occupied as if nothing had happened.

3. Again, Col. Newman hits hard at the indispensable practice of "driving" bees. But I need not comment upon his remarks, as Mr. J. P. Edwards has fully entered into the subject, and well explained the *modus operandi*. Occasionally a failure will occur, but in nineteen out of twenty cases success always rewards the persevering and scientific bee-master. Driving is now an established *sine quâ non* in every scientifically conducted apiary, and has been so for a century and more. Of course it is sometimes a tedious operation, and it is rather warm work on a hot day; but it is certainly one of the prettiest and most interesting among the labours of the bee-keeper, and is often very simply and quickly done.—B. & W.

DESTROYING DRONES.

I HARDLY feel myself qualified to take part in the great debate which your pages maintain with so much spirit on the economy of bees; but I should like to be informed what reason can be rendered for the unqualified opinion given in page 100, to the effect that drones should on no account be killed.

I recollect that in Taylor's bee book, to which many of us look up as to a great authority, a remarkable instance of artificial drone-killing is recorded, and the practice is recommended to the bee-keeper's consideration.—J. EARLE.

[No one shall bow more willingly to an opinion of that Nestor of the apiary, Mr. Taylor, than ourselves; yet "a man's a man for a' that," and we follow the example of no less an authority than Galileo, who when compelled to recant, said aside, "But the earth goes round the sun for all that." However, we wished to hear what another authority would say, and sent your note to "A DEVONSHIRE BEE-KEEPER," who replies—"My idea is, that killing drones oneself is usually too troublesome, but if it can be readily done as soon as their office is accomplished, it would be decidedly advantageous to get rid of the whole of them." That is our opinion also, but we are also of opinion that the bees know when "Othello's occupation's gone," better than the bee-keeper.]

EXPERIMENTING ON BEES.

WE who commiserate the condition of the "DEVONSHIRE BEE-KEEPER," with reference to the losses in his apiary, ought to be careful not to imitate the comforters of Job, who attributed all the miseries and misfortunes of the Patriarch to his own fault.

Those who try experiments with bees will often, doubtless, experience lamentable failures; but it is scarcely fair to attribute the complete and sudden break-down of our master in bee-craft to general mismanagement on his part.

I know that I have heretofore whilst experimentalising had many losses of valuable stocks, but I have at the same time, or during the same period, lost many a hive for whose decease I could attribute no satisfactory cause.

One good will arise to bee-masters from this loss to our respected friend, in that their eyes will now be opened to a fact to which many of them were formerly blind. I alluded in my last (page 109) to a hive which I thought would do no more good, and which I doomed to the "fuming-pot." This hive I have since taken, and I found "foul brood" therein and no mistake. Had I not read the account of such a disease in the letter of the "DEVONSHIRE BEE-KEEPER," I should certainly have given some of the honey, and, perhaps, comb, to others of my hives, and my loss next year might have been as great as his; as it is, I thank him for the opening of my eyes, and wherever I suspect the disease to lurk for the future, there fire and brimstone shall do their purifying work at once. I had observed throughout the summer that the hive in question gave forth a most unsavoury odour, and for the future this will be a hint not to be disregarded, and the suspected hive shall always be removed out of the way of infecting others.

With reference to the fuming of bees with fungus, may I add that I have tried it for years at all seasons of the year, strong doses and slight, and that I never could perceive that it injured those operated upon? A few at times have been killed, particularly when two or more swarms have been joined, or when large portions of the comb containing brood and honey have been removed from the stock; but this loss I have of late attributed, not to the effects of the fumigation, but to weapons of certain of the bees themselves, which certainly kill off their brothers whenever they wish for their removal, or think there is no more work for them to do. If I take off a super or middle-box, I do not now, as formerly, return the inmates, for if I do I invariably find slaughter to succeed. If, however, I "cruelly" slay them myself, I cannot discover that the remaining bees give any symptoms of a knowledge of the loss of the good of which they have been deprived.

I should be obliged by the Devonshire or Lanarkshire Bee-keeper giving me a reason for the supposed longevity of a queen bee. I am led to suppose that she does not see two winters, or, if she does, that the hive in which she is regnant will not be prosperous, and will shortly be destitute of subjects.—THE HAMPSHIRE BEE-KEEPER.

AN APPEAL ON BEHALF OF THE INFERIOR ANIMALS.

WE have received the following from an esteemed correspondent, and have great pleasure in giving it every publicity:—"It is a common observation that cases of brutality to horses, asses, and other large quadrupeds, are much less frequently witnessed now than they were some time ago. This is no doubt owing to the general increase of humanity, and to these animals being now under the protection of the law.

"An English gentleman would not himself give a moment's unnecessary pain to any living creature, and would instinctively exert himself to put an end to any suffering before his eyes; yet it is a fact that every game-preserver in this country sanctions a system which consigns thousands of animals to acute agony, probably of eight or ten hours duration, before it is ended by death. I allude to the setting of steel traps for catching vermin.

"The iron teeth shut together with so strong a spring that a pencil which I inserted was cracked and deeply indented by the violence of the blow. The grip must be close enough

not to allow of the escape of a small animal, such as a stoat or a magpie; and therefore when a cat or a rabbit is caught, the limb is cut to the bone and crushed. A humane gamekeeper said to me, "I know what they must feel, as I have had my finger caught." The smaller animals are often so fortunate as to be killed at once. If we attempt to realise the sufferings of a cat or other animal when caught, we must fancy what it would be to have a limb crushed during a whole long night between the iron teeth of a trap, and with the agony increased by constant attempts to escape. Few men could endure to watch for five minutes an animal struggling in a trap with a crushed and torn limb, yet on all the well-preserved estates throughout the kingdom, animals thus linger every night; and where gamekeepers are not humane, or have grown callous to the suffering constantly passing under their eyes, they have been known by an eye-witness to leave the traps unvisited for twenty-four or even thirty-six hours. Such neglect as this is, no doubt, rare; but traps are often forgotten, and there are few gamekeepers who will leave their beds on a cold winter's morning one hour earlier to put an end to the pain of an animal which is safely in their power.

"I subjoin the account of the appearance of a rabbit caught in a trap given by a gentleman who, last summer, witnessed the painful sight many times:—"I know of no sight more sorrowful than that of these unoffending animals as they are seen in the torture-grip of these traps. They sit drawn up into a little heap as if collecting all their force of endurance to support the agony; some sit in a half-torpid state induced by intense suffering. Most young ones are found dead after some hours of it, but others as you approach start up, struggle violently to escape, and shriek pitifully from terror and the pangs occasioned by their struggles." We naturally feel more compassion for a timid and harmless animal, such as a rabbit, than for vermin, but the actual agony must be the same in all cases. It is scarcely possible to exaggerate the suffering thus endured from fear, from acute pain, maddened by thirst, and by vain attempts to escape.

"Bull-baiting and cock-fighting have rightly been put down by law. I hope it may never be said that the members of the British Parliament will not make laws to protect animals if such laws should in any way interfere with their own sports.

"Some who reflect upon this subject for the first time will wonder how such cruelty can have been permitted to continue in these days of civilisation; and no doubt, if men of education saw with their own eyes what takes place under their sanction, the system would have been put an end to long ago.

"We shall be told that setting steel traps is the only way to preserve game; but we cannot believe that Englishmen, when their attention is once drawn to the case, will let even this motive weigh against so fearful an amount of cruelty."

OUR LETTER BOX.

POULTRY BOOK (T. D. S.).—Perhaps "Dixon's Ornamental and Domestic Poultry," will answer your requirements.

LOSS OF PLUMAGE (H. C.).—Shabby plumage and comparative nakedness are natural to fowls at this time of year. The feathers are worn out. The smart winter clothing of last October and November has become seedy. Nature being busy preparing the new suit has nothing to spare for the old. It is become shabby and brittle. As they are in a confined space, separate the cock from the hens. Feed well, but on cooling food, and if you will have patience you will find the plumage of your birds renewed to your satisfaction.

COCHIN-CHINA CHICKENS (A Young Beginner).—What sort of place do your chickens roost in? If it is at all damp that will account for their being weak on their legs. The mere fact of chickens having to get up four steps into the garden in which they are allowed to run could never affect them in this way. The Devizes Poultry Show was held on the 10th and 11th of February last. We do not know if the time is settled when the next is to take place. The Secretaries are Mr. Long and Mr. Mullings.

PRESERVING EGGS (A Constant Subscriber).—We have known eggs keep good from May to Christmas by dipping them in melted fat and storing them in a dry cold place.

RABBITS (Idem).—Your Rabbits have what is called ear-gum, and it is caused by being kept in a damp and close place where there is not a free circulation of air. As soon as you discover it procure from a chemist a little lead oil ment, with which dress the inside of the ear as low down as you can reach with a feather. Examine them every day and clean off with a piece of blunt stick all scab and secretion as it becomes loosened, and by careful attention you will soon overcome the disease.

UNICOMB-HIVES (An Isle of Axholme Bee-keeper).—The distance between the two gas surfaces in my uncomb-bive is an inch and two-thirds, as recommended by Dr. Bevan.—A DEVONSHIRE BEE-KEEPER.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 70.2°, and its night temperature 47.2°. The greatest heat was 85°, on the 1st, 1845; and the lowest cold, 28°, on the 7th, 1855. The greatest fall of rain was 1.50 inch.

CAN THE PERIOD OF FULL BLOOM BE LENGTHENED IN OUR FLOWER GARDENS?

THE transitory nature of the display produced by the present style of flower-gardening is not unfrequently one of the most powerful arguments which are urged against it.

It is not proposed in the remarks that shall here be offered to refute the charge: on the contrary, it is frankly admitted that the stirring appeal to our sense of that which is beautiful, as presented by the pleasing combinations of the gay host of flowers which form so conspicuous a part of our flower gardens, is even much shorter than is to be desired. A frosty morning or a ruthless blast towards the end of September disturbs our equanimity to no small extent; and the chances of such occurrences are

often discussed with a foreboding bordering on the melancholy. And who is there that cannot sympathise with the spirit that heaves a sigh of regret at the prospect of so much grace and beauty becoming a decaying putrifying mass in less than twenty-four hours? We did by chance meet a few days ago with a heart so benumbed to the influence of flowers, that it was frankly avowed that flowers of any kind or to any extent had no charm for him. We earnestly pitied so singular a subject.

More particularly is the shortness of the effect produced to be regretted on account of the months of forethought and hard labour which its production calls into play and necessitates. One could almost wish that a writer in "Once A Week," who has imbibed very sentimental ideas about the ease, and interminable and undisturbed pleasures and abundant remuneration, that are attached to a head gardener's situation, could be placed in the shoes of many a gardener who has one of our large flower gardens to manage now-a-days. Leaving all other departments out of the question, he would find out before very long that in this one department alone there is enough to make a head gardener's office not one of "unalloyed pleasure," and that there is something more both behind the scenes and on the boards too than "going about giving orders," and that, worst of all, it is not remunerated with splendid sums ranging from £200 to £1000 a-year with other et-ceteras. He would also, perhaps, make the important discovery that to spend so much of his time in artificially heated and confined air, and to pace a soil gorged with decaying vegetable matter, and surrounded with high walls and woods, was not the "most healthy" position in the world either. When a man writes about a thing that he does not know about, such, generally, are his lucubrations.

It is, however, admitted on all hands, that such a display as is now produced in our flower gardens has never been equalled by any system of arrangement that has preceded the present. The materials are more brilliant, and the principle of arrangement more imposing, than anything that has previously existed; and the objections are raised, not against the beauty and effect produced, but on account of the evanescent character of the bloom. What is wanted is either to be able to prolong the season of blooming in autumn or secure it earlier in summer. Our climate renders the former impossible unless by a covering of glass. The latter, then, is what our hopes must rest upon in a popular point of view. If this be the case, it becomes a matter of no small importance to inquire whether it be possible, by any principle of management and arrangement, to have our flower-beds gay with flowers early in June that shall also last till frost puts an end to it in autumn. It is considered that this is attainable, and that, too, without adding much if anything to the labour or expense at present incurred in this department of our gardens. In most establishments the means and the end are sadly out of proportion in the flower garden as compared with other departments. If a gardener is expected to have crops of fruit he invariably expects to be supplied with proper means; but he does not hesitate to undertake the rearing of thousands of plants for the flower garden by any makeshift his brains can devise, and at planting-out time the plants are more an apology for plants than anything else. That by different management flower-garden plants could be made to produce the desired display of flowers at least a month earlier is a point on which I have no doubt whatever.

Let us take, for instance, the Geranium brigade of the great army of flower-garden plants, and see the great difference as to earliness of blooming that can be secured by different management to that makeshift system which is forced upon gardeners in so many instances at present. In some instances they have forced it upon themselves by an ardent desire to cope with more favoured neighbours, and from a mere love of the effect produced even for a short time. How often are Geraniums potted-off in spring when vineries and peach-houses are started, and from the high temperature of 70° and the shade of the Vines, are of necessity removed to sheltered shady corners under mats, wooden shutters, and even to trenches cut in the open quarters of the kitchen garden. Here they are hardened-off with a vengeance, and with an amount of anxiety and labour which the writer in "Once A Week" never dreamed of. All these methods I have myself adopted, and have besides shaken the plants out of cutting-pots and boxes, and planted them in the beds to be exposed to the drying breezes and hot suns of early summer, by which the green sappy leaves are turned brown in a day, and for the first month they get "small by degrees and beautifully less." As to bloom-buds or blooms there are none at planting time worth the name, and what few there may be (more by chance than good gardening), are soon done for; the tender foot-stalks are blackened and share the same fate as the foliage

To produce early bloom and rapid growth, it is not so much a large as a properly prepared plant that is required. If both can be had of course so much the better, but the preparation is of most importance.

If instead of this mode of treatment the plants are potted into three and four-inch pots in February, and subjected to just sufficient heat to start them, and then placed in houses or pits under clear sheet glass, and exposed on all favourable occasions to a free circulation of air and all the sunshine that can be had in a south exposure, how different is the result! We have short, stubby plants clothed with thick hardy foliage, and bristling with bloom, that make comparatively gay beds the day they are planted. This is no mere theory, but a fact, which, no doubt, can be strikingly illustrated by many cases. One particular instance of the great difference produced on the side of rapid growth and early flowering came within my own experience this season, in the case of a border wherein some seven hundred plants of variegated *Geranium Bijou* form part of the combination. It was desired that two of the lines should be planted with the largest plants of this *Geranium* that could be selected, and they were found in a house with an east exposure where they only had the sun for a short period of the day. In other respects they were here treated exactly the same as another lot of the same plant, which had a place in another house with an aspect due south, which, consequently, had all the sunshine that it was possible to enjoy. The plants from the east aspect were fine handsome plants, larger in all respects than those in the other house, and they had always been so, and were accordingly planted in the two back rows. The short, stiff, rustling plants from the influence of the full sun filled up the rest of the bed. Most of them were much less than the other set; but the result has been, that the small plants out-distanced the others in a very short time, and closed up, and were in full flower a month before the others.

Now, the big plants were by no means tender when planted, and they lost no leaves, and apparently received no check, but they made neither wood nor flowers half so quickly in the early part of the season as the others. Besides this, I might notice as corroborative of the above, the case of a large number—between eight and nine thousand—of the different varieties of the Zonale and plain-leaved *Geraniums*, which were potted-off in February, and placed in one large house, where they had no fire heat whatever. They stood not far from the glass, and were constantly exposed to all the sun and air which an efficiently ventilated and clear sheet-glass house could afford. When planting time came they were compact, sturdy plants, bristling with expanded and unexpanded blooms, and made gay beds the day they were planted. And I speak within the bounds of truth when it is stated that they were in their prime at least three weeks earlier than ever I could have them when put into vineries, and afterwards hardened-off on the makeshift system in sheltered corners under mats, shutters, &c. The labour and anxiety incurred were also wonderfully decreased, as compared with any temporary means which ever I could hit upon. There can be no doubt whatever, that in the case of one of our most prominent sections of plants, and in others, too, the blooming season is much longer when they are grown as detailed above.

It is also considered a point of considerable importance, as a means of selection, to select in autumn good, large, stiff cuttings, instead of the mere points of the shoots, and to strike them early. Before the middle of September the best cutting should be put in. Besides this, there is a great difference in favour of the cutting that is struck out-doors in the full blaze of the sun, as compared to a later cutting under glass.

In the case of *Verbenas* again, several weeks could be gained by making a selection of the varieties found to flower the earliest. In this respect there is a difference of several weeks in favour of some of the varieties. Generally speaking, the stiff compact-growing sorts, such as *Charles de Gaulle*, among the darks, and *Victoria Scott* among the scarlets and crimson, are much earlier bloomers than the strong trailing sorts. White beds could be much earlier in the season by using the *Cerastiums* in place of white *Verbenas*, which are generally late, and when in bloom cannot be compared to *Cerastiums* for a sheet of

white. In autumn, too, the white *Verbenas* give way, while the white-foliaged plants are in their glory. There are several varieties of *Arabis* (particularly *A. lucida variegata*), which are really beautiful for edgings; and in consequence of their standing the winter, and being fine when many other things are only being planted, are deserving of more extensive cultivation.

I have no doubt that in the course of years, and by judiciously agitating the subject, that the season of the flower garden will be greatly lengthened, independently entirely of the things now used in many places for spring decoration. And, oh! that we could hope for the time when in our giant establishments we shall see an acre or two covered with glass, if it were for nothing else than to bring out the real splendours of the fine varieties of *Geraniums* which we now possess. Very little conception can be formed of the effects which could be produced under glass with the great Nosegay and Globe varieties of *Geraniums*. A glass-covered garden for these alone would be an era in pleasure-gardening that would astonish us, if any judgment is to be formed from the effect which they produce in a small way long weeks after they are cut down with frost out-doors. In this direction an extension of the blooming season on a large scale can scarcely be looked for; and it is, therefore, all the more desirable that early blooming in the system now so much adopted should be aimed at, as well as the selection of those varieties which have their full effect early in the season, and which at the same time maintain it to the last. More particularly is this to be desired when such plants have invidiously been made the chief or only features of the parterre. The sooner the masses of our tender flowers which vanish with the first frost cease to be the alpha and omega of our flower gardens, the better in many respects; and if anything is wanted more than another, it is the genius which will so blend and intermingle them with beautiful varieties of evergreen trees and shrubs that they will prove important features in summer and autumn, and yet not be much missed when not there in winter. There is always a foreboding of dreariness which comes over the mind when looking at a mass of flower-beds in a sunk panel, or on a terrace, where there is nothing left when they are gone but bare beds of earth, or even broken bricks or bottles. They should be so placed and blended with something of a more permanent character, that their removal would be no more missed than the bracelets and jewels which ornament the naturally elegant and beautiful person when they are laid aside.

D. THOMSON.

THE AGRICULTURAL HALL FLOWER AND FRUIT SHOW.

THE Agricultural Hall, Islington, though only completed last year, is familiar to the public as the place where the Smithfield Club Cattle Show is held. There are few persons interested in rural affairs who do not make a point of being present at least once in two or three years at these great annual gatherings, where the townsman and the countryman meet each other to the amusement, instruction, and profit of both.

The Show had outgrown the old inconvenient building at Baker Street, and, to meet its requirements, a new structure was erected in the Liverpool Road, enclosing a space of 384 feet by 217 feet, and surrounded by galleries 36 feet wide, affording in all an area for exhibition purposes of nearly 3 acres. The roof has a span of 125 feet, and a height of 75 feet, and being of glass affords an abundance of light. It will thus be seen that the building is well adapted for a horticultural exhibition on a grand scale; and as this was a want in that wide and populous district, the north of London, it was determined to hold one. This determination, however, was arrived at too late in the season; the last of the summer shows was over, and exhibitors, expecting nothing more, took their measures accordingly. Had a list of the prizes offered been issued in sufficient time, doubtless a greater competition would have resulted; added to which the Exhibition was singularly unfortunate in the weather, for the flowers of many of the intending exhibitors were irretrievably damaged by the thunderstorm which visited the southern part of England on the Tuesday preceding. There were also some omissions in the schedule of prizes offered, which undoubtedly

tended to keep away exhibitors. There was also the still greater drawback that the Show was a new one, that it was not sufficiently known; and what probably acted still more to its disadvantage, it was to last three days—a period too long for gardeners to expose their most valuable plants to the unfavourable influences of a public exhibition. It was, then, probably, to all those causes combined, as well as to the size of the building itself, that the tables were somewhat scantily furnished, and that chiefly with fine-foliaged plants and florists' flowers, of which last, it need hardly be observed, an immense number will fill a small space. However, the Exhibition was but a first attempt, and any want of success in a horticultural point of view was amply compensated by the poultry department, of which a separate report will be given in another column. The weather, too, on the first day was very unfavourable, close heavy rain continuing to fall with but brief intermission throughout the time the Show was open, and this, doubtless, was the cause of a scanty attendance of visitors.

STOVE AND GREENHOUSE PLANTS.—The show of these was very inconsiderable, only three competitors coming forward—namely, Mr. Rhodes, of Sydenham Park; Messrs. A. Henderson & Co.; and Mr. Young, gardener to R. Barclay, Esq., Highgate, who stood in the prize list in the order in which they are here named. Mr. Rhodes had *Vinea alba*, *Allamanda cathartica*, *Croton saligna*, and three *Heaths*. *Vinea ocellata* in good bloom, *Allamanda cathartica*, a large pot of *Lilium lancifolium rubrum*, *Ixora coccinea*, *Brugmansia candida*, *Bilbergia splendida*, *Hedychium Gardnerianum*, and *Pancratium maritimum* were among the other plants shown.

FINE-FOLIAGED PLANTS.—These together with exotic Ferns constituted the principal portion of the plant exhibition, and among them were some excellent specimens. Mr. Williams, of Holloway, took two first prizes. Among the plants which he exhibited were a large *Calceasia Lowii*, *Dicksonia antarctica*, *Gleichenia spelunce*, *Livingstonia borbónica*, and *Dion edule*; and in another collection *Cibotium princeps*, the glaucous-leaved *Encephalartos Lehmanni*, and *Dracena indivisa* were noticeable. Messrs. A. Henderson & Co., were second both in twenties and twelves, having among others a fresh healthy-looking plant of *Cycas revoluta*, a large *Dracena ferrea*, *Dracena cannaefolia*, and *Alocasia metallica*. Mr. Young, of Highgate, who was third, had *Sansevieria javanica*, and three good *Caladiums*. Other collections from the same exhibitor contained some large specimen *Caladiums*, *Pandanus elegantissimus*, and *Sphaerostemma marmoratum*. Large plants of *Encephalartos caffer* and *latifrons*, and *Cycas revoluta*, also came from Mr. Taylor, of Highgate, who had third prize for twenty plants.

MIXED COLLECTIONS were shown by Mr. Williams and Messrs. Henderson. That of the former contained two very large specimens of *Dicksonia antarctica*, *Agave filifera*, *Anthurium acule*, a good flowering plant of *Allamanda Schottii*, and *Achimenes Mauve Queen*; and Messrs. Henderson had a small plant of *Alocasia metallica*, the young leaves of which shone with a beautiful metallic lustre; a good specimen of *Cibotium Schiedeii*, *Cissus porphyrophyllus*, a fine specimen of *Jacarandra filicifolia* which had been exhibited several times during the summer, an *Allamanda*, some *Ixoras*, and *Vincas*.

EXOTIC FERNS.—The best came from Mr. Williams, who had magnificent examples of *Cibotium Schiedeii* and princeps, *Gleichenias dichotoma*, *flabellata*, *spelunce*, and *semivestita*, the latter forming a beautiful mass; also, good plants of *Alsophila radens* and *Todea africana*. An excellent collection also came from Mr. Taylor, Mr. Young, and Messrs. Henderson, the first two taking the second and third prizes.

DAHLIAS were shown in splendid condition; those from Mr. Turner, which took the first prize in the Nurseryman's Class of 48, could not have been surpassed for size, form, and effective arrangement. There was not an indifferent flower among them. They consisted of *Midnight*, *General Jackson*, *Mauve Queen* (very fine), *Flower of the Day*, *Lord Derby* (rosy crimson), *Hugh Miller*, *Chieftain*, *Lord Elcho*, *Imperial*, *Caractacus* (yellow tipped with bright red), *Pauline*, *Lord Palmerston*, a lilac-mauve-tipped seedling, *Chairman* (yellowish-buff), *Mrs. Busk*, *Cygnets*, *Triomphe de Pecq*, *Mr. Boshell*, *Charlotte Doring* (white tipped with rosy crimson, very fine), *Andrew Dodds*, *Leopard*, *Dinorah*,

Lilac Queen, *Umpire*, *Beauty of Hilpertion*, *Disraeli*, *Model*, *Pioneer*, *Mrs. Henshaw*, *Una*, *Mrs. Elliott*, *Sidney Herbert*, *Golden Drop*, *Garibaldi*, *Norfolk Hero*, *Bob Ridley* (bright red), *Lady Popham*, *Commander*, *Perfection*, *Marion*, *Mrs. Vyse*, *Countess of Shelburne*, *Charles Waters*, *Earl of Shaftesbury*, *Lord Clyde*, *Mrs. Piggott*, and *Criterion*, the last a magnificent bloom $4\frac{1}{2}$ inches across. Mr. Keynes, of Salisbury, was second in the same class with excellent blooms, but not equal in size to Mr. Turner's. Among the best were *Lady Douglas Pennant*, *Andrew Dodds*, *John Wyatt*, *Charlotte Doring*, *Earl of Shaftesbury*, *Lord Russell*, and *Earl of Pembroke*. Mr. Cattell, of Westerham, was third with some excellent blooms, and Mr. Legge, of Edmonton, had an extra prize.

In the Class for 24 blooms Mr. Keynes was first, and Mr. Turner second, the difference between the two collections being almost inappreciable. *Baron Taunton*, *Lord Derby*, *Beauty of Hilpertion*, *John Wyatt*, *Lilac Queen*, *Charles Turner*, *Hugh Miller*, *Willie Austin*, and *Lord Russell*, were a few of the finest; and in Mr. Turner's stand, *Mauve Queen*, *Criterion*, *Bob Ridley*, and *Charlotte Doring*, were very fine. Mr. Cattell was third, and Mr. Legge had an extra prize.

In the *Amateurs' Class* the best twelve came from Mr. Moffat, gardener to Viscount Maynard, Dunmow. They were *Model*, *Joy*, *Lord Palmerston*, *Andrew Dodds*, *Umpire*, *Peri*, *Colonel Wyndham*, *Village Gem*, *Chairman*, *Lady Popham*, *Lilac Queen*, and *Mrs. Charles Waters*, all of which were fine. Mr. Wakeman was second; Mr. Perry, Castle Bromwich, third.

In *Fancies* Mr. Turner was first in the *Nurserymen's Class*. *Pauline*, *Nora Creina*, *Pluto*, *Zebra*, *Queen Mab*, and *Starlight* were some of the most striking; and Mr. Keynes was second. In the *Amateurs' Class* Mr. Perry was first; Mr. Barnard, gardener to Col. Eyre, second.

Several new kinds were shown by Mr. Keynes, as *Regularity*, *Earl of Pembroke*, *Surety*, and *Anna Keynes*, all of which have received certificates from the Floral Committee. *Sam Bartlett*, *Queen of Roses*, and *Willie Austin* also appeared very desirable sorts. Dr. Johnson, a large light scarlet, came from Mr. Harris.

HOLLYHOCKS.—From the greatly improved character of the newer varieties, both as regards colour and substance, this flower cannot fail to take a much higher position at our autumn shows than it has hitherto done; and it may safely be affirmed that it is steadily advancing in favour; and how worthy it is of more extended cultivation all who have seen the splendid blooms exhibited by Messrs. Downie, Paul, and Chater must readily acknowledge. On the present occasion Messrs. Downie had the first prize for *Premier*, crimson lake; *Golden Fleecce*, yellow; *Aurora*; *Mrs. Chater*, rosy carmine; *Joshua Clarke*, bright cherry; *Countess of Craven*; *Porter's Lord Childe*; *The Queen*; *Mrs. F. Mackenzie*, scarlet; *Mrs. Balfour*, crimson shaded with salmon; *Mrs. B. Cockrane*, rosy crimson; and *Invincible*, rosy salmon. Mr. W. Chater's had also splendid blooms, some of them being even larger than Messrs. Downie's, but they did not exhibit so great a variety in colour. Among them, in addition to some already named, were included *Princes*, *Beauty of Milford*, *Acme*, *Ariadne*, *Rosea Pallida*, *Queen Victoria*, *Argus*, and *Paragon*. Messrs. Paul & Son, who had the third prize, and Mr. Smail of Norwood, who received an extra prize, had also remarkably fine blooms.

ASTERS.—In the *Quilled* kinds a stand of very fine blooms from Mr. C. Sandford, gardener to T. Thomasset, Esq., took first prize; the second and third going to Mr. Grimby, Stoke Newington, and Mr. Ward, Tottenham. In *Tasselled* kinds Mr. C. Sandford was also first, all his blooms being large and exceedingly good—some measuring $3\frac{1}{2}$ inches across. Mr. W. Sandford, Woodford Bridge, and Mr. Ward, were second and third, both their exhibitions being likewise excellent. Messrs. Cutbush contributed in addition some well-grown plants, about 18 inches high, in pots.

GLADIOLUS.—A box containing good blooms of *Brenchleyensis*, *Madame E. Verdier* (very fine), *Goliath*, *Fanny Rouget*, and *Oshris*, came from Mr. Cattell and received a first prize.

PHLOXES.—Mr. Turner was first for these, showing some immense trusses, and the flowers being individually large. *Orphée*, *Oriana*, *Mrs. Standish*, *Comte de Chambord*, *Julie*

Roussel, and Madame Vilmorin, were some of the finest. Mr. Cattell was awarded the second prize.

MISCELLANEOUS.—Messrs. Perkins & Sons, of Coventry, and Mr. Perry, had some excellent trusses of *Verbenas*, for which both received prizes; and Messrs. Paul & Son eight fine boxes of *Roses*, some of which, as *Senateur Vaisse*, *Comtesse de Chabrillant*, *Catherine Guillot*, *Général Jacqueminot*, and *Madame C. Crapet* were very fine.

Prizes were offered for table decorations, and the highest award was taken by Mrs. Cutbush, of Highgate, with March's stands elegantly filled with flowers and fruit. The two outside stands had *Peaches*, *Nectarines*, *Apples*, and *Pears* at the base, resting on fronds of *Lastrea Filix-mas*, and interspersed with the lively green of *Adiantum emarginatum*. *Lycopodium cespitosum* was twined gracefully round the upright glass stem, and the top dish had *Fuchsias* and *Capsiums* depending from the edge; whilst the central portion of the dish itself was filled with white *Roses*, scarlet *Verbenas*, white *Jasmine*, and *Heliotrope*, with some *Adiantums* interspersed. The centre stand had flowers at the base and fruit at the top; the former consisting of *Scarlet Geraniums*, *Heliotropes*, *Verbenas*, and *Lisianthus*; the latter of *Black and White Grapes*, *Apples* and *Plums*, surmounted by a *Pine*, whilst *Lycopodium* twined up the column. The design balanced well from all points of a view, and did credit to the taste of the lady by whom it was executed; and she further contributed some bouquets, one which, consisting wholly of white flowers and *Adiantum*, was extremely modest and graceful. Mr. Robson, of Linton Park, also exhibited a design for table-decoration, for which he received the second prize. This was also in glass stands; the central one, instead of having an upright column, had a stem which branched at a little distance from the base into two semicircular arms, which reunited beneath the dish at top; and within the circle thus formed the base portion of the stem was continued upwards a short distance to support another small dish. In this a white *Magnolia* was placed, a *Pine Apple* at top, and *Rose-hulls*, *Japan Lilies*, golden variegated *Geranium* leaves and *Ferns* at the base; whilst the two end stands, on the contrary, had fruit at the base and flowers at top.

FRUIT.

Prizes being offered for out-door fruit only, the "king of fruits," *Melons*, and the splendid examples of *Black Hamburg* and other *Grapes*, which we look for at a horticultural exhibition, were excluded, and their absence spoilt the effect of the display, more especially as it was too early in the season to expect much in the way of out-door fruit.

Mr. Morris, gardener to A. Bosanquet, Esq., Southgate, had the first prize for a collection of *Apples*, *Peaches*, *Washington*, *Victoria*, and *Green Gage Plums*. Messrs. Cutbush and Son, second, for *Kerry Pippin*, *Jargonelle Pears*, *Peaches*, *Nectarines*, *Green Gage Plums*, and *Sweetwater Grapes*. Mr. Turner also received a prize for a collection consisting of *Peaches*, *Apricots*, *Plums*, a *Melon*, *White and Black Grapes*, and a *Pine*.

PEACHES.—Mr. Turner had *Walburton Admirable*, *Belle-garde*, *Noblesse*, and *Padley's Royal*, for which he received a first prize; and he had a similar award for a dish of *Walburton Admirable*.

NECTARINES.—Mr. Rutland, *Garnstone Castle*, was first in four dishes, with *Ehrage*, *Roman*, *Duc du Telliers*, and *Brugnon*. Mr. Turner was second; and in the Class for single dishes he had first prize for some fine fruit of the *Pitmaston Orange* very highly coloured. *Newington* from Mr. Heppar, *Dulwich*, had equal first.

FIGS.—In three dishes Mr. Turner had first prize for good dishes of *Brown Turkey*, *Brunswick*, and *White Genoa*; and Mr. Moffat was first in single dishes with *Brown Turkey*.

CHERRIES.—Excellent *Morellos* were shown by Messrs. Turner, Lane, and Earley, to all of whom prizes were awarded.

PLUMS.—In four dishes, Messrs. Lane were first with *Magnum Bonum*, *Washington*, *Goliath*, and *Green Gage*. Mr. Turner second, with *Washington* and *Jefferson* (fine). *Victoria*, and *Goliath*. In single dishes Mr. Turner was first with *Green Gage*; Mr. Beasley, *Twynford Abbey*, second, with the same kind; Mr. Newton, gardener to G. J. Graham, Esq., *Enfield Chase*, third.

APPLES.—In desert kinds Mr. Turner was first with *Nonsuch*, *Cox's Orange Pippin*, and *Small's Golden Pippin*.

Mr. Moffat second, with *Cox's Orange Pippin*, *Kerry Pippin*, and *Golden Russet*. Some good dishes were also exhibited by Mr. Newton and Mr. Earley. In kitchen kinds, Mr. Wright, *Twickenham*, had first prize for *Golden Noble*, *Hollandbury*, and *Hawthornden* (fine). Mr. Lane, *St. Mary's Cray*, was second.

PEARS.—Mr. Turner was first with *Williams' Bon Chrétien*, *Jargonelle*, and *Fondante d'Automne*. Messrs. Lane second, with *Beurré d'Amanlis*, *Charnock*, and *Jargonelle*. Mr. Earley was third; and Mr. Newton had also good dishes of *Windsor* and *Marie Louise*.

MISCELLANEOUS.—Messrs. Lane had numerous fruit trees in pots loaded with fruit, and consisting of *Figs*, *Plums*, *Cherries*, *Apples*, and *Pears*. They also exhibited dishes of *Apples*, excellent *White and Red Grape Currants*, and *Plums*, of which the *Washington* was very fine. Mr. Turner had a beautifully-netted *Golden Perfection Melon*.

We cannot conclude without paying a just tribute to the uniform courtesy which Mr. Douglas brought to the task of carrying out the arrangements of the Show—a task all the more onerous that the Show was a new one, and that, therefore, there was not the experience of previous years to guide the judgment. The experiment of holding a horticultural show for North London could not be considered a success as regarded the number of visitors it attracted; but if repeated at another period of the year, and when its existence shall be better known, it will, probably, be attended with greater success.

LOBELIA KERMESINA AS A BEDDING PLANT.

This charming bedding plant has hardly received the attention it deserves. We have few bedding plants of the same colour, and none that are less spoiled by rain.

It is propagated with even more facility than *L. speciosa*, but is more delicate than this latter. Plants of both were pricked out early in April in a sunk bed, and covered with boards at night, and *L. kermesina* suffered much more than did the other from exposure, &c.

The cuttings should be put in as early as possible, as it is rather late in coming into bloom, and in planting out it will be found advantageous to stick little twiggy branches about 3 inches high all over the bed, because it grows in such a tight little clump that without some such support it is apt to topple over when there is a high wind.

I may mention the planting of one bed in which I have it, as most people who have seen it have liked it. It is a star of eight points. In the centre there is a clump of tall *Lord Cottenham Geranium*; round this a circle of *Zelinda Dahlia*; next two rows of *Flower of the Day Geranium*, which reach down to the edge of the spikes of the star. Each alternate spike is planted with *L. speciosa* and *L. kermesina*, and the apex of each has a good plant of *Golden Chain Geranium*. The effect is very good.—Q. Q.

ARRANGEMENT OF INTERIOR OF A GREENHOUSE.

I HAVE just had a greenhouse erected, 16 feet by 12, span-roofed, and I wish to have a railed shelf all round it, instead of the old-fashioned stages. The height of the brick-work and wall-plate is just 2 feet. Is not this too low for the railed shelf? What height would you advise it to be made, and is 3 feet sufficient in breadth for such a sized house? I suppose the breadth and height are according to taste, but I should be very much obliged if you would tell me what height you think would show the flowers to most advantage.—G. F. W.

[If you had given us the height of your house in the centre, we should have been better able to advise you. We must presume that that is from 6½ to 9 feet, and if so, the roof will be steep, if the side walls are only 2 feet. So far as the plants are concerned, however, that will make little difference. If there is 3 feet from the ground to the wall-plate, and you propose to have a shelf all round, at least on the sides, that would give you more room for storage beneath the shelf than in the case of a two-foot wall. We are supposing that the lights on each side rest on that wall. In

that case, we would have the shelf 8 inches or so below the level of the wall-plate, which will allow plenty of light for the plants, and yet screen the pots from the direct action of the sun's rays. The lower your shelf the better will you see the plants, and the less will you see of their pots. Did you want to make the most of the shelves, and have only a path in the middle, you might make each of them $4\frac{1}{2}$ feet wide, and that would leave you 3 feet for walk in the centre. Then over that, if the roof was high enough—say 8 or 9 feet, you might either have a shelf or baskets, &c., suspended. The only drawback against this plan would be, that in a platform formed either of wood, or a border of brick and earth, and ashes for the bed, the width is too great to enable you to see and handle all the plants conveniently from the passage. Still, as a mere repository for growing plants, the arrangement would be a good one.

For mere show, the proposed width of $2\frac{1}{2}$ to 3 feet for your shelves would answer better, and the height of these may be regulated so as to be below the wall-plate just 6 or 8 inches, and then you would require to keep low plants in front. In fact, were your house only $6\frac{1}{2}$ feet or so at the ridge, you would need no shelves at all. The pots might all be on the ground level. In this case, with such narrow platforms, you would have from 6 to 7 feet of pathway; but in that you could set tall plants on the floor, and so arranged as to prevent monotony.

But for your objection to a centre stage or platform, we would have the side walls at least $4\frac{1}{2}$ feet high, the ridge 9 feet, a shelf all round 2 feet wide, and a table or platform in the centre 4 feet wide, with a two-foot walk all round. In such a case we would make the front platform and the centre 15 to 18 inches below the ridge-board.

Did we want not merely to grow but to show the plants off in such a house to the greatest advantage, then we would make a different arrangement. Suppose your walls at the sides were $2\frac{1}{2}$ or 3 feet to the sill, then we would put $2\frac{1}{2}$ or 3 feet of upright glass between that and the wall-plate; height at ridge 9 or $9\frac{1}{2}$ feet. Then suppose this house was at the end of a drawing-room, or the door of a dining-room or parlour, as soon as the door in the centre of the end was open, you might see the plants at once to the best advantage. We would not have a shelf or a level platform, but a sloping stage on each side $4\frac{1}{2}$ feet wide, the highest shelf of which would be next the wall-plate, and the lowest shelf close to, if not formed of the floor next the pathway. Only a few of the taller plants at the sides next the upright glass would be above the eye. The great proportion would be under the eye, and as you looked down on the banks of flowers and foliage on each side, little of the pots could be seen. The great amount of light in low span-roofed houses will prevent the shortest plants near the pathway in the centre being drawn. Although we have spoken of banks of flowers, there is no necessity for having them uniform, as they may be thrown every week into fresh combinations. In looking at such plants from a slight elevation, or merely from the level floor, the effect is much more striking than when you must look up to them on a level platform, or a merely raised stage, as the more the stage is raised just so much the better are the pots seen. This plan can scarcely be followed successfully unless there is side glass, as well as the top lights. We would advise our correspondent to try the effect of such an arrangement before fixing her shelves. High plants at the sides, and low plants close to the path in the centre, would show the effect at once.—R. F.]

COMBINATION OF GREENHOUSE, STOVE, AND PITS.

In your Number of July 21st is a very neat forcing-house which I think could be turned to great account, but it is not delineated sufficiently for me. I want to have a lean-to house, and I could make an outside border for Vines if I choose.

First, I want a border all round to be heated as you describe; but what width could I make it to be heated sufficiently, and what is the leaf mould to rest upon, and what depth of water would require to be in the tank? Would the tank require to be often supplied with water?

If so, I think this would be most troublesome. Would not Caithness sawn pavement cemented make an excellent tank for the water for top moisture, also for sides next walk? Then I could have the centre of the house for plants standing on either a cold bed or stage, and no earth.

What would be the most substantial material for the house, wood or iron? I want it 30 feet long. I would require it to be from 12 to 14 feet in width within. What height should I require to make the back wall above ground level for such a house? My aspect would be south-east. What width would the paths be? Would a single pipe running through the tank be sufficient to heat it? What size of pipe would it be necessary to run through it? Would the path require to be elevated to let the pipe run through it to the border? What would be the cost of heating such a house? What would be the cost of a lean-to house made of Memel Pine, the wood part, of course, all plain—no ornamental work?—J. O. G.

The plan at page 51 of this Volume is very good for a combination of greenhouse, plant-stove, and pits outside, heated; but unless our employer allowed us and wished us to dip deep into his pocket, we should not think of such an arrangement for a viney, though no doubt it would answer well enough. We have the other week given some instructions on tank-making. It matters not what they are made of—stone, slate, or wood—if made watertight. We have seen wood $1\frac{1}{2}$ inch thick last more than twenty years. The wood was well beat at the corners, as for a brewer's cooler, and placed firmly together with red or white lead; and water being always in it there was no chance for leakage. We think the pipes through the tank a good precaution, though not absolutely necessary. If your tank is securely covered, you get no more top moisture from a tank than from a thick metal pipe. If you wish vapour from the tank or steam, you had better leave places to open for the purpose, and, of course, these must be shut when you wish for a dry heat. But now, if you merely wished a viney 30 feet by 14, and the border outside to be heated, we should simplify the whole affair and have nothing to do with tanks. Allow us, however, to say that heating your border outside will be of little use unless you can cover it with glass or tarpaulin, &c., with litter below it. Now, for such a lean-to house, 14 feet wide, we would have the back wall 12 or 13 feet in height, and the height in front, with wall and glass, 6 feet—half wall and half glass. In such a place we would build the back wall of fourteen-inch work, hollow. Then, if we must grow the Vines in such a house, without an outside border, and early Grapes were a chief consideration, we would take out the earth to the depth of 3 feet; concrete the bottom; place three four-inch iron pipes, about 90 feet, for bottom heat; leave them in a chamber 1 foot deep, cover with slate or stone, and then the soil above; or cover over the pipes with a foot of loose rubble and brick-work, then finer gravel, and afterwards the soil. Openings from that chamber into the house would be desirable. Then for the top heat, for early forcing, you would need about 120 feet of four-inch pipe. If Vines are planted at the back wall of such a house and then trained down the roof, you will be thoroughly independent of all outside borders, and, to a great extent, of all outside weather. Had we the chance of building an early viney, we should follow something like the above mode.

Exactly the same mode may be followed even with the help of an outside border, and that may be made in the same way. In your climate we would decidedly recommend inside planting, even though you plant your Vines in front in the usual way. In that case your front wall should be on piers or on arches; and then suppose that your inside border is 5 feet wide or so, you might make the outside one 6 or 7 feet wide, and to be heated in the same way. Mind that below the concrete there should be means taken for thorough drainage. For late Grapes coming in in autumn there will be no necessity for heating the border at all. For bringing them in in May it will be a great advantage, and the good substantial four-inch pipe is the best material for doing it with, such as may be had from 9d. to 1s. per foot. The great point to make sure of in such an arrangement is to see that the inside border is an inch or two higher than the outside one. On such a plan the border outside will make a capital pit to be covered with glass, and it will be

very useful for salads and other things in winter. In spring pot plants should be watered carefully in such a pit, so as not to soak or puddle the surface of the border; and in summer and early autumn it would be well to have nothing in the pit at all, in order that the sun may beat unobstructedly on the soil.

If you prefer a tank, and it is all sound and kept close at the top, it will want replenishing with water very seldom. If out of sight, the best plan is to have a gauge-stick in it standing in an open pipe, and that supplied with bung, and the appearance of the stick will always show the depth of water, and through that tube or pipe water may be supplied at pleasure. If you leave open spaces in the tank, of course the water will go off by evaporation, and a fresh supply must be given. The same holds true as to pipes. The fresh supply will chiefly depend on what is lost by evaporation. Of course, if the water is forced out by expansion by heat, fresh water will be needed, as that in the heating medium has cooled.

You are more likely to know what Memel timber will cost in your neighbourhood than we can tell you. Frequently in our advertising columns the price of lights for houses is given. The more jointed the wood and the smaller the glass, the more the expense for wood. The cheapest way for such a house would be to have a fixed roof—no sashes, but strong rafter sash-bars. If the place is much exposed, perhaps it would be advisable not to have glass above 10 or 12 inches wide; but even with a fixed roof, and the rafter sash-bars 10 inches apart, you would want double the wood that Mr. Rivers uses with glass 20 inches in width. The cost of timber, therefore, depends entirely on matters of detail.—R. F.]

THE GRAPERIES OF MR. MEREDITH AT GARSTON.

THE fashionable suburbs of a large town often present many features of interest to the tourist. Dwellings more or less commodious, and all more or less ornamented externally, give tokens of the wealth and comfort that reign within; while the diversity of taste by which one villa or residence contrasts with its neighbour, affords many a lesson which it would be well to study. That occasional deviations from good taste meet the eye cannot be doubted; but these cases are so few that they may be taken as the exceptions of rare occurrence. And contemporary with the architectural display evinced in the dwelling-house and its appendages, as the fences, gates, &c., the plot of ground facing the public highway has often claims to notice which call for something more than a careless approval; and, perhaps, no branch of cultural art has made greater advance than the one which has worked so much improvement in the limited plots of ground that many occupiers only possess. It is certainly creditable to all concerned, that the small plots alluded to present so many features of interest, and, though often differing widely from each other, they are all, nevertheless, beautiful, and many of the most important features of ornamental gardening are represented here—as the bedding system, rockwork, shrubbery, and very often a glass structure, and all carefully and studiously managed. That such houses are sources of unalloyed pleasure to the man of business after the mental toil of the day is over cannot be doubted; and their external appearance leaves little doubt that the interiors are equally well furnished with every requisite for comfort.

The moral bearing of these villa homes might be dilated on to some length; but it is needless to pursue the subject further than to say that such dwellings abound on the fashionable outskirts of most, if not all, of our large commercial and manufacturing towns, of which Lancashire presents as many as, perhaps, any other county, not even exempting the metropolitan one. And as most towns have their "west end," or fashionable side, in like manner has Liverpool, although in its case it is the east and not the west side.

The pretty village, or rather town, of Garston forms one of those beautiful suburbs to the great shipping city of the west coast by which it is connected by a long chain of villas, forming, as it were, a continuous street of some four

or five miles. Many of them are hidden amidst healthy and vigorous-growing trees and shrubs, showing, that although they are but a very short distance from the Irish Sea, the soil, climate, and other conditions favourable to their growth are tolerably abundant; and I confess being agreeably surprised to find this the case, as the highway from Liverpool to Garston rises about parallel with and but a very short distance from the noble estuary of the Mersey, which at Garston seems two miles wide or more. That much of the verdure found here is in a measure due to the shelter from the south-westerly gales which the Cheshire hills on the opposite coast afford I have no doubt; but it is not my place to enter into the question, but to point out one of the features of a neighbourhood where one of the most successful Grape-growers of the day has located himself. As the gardening world must be familiar with the name of Meredith, of Garston, and his Grapes, a few notes on the situation and the other features of his extensive and interesting glass structures and grounds will, no doubt, be acceptable to the general reader.

On the outskirts of the village of Garston, and about half a mile or more from the northern shore of the river or rather bay of the Mersey, Mr. Meredith has fixed his vineyard. The situation is one of those slight elevations which merely afford sufficient fall for what drainage might be wanted from stokeholes and such places, the ground of the district generally being of that slightly undulating character which distinguishes it from the flat rich pasture lands which border the river Mersey in the upper part of its course. The soil, too, at Garston is much paler in colour, though in its component parts it seems to contain as much sand as is found in the rich market-gardening districts to the north of Altrincham and elsewhere. The subsoil seemed a dry compound, of which sand rather than gravel formed the most important part. It certainly was not of that hungry pernicious character which some sandy or gravelly subsoils often are. On the contrary, I should say the subsoil was, perhaps, as agreeable to vegetation as any which I ever met with that did not contain stone; for, be it observed, that many stony subsoils are the favourite abode of tree roots, even when the surface soil is a good one; but in the case of those at Garston, from what little I could hear, I should think that stone was but very sparingly met with. At the same time I believe the subsoil contained within itself all the elements necessary for effective drainage; but whether additional modes of carrying off the superabundant moisture from the various borders existed or not, I am not prepared to say.

I may here observe that the whole of the glass houses were, with very few exceptions, devoted entirely to the cultivation of the Grape Vine; and when I say that there were upwards of twenty such houses, and many of them of large size, besides pits and smaller structures, it will be easily supposed that Grape-growing on an extensive scale was being pursued. Most of the glass houses were new, the oldest, perhaps, not being more than six or eight years old, while some were of more recent date; and two new ones of the present year, each 144 feet long by 28 feet wide, were not quite finished, although nearly so. These fine houses, of which some notice will be taken hereafter, were, nevertheless, occupied, as were all the others, with the favourite plant which seemed to thrive so marvellously under Mr. Meredith's care.

There is nothing remarkable in the structure of the houses, the most of them being span-roofed, the site not affording a high garden wall to lean them against, as is often the case in private places. The ground was in a great measure covered with span-roofed houses, placed in some cases parallel to each other, and at a convenient distance apart to allow sufficient room for the borders. The glass used was in some cases rough plate, and in others sheet, the squares generally large, though not remarkably so; whilst the pitch of roof, mode of ventilation, and other features differed but little from those to be met with elsewhere. Some mechanical ingenuity certainly was shown in the movement of the ventilation by a crank-rod that was not so much paraded in view as some similar contrivances are; but with the exception of the workmanship being good, useful, and plain, there was nothing in the outward character of the houses that differed from the generality of glass

houses of modern build. I may also add, that I believe the boilers used in heating them were mostly modifications of the saddle; and the pipes, bends, and other appurtenances such as are generally met with elsewhere. Most of the span-roofed houses had a pathway down the centre, and the hot-water pipes were but very little elevated above the floor.

Having given the above rough outline of the situation and character of the houses, it is now necessary to say something of their contents. Unfortunately, through an inadvertence on my part, I did not take such particular notes as I would have done had I thought of afterwards committing them to paper; but the character of Mr. Meredith's Grapes is so well known at the great shows in the kingdom, that it is needless to say more than merely advert to them. Suffice it to say, that those Vines which had attained something like a three or four-years' growth were loaded with the finest possible fruit. In fact, many growers for private use only, and not for exhibition, would regard the crop as imprudently heavy. Other houses a year or more younger had also good crops, and even some Vines recently planted had been allowed to bear a bunch or so; the vigorous health of the plants, Mr. Meredith seemed to say, making up for all the work they were at this early age called upon to perform. Certainly, now and then a young Vine was exempted from such hard working, but nothing like an exemption of the present year's work for the sake of another one was observable anywhere—every cane capable of bearing having its quota of fruit, and all in the most excellent condition, the youngest Vines, of course, being exempt, a vigorous rather than a rampant health pervading all. Rarely any of those long-jointed canes were to be seen which are so often met with elsewhere in newly-planted Vines, when enriching rather than good solid and suitable food is supplied them; for, be it remembered, although all the foliage presented the most luxuriant health, I do not remember noticing any of it approaching the dimensions I have heard some growers boastfully assert they have grown Vine leaves to. I mention this as a significant fact that extreme luxuriance of foliage is not wanted, neither is it always a token that the Vine is in the condition to produce the best fruit. This view of the matter was never more forcibly illustrated than in the Vines I saw at Garston, for although it would be impossible to point out finer fruit anywhere, the foliage did not in any case approach so near that of the Rhubarb as I have heard the leaves of some Vines compared to, when in point of fruitfulness they were second to those here mentioned.

As above stated, the Grape-houses presented every aspect, and it might be supposed that there might be a favourite one where the fruit attained greater excellence than in the others, but I failed to detect this—in fact, there did not appear to be any difference; and to those who may be curious in such matters, I may say that one of the few lean-to houses was placed against the east side of Mr. Meredith's dwelling-house, and, consequently, soon after midday it received no sun whatever, and yet the Grapes in this house were beautifully grown and coloured. A bunch of Black Hamburgs, which I hope to hear of figuring well at some of the shows, could not be much short of 4 lbs. in weight and well coloured, and this with a forenoon sun only. A similar house on the west side was later, but promised to be quite as good, the fruit being equally promising, as, in fact, were all the graperies. Some of the houses were devoted to one variety only, some mixed, and some to kinds requiring a greater amount of heat, or a different treatment from their neighbours, all showing the best possible result.

Of the kinds grown I regret not taking more particular notice, but I believe all the popular kinds of the day are well represented at Garston, several varieties of Black Hamburg and Muscats being found there; while separate houses were devoted to the late kinds, as Lady Downes' and Alicante, both of which seemed to be favourites with Mr. Meredith, but by no means to the extent of depriving other kinds of their due need of attention, for all were fairly and successfully grown. But to give every Grape a more fair and equal chance, Mr. Meredith has recently added the two large span-roofed houses above alluded to, the one being for all the varieties of White Grapes, the other for Black ones; and our readers may easily conceive the noble appearance these houses will present in a year or two, when they reflect that each house would make half a dozen good-sized Grape-houses,

for the length of both of these two houses at Garston was 144 feet, and the breadth 28 feet. A spacious pathway went down the middle, the roof being partly supported by a row of pillars on each side of the path. The roots of the Vines had access both inside and out, but were planted inside. The greater part of one of the houses was planted, and the Vines were doing remarkably well; the other was not so far advanced. Many new kinds were pointed out to us as on probation, and older well-known names were also included, and we should say that when these houses are once in a bearing condition, no better lesson in Vine-culture could be found in the kingdom than they alone will present, and the student in gardening will do well to make a journey there on purpose to inspect them. Even at the present time the various stages of growth at which the Vines are seen, coupled with the magnificent fruit and the great extent to which they are grown, render this remarkable place more interesting than all the glitter of the largest bedding-out place; for be it remembered, that most, if not all of the kinds known to modern cultivators are grown here on an extensive scale, and some new kinds of promise are on trial which may figure in a high position hereafter.

Amongst others of this class we noticed a seedling presenting a very large bunch, somewhat in the way of the White Nice, but Mr. Meredith says of much higher merit. This seedling had all the appearance of a good keeper, a good bearer, and the property of ripening earlier than some of the kinds of its class, which have little to recommend them but their size of bunch. We shall be anxious to learn further of this seedling, as it evidently is an improvement in a direction that wanted amendment, and we have no doubt but Mr. Meredith will offer it to the world in due time, and if it receive his approval we need have no hesitation in accepting it as good.

Some other seedlings and new kinds were on trial, and I need hardly add that all the old and popular varieties were extensively grown, as the Trentham Black, Frankenthal, Morocco, Black Prince, and the many synonyms by which some of the well-known varieties are called elsewhere. Even those difficult to grow, as Josling's St. Alban's, and others, had a place assigned them, and were doing well, showing that with judicious care and the necessary means much may be accomplished.

VINES IN POTS.—It will afford no surprise to be told that the Vines grown and kept in pots at this remarkable place are quite on a par with the extensive houses at command for that purpose, and some hundreds of canes were pointed out that were quite fit for forcing next season that had been raised from the eye the past spring. Others still more robust were, I believe, last year's plants cut down in spring, while others for that purpose were coming on. Most of the newly-erected houses contained Vines in pots, mostly in the most robust health, either for forcing in pots or planting-out when wanted.

Our readers will understand that Mr. Meredith is a builder of hothouses, and occasionally superintends the building of others when done by private hands; consequently, when he has to furnish a house with Grape Vines, it is needless to say he is in a position to do it in the best possible manner; and it would almost astonish the ordinary observer where all the Grape Vines so prepared at this establishment could be wanted.

Mr. Meredith, however, we are informed, is in extensive practice; and the old adage of a good thing needing no recommendation being applied to his Grape Vines, we expect a visit later in the winter will find his stock thinned to a considerable extent. To those, however, about building new Grape-houses, and furnishing the same with plants best suited to their wants, as well as to give the best advice on the all-important subject of making the borders, Mr. Meredith, living in such a central situation as Liverpool, cannot fail to be of the greatest value. The condition of certain Grape-houses, altered and renewed by him in places elsewhere, attest his skill and ability that way; while the exceeding simplicity of construction of the houses, and apparent homeliness of the substances used in the border-making, give every reason to believe that Mr. Meredith is in no way extravagant in his mixtures or compounds. I here mention this so as not to deter any one from consulting one so eminently successful under the idea that they were

likely to incur a serious expenditure in carting materials from some very distant place; for few, if any, have ever yet brought a chemical knowledge of the component parts of soils and the requirements of individual plants to bear so well on their cultivation as has Mr. Meredith; and his knowledge will enable him to pronounce whether such a soil will suit the Grape Vine or not, apart from all those outward appearances which are the only guide to a less practised hand. The uniform courtesy with which he receives and communicates his ideas to others in the craft cannot be too highly extolled. As to my friend (a nobleman's gardener) and myself, no information of any kind was withheld, and the visit to Garston will long remain as one of the red-letter days not to be forgotten.—J. Robson.

SOME OF THE GARDENS WORTH SEEING IN ABERDEENSHIRE AND BANFFSHIRE.

WILLING to assist in directing those who have a pleasure in seeing gardens, I forward a list of gardens worth seeing in Aberdeenshire and Banffshire. Some of the places have natural scenery far surpassing anything of the kind I have ever witnessed:—

ABERDEENSHIRE.

Place.	Proprietor.	Gardener.	Town.
Slains Castle	Earl of Errol	Unknown	Peterhead.
Pitfour	Admiral Fergusson	Mr. Smith	Mindaw.
Ellon Castle	A. Gordon, Esq.	Mr. Howitt	Ellon.
Strichen House	G. Baird, Esq.	Mr. Hossack	Brucklaw.
Dunecht	Earl of Balcarras	Mr. Farquhar	Aberdeen.
Fyvie Castle	Captain Gordon	Mr. Farquhar	Fyvie.
Keith Hall	Earl of Kintore	Mr. Donaldson	Inverury.
Troup House	F. Campbell, Esq.	Mr. Dalloch	Fraserburgh.
Huntly Lodge	Duchess of Gordon	Mr. Aitchison	Huntly.
Balmoral Castle	Her Majesty	Mr. Paterson	Aboyne.
Aboyne Castle	Marquis of Huntly	Mr. Sturry	Aboyne.

BANFFSHIRE.

Place.	Proprietor.	Gardener.	Town.
Duff House	Earl of Fife	Mr. Mackie	Banff.
Cullen House	Earl of Seafield	Mr. Petrie	Portsoy.
Gordon Castle	Duke of Richmond	Mr. Webster	Tochabers.

The best time to see gardens in this part of the country is the months of August and September. The places named are all within easy distance of their respective railway stations.—J. H.

[We wish every reader of our Journal would send us a list of the gardens worth visiting in any county, with the names of proprietors and gardeners when known.—Eds. J. of H.]

GLADIOLUS DISEASE AND NAME.

AN inquiry was made in THE JOURNAL OF HORTICULTURE of August 11th regarding the disease which has attacked the Gladioli so much this season. It has been most prevalent in this neighbourhood, particularly in the dry sandy soils; we, therefore, may conclude the disease does not arise from damp or excess of moisture, as is sometimes supposed. On the other hand, I am inclined to believe that the unusually dry spring has in a measure aggravated, although it cannot have caused, the disease, it having appeared to some extent both in wet and dry seasons.

It is certainly a great drawback to the general cultivation of so showy a flower, for nothing can be more disappointing and nothing more unsightly than the diseased plants, the leaves of which, and in most cases the whole plants, have to be cut away to preserve the neat appearance of the bed.

As "D." of Deal, has had some information lately about the bulb from M. Verdier, and visited the chief growers on the continent, he may, perhaps, be able to prescribe a remedy.

Mrs. London speaks of the bulbs being left in the ground from year to year, "and that at Spofforth in Yorkshire, where the soil is a rich yellow loam, there are clumps of Gladioli which have been left in the ground undisturbed for more than twenty years and which bloom magnificently. Similar treatment is given to the beds of scarlet Gladioli in the garden at Blair Adam, in Scotland, which are very splendid."

I am not aware whether all the varieties are equally hardy; but twenty years ago there were few in comparison

with what we have now. Whether the experiment of leaving them in the ground would be worth trying we should be glad to know.

I should also be glad to know, now we are on the subject, the proper pronunciation of the word "Gladiolus." I have heard so many conflicting opinions that it would be rather a relief to have the matter settled. The accent is often put on three different syllables thus:—Gladiólus, Gladiólus, and Gládiolus; the first is most common and the most incorrect; the second is the pronunciation generally supposed to be correct, and the way we believe Mrs. London accents it. I have, however, been corrected in that; and I find from various Latin dictionaries, Ainsworth, Riddle, Andrews, and others, that the accent should be on the first syllable, thus—Gladiólus, or rather that there should be no particular stress on either, if it were possible to pronounce the word without; but the little accent used should be placed upon the first syllable, *Glad*. We have more authority for this than any other way; therefore, conclude it most correct, but I should feel obliged for a little information on each of the above queries.—R. T. E., *Shrewsbury*.

[There is no doubt as to the proper pronunciation of the name. It is *Gladiólus*, as if there were no *o* in the spelling, and the accent on the *i*.—Eds. J. of H.]

BATTERSEA PARK.

HAVING heard of the rare plants that were bedded-out here I was induced to pay it a visit on the 23rd ult., and was agreeably surprised to see how well the materials of landscape-gardening were worked out by Mr. Gibson, the superintendent.

All who recollect the difference between the present diversified and the former flat surface must be delighted with the pleasing variety produced by the mounds formed of the dredgings from the river Thames, by which depth is given to the river, and mounds and slopes of artificial beauty to the Park. The effect has also been heightened by the introduction of large trees which had been planted individually and in masses in the autumn, and are now looking well. The lake is also an interesting feature, which has lately been improved by more irregularity in parts of its outline to produce variety.

After entering the Park from the Chelsea New Bridge I turned to the left, and proceeded westward along shrubberies and borders edged with *Lobelia speciosa*; then *Nierembergia gracilis*, which does not fill up the space allotted to it well; then Scarlet Geraniums, backed by Dahlias. The broad mass of the light green foliage of Pinks, edged with *Lobelia speciosa*, looked well on the left side of the walk.

The next scene on the walk leading to the right presents a row of Dahlias to the back; then *Calceolaria Aurea floribunda*, edged with *Nepeta amethystina*, and further on four rows of Crystal Palace Tropaeolum, edged with *Cerastium tomentosum*, with an opposite of double white Feverfew and Tropaeolum. Then around the shrubberies to the right and to the left are Dahlias, double white Feverfew, and Nosegay Geranium, edged with *Cerastium tomentosum*.

Opposite the steam-boat landing is a broad road leading south to the fountain, and north of the lake. On one side are Dahlias, edged with a broad band of Tropaeolum elegans. After crossing an open piece of lawn, on the right are rows of Dahlias, then Scarlet Geraniums, edged with yellow Calceolarias; and on the left are Dahlias, then Commander-in-Chief Geranium, edged with crimson-brown Calceolarias. Continue on the main road, leaving the fountain on your right, beside the walk diverging to the left; on one side is an edging of *Lobelia speciosa*, then *Calceolaria Aurea floribunda*, then Punch Geranium, backed by a broad and full band of *Chrysanthemum frutescens album*. On the other side is an edging of *Koniga maritima variegata*, then brown Calceolarias, then Nosegay Geranium, backed by double white Feverfew, which is not sufficiently high for the position in which it is placed.

Across the road to the fountain, and a few steps more take you to the north side of the lake. The outline of the lake is varied by the contrasted position of bays, inlets, and smaller indentations with islands, and acts to heighten the diversity

of appearance without destroying breadth of effect. An engine-house is visible in the distance, which supplies the lake with fresh water. We are told that on proceeding eastward and south of the lake the Rose-ground and other interesting scenes of floral beauty present themselves.

From the fountain a long broad walk runs westward, planted with a row of young Elm trees at each side. Turning from the end of the broad walk to the right we pass northward to a most interesting scene. On the south of Biocchi's refreshment-tent are two crescent-shaped beds. At the back, near the shrubs, are Hollyhocks, then Phloxes of various colours, then *Chrysanthemum frutescens* album, then Victor Emanuel Scarlet Geranium, then Minnie Geranium, then yellow Calceolaria, edged with Lady Plymouth and *Lobelia speciosa* alternately and diagonally. In front of each crescent are seven beds: the 1st, an oblong, with brown Calceolaria, edged with *Geranium peltatum* variegatum. 2nd, A circle, Anthony Lamotte Geranium, edged with *Lobelia Paxtoniana*. 3rd, An oblong, Stella Geranium, edged with Little David Geranium. 4th, A circle, filled with Calceolaria Canariensis, a splendid bed. 5th, An oblong, Miss Nightingale Heliotrope, edged with Bijou Geranium. 6th, A circle, *Centaurea candidissima*, edged with *Lobelia Paxtoniana*. 7th, An oblong, Stella Geranium, edged with Anthony Lamotte Geranium. The opposite is a duplicate of the above, with the exception of a circle centered with Madame Vaucher, a variety with large trusses of well-formed pure white blossoms. Going round from each end of the terrace, at the back are Dahlias; then Gaines's yellow Calceolaria, edged with *Nierembergia gracilis*. Then, proceeding westward on the broad walk, the next scene is an opening into the Park between high mounds picturesquely disposed, but the effect is marred by two beds planted with Hollyhocks. A few yards further on a fine lawn opens up, displaying a varied landscape to the wooded hills beyond, with church-spires, villages, and the Crystal Palace glittering in the sun. The varied and serpentine plantations on the left beside the walk are in part edged with Gaines's yellow Calceolarias, Pentstemons, Catmint (*Nepeta amethystina*), backed with Dahlias. The next bit of flower garden comprises an oblong with two circular beds; the first circle contains *Geranium Hendersoni*, edged with Cloth of Gold Geranium; the oblong, two rows of *Amaranthus melancholicus* ruber in the centre, then one row of *Centaurea candidissima*, edged with another row of *Amaranthus*; the other circle, Scarlet Geranium, edged with Bijou Geranium.

Still farther on the right are to be seen three large circles. The first contains Punch Geranium, edged with *Geranium peltatum* variegatum; the second, Crimson Unique Geranium, then a white *Pelargonium* like *Fairest of the Fair*, then Punch Geranium, then Pink Geranium, edged with Baron Hugel Geranium; the third, Trentham Rose Geranium, then Punch Geranium, edged with *Geranium peltatum* variegatum. On the left are several beds:—A circle filled with *Canna indica*, the fine foliage waving in the breeze; another circle of *Tritoma uvaria*, edged with *Nepeta amethystina*; an oblong, *Geranium Hendersoni*, then Christine Geranium, edged with Stella Geranium; two circles, Bijou Geranium, edged with *Lobelia speciosa*; another bed with a lot of *Geranium Hendersoni* in the centre, then Trentham Rose, then *Geranium peltatum* variegatum, edged with *Lobelia speciosa*; an oblong, Stella Geranium, then Commander-in-Chief Geranium, edged with Pink Geranium; two small circles, Madame Vaucher Geranium, edged with Little David Geranium. On the right are three circles; the first, Minnie Geranium, if I recollect rightly, edged with Trentham Rose Scarlet Geranium. A large circle filled with *Coleus Verschaffelti*—one of the most ornamental and picturesque-leaved plants yet introduced, amongst which it almost stands unrivalled for rich and gorgeous colouring—edged with *Centaurea candidissima*, is one of the most magnificent beds in the place: the secret of success here is having retained them in pots. The third is a circle of *Tritoma uvaria*, edged with Minnie Geranium.

We have now arrived at the lodge gate on the west side. A short turn and you are on a walk leading east by south through a shrubbery with a ribbon-border on each side, then across a portion of the lawn, and you enter what we were told is called the Italian garden. On turning to the right, the first bed which presents itself is filled with *Musa Caven-*

dishii, *Dracena purpurea*, and *D. terminalis*, and carpeted with *Aretotis repens* with its long silvery branches that literally stick to the ground. The bird's-eye view of the flowery vista beyond is most attractive. The next bed is an oblong filled with *Humea elegans* plunged in pots. Beds of *Canna indica* edged with *Statice* succeed. The Cannas are highly ornamental, producing a very rich and oriental effect by their large, broad, massive foliage terminated by racemes of crimson or scarlet variously-lobed flowers. The other beds consist of Variegated Periwinkle plants (*Vinca elegantissima*) and Yuccas. The circular beds opposite contain Vesta Geranium, edged with Minnie Geranium; Punch Geranium, edged with *Geranium peltatum* variegatum; Minnie Geranium, edged with Baron Hugel Geranium. There are in addition beds of *Caladium giganteum* and *Ficus elastica*. A long serpentine bed gay with yellow Calceolarias and Geraniums; and beds of *Vinca rosea alba* and *V. rosea ocellata*. The Cloth of Gold Geranium is very conspicuous as an edging to some of the beds.

On the circuit as you approach a portion of the lake the large frosted foliage of the *Salvia argentea* as an edging is also a conspicuous object. Then come a circle of Vesta Geranium, edged with Mountain of Light Geranium; two oblongs with Bijou Geranium and edgings of *Lobelia speciosa*; then a circle of Golden Chain Geranium, edged with *Lobelia speciosa*; another circle of *Coleus Verschaffelti*, edged with *Centaurea candidissima*. A crescent-shaped bed on the higher ground in front of the shrubbery filled with *Wigandia caracasana* is singular for its very large foliage. An edging of *Parfugium grande* is also worthy of notice.

From what has been faintly described it may, perhaps, be inferred that the rare collection of plants bedded out at Battersea Park is not surpassed, if it is equalled, in any other park, pleasure grounds, or flower garden in the kingdom.

The broad space between the road and the river Thames from Chelsea New Bridge to near Battersea Bridge is partly marked out for improvements; and to judge from what has been done by Mr. Gibson, we may confidently expect that such a fine site will be converted into a magnificent landscape scene.

W. KEANE.

MASSING OF COLOURS AT LINTON PARK.

I AM tempted to add a few words to the praises given in your last Number to the splendid results of Mr. Robson's grouping single colours in masses.

It cannot have escaped the notice of those who have seen Rubens' masterpieces that that great master of colour produced the main tone and effect of his paintings by the very same course now taken by Mr. Robson—a judicious use of his deep blue and deep red. The same effect may be seen, arising from the juxtaposition of two, or at most three, brilliant colours without any attempt at shading, in the illuminations with which old missals, &c., are filled, produced by the busy idleness of those conical mediæval vertebrates, the monks. So that the grouping in question arises from the purest taste, as well as being productive of the most artistic results.—H.

DRYING EVERLASTING-FLOWERS— GLADIOLUS DISEASE, &c.

IN No. 124 of THE JOURNAL OF HORTICULTURE is an inquiry how to dry Everlasting-Flowers—apparently a very simple thing, but in fact not so. I have been in the habit of hanging *Xeranthemum* and *Acroclium* up by the flower-stalk, the flowers downwards; but find that in doing so the flower when dry is very apt to break off the stalk, being then very brittle. I now cut them off with a sharp knife just before the flowers expand, and then lay them flat on a shelf in the greenhouse, full in the light. This causes them to expand and dry with the flower in the proper position.

When they are wanted for use I procure some wheat straw, 4 or 5 inches long, as may be required, and insert the flower-stems in them, and then make bouquets in any fashion desirable.

I will add that to do this I collect in the fields and woods handsome Grasses just before they turn white or ripe; these intermixed a little tastily make very handsome ornaments

for chimneypieces, &c. I have some now under glass that look as fresh as when cut two years ago.

Rhodanthe maculata is best hung up by the stem, flower downwards.

I have seen in a window one of the *Campanulas*. It seems like a trailing plant, and covered with light blue stars, and is very pretty for a window. Can you inform me which of the *Campanulas* it is?

A few of my *Gladiolus* have failed as you described, but

think it proceeds from the dry hot weather, as the bulbs do not appear diseased. I may remark that it is only those that have been in the ground all the winter that are thus affected; those I potted and afterwards put out are not so. Can any of your correspondents give a few recipes for cheaply dyeing grasses—say green and crimson?

Is there any other Everlasting-Flower you could name requiring the same culture, &c., as *Xeranthemum*, *Acroclium*, and *Rhodanthe*?—T. H. C., *Walsall*.

FLOWER-GARDEN PLAN.

I AM recommended to make a garden (as by plan), described as "an embroidered garden with Box-edgings and

coloured gravel." I think it would suit the place it is intended for; but having had no experience of such gardens,

I should be glad if you would inform me whether they are kept in order without any very great amount of skill and labour.—NEW FOREST.

[We think your embroidered garden will look very well, and more especially so if you can look down upon it—that is, if the beds are from 15 to 30 inches below the ground surrounding it.

But for such a garden there are too many sharp points,

and though they look rather well with Box or stone edgings, they would be annoying on grass.

We should deceive you were we to say such a garden would be easily kept. The Box must be regularly and often clipped, and the clippings must chiefly be picked up by hand. We presume the centre is to be grass: if of a bright colour it would kill the other beds.]

VEGETABLE TERATOLOGY.

A VARIETY OF PAPAVER WITH ANTHERS TRANSFORMED TO CARPELS.

DE CANDOLLE, in his "Organographie Végétale," figured a head of Papaver around which two or three of the stamens had changed into capsules. Subsequently, in 1832, I presented to the Congress of Naturalists at Vienna a more complete specimen of a similar monstrosity, the greater number of the stamens being in this case transformed into capsules more or less large. During the summer of 1839 I learned, that at some miles from Breslau there was a whole field of Papavers metamorphosed in the manner indicated. I obtained a considerable quantity of them, in all degrees of transformation, each central capsule having round it from one to sixty small supplementary capsules, and, what is very important, ripe seeds existed, not only in the principal capsules, but also in many of the accessory ones. The following year (1850), I sowed a good number of these seeds, purposely selecting the contents of the large capsules round which were arranged the smallest ones; I sowed these seeds in two different places—viz., one packet in a compartment well exposed to the sun; the second in a small sheltered garden. The result proved clearly that the metamorphosis in question was induced by circumstances the most favourable to the luxuriant growth of this species—namely, good soil, full exposure to the sun, and the greatest possible space for each plant.

In the compartment first named, the foremost part alone was unshaded; the other part, forming a partial slope, was shaded from right to left by some small bushes. At this latter point, the seed which sprung up in abundance was not at all thinned, so that the plants, more crowded, could not attain the same height as those of the other portion, where there was more space for their development. Nevertheless, of eighty of the first plants (of the portion not shaded), ten only did not present any trace of metamorphosis; all the others showed it in the most varied manner, though certainly it only attained its maximum of energy in ten cases. In the portion of the ground much shaded, where the second lot of seeds had sprung up, most of the heads showed metamorphosed stamens; but the number of these latter was, in general, very limited—one, two, ten, for each central capsule, and, among sixty of these capsules, two, at the most, had from forty to fifty small supplementary ones. Moreover, when even these small capsules were very numerous, and formed a circle round the central one, there remained a tolerable number of untransformed stamens on each head. Formerly I had supposed the metamorphosis to have absorbed all the male organs of the same flower; it was owing to my not having followed the phases of this transformation, my observations having been confined to the capsules which were already mature.

The metamorphosis begins ostensibly by the appearance of a substance which, produced with the torus, is interposed and developed between the bases of the filaments of the stamens, with which it effects a junction in the form of a ring. Subsequently this substance surrounds the principal capsule, either in part (in which case the metamorphosis only affects a small number of stamens), or entirely (when the most of the stamens are transformed). But in every case it is only the interior ranks of the stamens which become monstrous; the exterior ones preserving their normal form. As soon as the junction of the basis of the stamens attains the length of from 2 to 3 lines, the transformation of the anther to a carpel commences. At first the connective is swelled and becomes convex on the back, opening in a split in front. The exterior valves of the cells of the anther project, and become reflexed behind, in the form of wings. It is these which form the large and non-papillous border of the stigma. At the same time the external border of the partition of the anther becomes more prominent, and covered with papilla. It is this which forms the true stigmatic line which answers to the papillous rays of the stigmatiferous disk of the normal capsule. The analogy between the two is evident. The stigma is already formed when the ovules have not yet appeared. Their formation begins by the dilating of the connective: this organ opens more and more in front, and its cavity, which seems bordered by stigmatic papillae, soon shows the rudiments of the ovules. In proportion as this cavity becomes more profound (deeper) the upper part of the metamorphosed stamens takes the form of a hollow club, in which are developed by degrees the longitudinal ranks of the ovules.

Here my observations close. When the number of monstrous stamens is considerable, and, consequently, close on one another, they frequently split in two, three, four, together from the base to the summit, forming thus small capsules, with two, three, or four stigmatic rays, which come much nearer the normal capsule. It often happens, also, that ordinary stamens are joined to those which are metamorphosed. The above experiments are susceptible of being repeated with new modifications, and the subject, so far from being exhausted, promises interesting discoveries in science. A fact well established, is that the monstrosity in question is perpetuated from seeds during two generations, and ought, perhaps, to receive as a distinctive title, the name of *Papaver officinale*, var. *monstrosum*. The preservation of a plant so singular and interesting is worthy of all the care of horticulturists.—PROFESSOR GÖPPERT.—(*Flore de Serres*.)

HARDY AQUATICS.

WILL you state the names of a few water plants capable of bearing the full light and heat of the sun? In the grounds of a house to which I am moving, the lawn is separated from a field by a long piece of ornamental water,

the greater part of it entirely without shade. The late residents have for years kept swans on it; the consequence of which is, that the water and its banks are as completely unclothed as if it were a mere tank. My gardener says

Ferns will not bear the heat of the sun on the higher part of the banks, and that they would object to their roots being under water during the winter and rainy season, as the water is then much higher.—L. R.

[Instead of being troubled we should be delighted with the piece of ornamental water. We would clothe it with Willows and Alders. Of Willows, common Weeping, American and Kilmarnock ditto, and Silver-striped, Alders, Cut-leaved, Heart-leaved, and Hoary-leaved, which, with some shrubs, as Dogwood, &c., would very soon clothe it. The Giant Cow Parsnip is a very effective plant for the margin of pools, and once planted takes care of itself. For the water, if it be large, the following may be planted in the deepest parts:—*Nuphar lutea*, *Iris pseud-acorus*, *Typha latifolia*, *Alisma plantago*, *Villarsia nymphoides*, *Nymphaea alba*, *Alisma lanceolata*, and *Rumex hydrolapathum*. For the margin, or a few feet within the water:—*Caltha palustris*, *C. palustris flore-pleno*, *C. parnassifolia*, *natans*, and *minor*; *Butomus umbellatus*; *Calla palustris*; *Alisma ranunculoides*, *natans*, *repens*, *trivialis*, and *parviflora*; *Cardamine pratensis*, *C. pratensis flore pleno*, *C. amara latifolia*, *granulosa*, *prorepens*, and *dentata*; *Typha angustifolia*, *minima*, and *minor*; *Thalia dealbata*; *Swertia perennis*; *Ranunculus tripartitus*, *obtusiflorus*, and *aquatilis*; *Nuphar pumila* and *advena*; *Nymphaea odorata*, *pygmaea*, *nitida*, and *minor*; *Carex paniculata*; *Degeneria arundinacea*; *Glyceria fluitans*; *Catabrosa aquatica*, and *C. viridula*; *Phragmites communis*; *Hydrochloa aquatica* (an annual); *Alopecurus geniculatus*. *Hottonia palustris* and *Richardia athiopica* require protection in winter unless planted a foot or more below the surface. There are several more, but these strike us at the moment. The Pampas Grass grows well in wet places, and would no doubt luxuriate on the margin of water. We do not know the name of any person that sells aquatics, which is much to be regretted, as there are thousands of ponds and lakes quite barren, chiefly because people do not know of anything to plant in them, and if they do, nobody can tell them where they are sold. Any enterprising nurseryman might open up a good trade with aquatics. We will publish a few notes on their cultivation.]

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—AUGUST 25, 1863.

FLORAL COMMITTEE.—Rev. J. Dix in the chair. Seedling Dahlias formed the principal feature of this Meeting, and many very good flowers were exhibited; but the standard of perfection is now raised so high, and so many excellent varieties are in cultivation, that it requires something very superior to enable a seedling of the present day to merit a high award.

Mr. Keynes, of Salisbury, entered sixteen seedlings of the present year, all of them of considerable merit, or Mr. Keynes' name would not have been attached to them:—*Fanny Purchase*, a beautifully-formed, medium-sized, bright yellow, very first-rate in quality—first-class certificate; *Surety*, a dark-shaded buff, the backs of the petals tinged with rosy-red or cinnamon, perhaps a little too coarse a flower—second-class certificate; *Anna Keynes*, a very fine and delicate flower, white ground, petals tipped with pale lilac—second-class certificate; *Earl of Pembroke*, a magnificent and showy flower, deep claret, in form resembling and equalling *Lord Derby*—first-class certificate; *Regularity*, white ground, spotted and striped with maroon or purple—second-class certificate.

Mr. Legge, Edmonton, exhibited *Crimson Perfection*, a fine promising flower—commended; *Formidable*, a Fancy variety, white ground tipped with rosy crimson—second-class certificate; *The Bride*, a very pretty flower, good form, creamy white ground, shaded with purple—second-class certificate; *Nonsuch*, tawny or deep orange buff, good form—commended.

Mr. Wheeler, Warminster, exhibited *Symmetry*, fine dark crimson maroon—commended; *Cornet*, a dark claret with a lively bright glow on the surface of the petals, a very promising and useful medium flower—second-class certificate.

In Hollyhocks, the Rev. E. Hawke exhibited a fine spike

of his seedling *Willingham Defiance*, bright pink, full circular flowers, a very nice flower—second-class certificate. Mr. Bird Porter, Volunteer, dark ruby, very fine and full flowers; a spike of this plant would have probably gained for it a higher award—second-class certificate. Messrs. Downie, Laird, & Laing, Queen, creamy white, fine full flower—second-class certificate. Mr. Chater, Acme, a pale delicate bright rose of excellent form and distinct—first-class certificate. Mr. Chater sent also a collection of twenty-four fine flowers.

Messrs. Veitch, Chelsea, exhibited *Lilium Neilgherienne*, a beautifully-formed cream-coloured flower, resembling *Brownii* and *longiflorum*—second-class certificate; also two plants of *Lilium lancifolium album*. These Lilies were purchased at Mr. Stevens' sale in February last in a collection of Japanese bulbs.

Messrs. E. G. Henderson exhibited eighteen plants of a new bedding *Pelargonium Mrs. Benyon*, of dwarf habit, fine scarlet trusses, foliage very similar and quite equal to *Mrs. Pollock*—first-class certificate; *Pelargonium Rosette*, white variegated foliage, with pale rose flowers. Also a collection of twelve seedling variegated-foliaged *Pelargoniums* of great interest. Nos. 82, 53, 44, 5, appeared to be promising kinds.

Mr. Bull, Chelsea, exhibited *Vallota purpurea eximia*, exquisite in the form of its compact head of circular flowers, rather lighter in colour than *V. purpurea*; and although not a new variety, a scarce one—first-class certificate.

Mr. G. Smith, Hornsey Road, brought cut blooms of his superb *Scarlet Pelargonium Lord of the Isles*, which was awarded a first-class Certificate at Chiswick on the 11th ult. It was much admired by those who had not seen it before.

Mr. Amey sent a seedling *Ageratum* of no particular merit, little differing from the one in general cultivation.

Mr. Melville, Dalmeny Park, sent cut flowers of *Calendula officinalis*, but they were too much injured to be examined.

Mr. Backhouse, York, sent *Cyrtanthus (Gastronema) sanguineus*, a very pretty amaryllidaceous plant of various shades of rose and pink, said to be as hardy as *Gladiolus gandavensis*. Should this prove to be the case it will be a very useful and ornamental plant—first-class certificate.

Mr. Bateman exhibited a very fine plant of *Epidendrum vitellinum* with four spikes of flowers. Although not equal to *Epidendrum vitellinum major*, it was a specimen of good cultivation, and a special certificate was awarded. Mr. Bateman sent with this Orchid a very interesting paper, which was read before the Committee, on the cultivation of this interesting family; and although it contained no information which had not been previously given on the subject, it will certainly afford a fresh impetus and give encouragement to the admirers of Orchids. Mr. Bateman particularly directs the attention of all cultivators of Orchids to considering the different climates from which they receive them. He has found as well as others (J. Day, Esq., and Messrs. Veitch), that many kinds which have been injudiciously treated by being grown in a house of an unnatural temperature to them, have perished or imperfectly developed themselves; hence the necessity of attending to the climate of the country of which they are natives. It will be found that an ordinary greenhouse is all the protection that many of these lovely flowers require. Indeed, *Lycaste Skinneri* has kindly accommodated itself to the temperature of a lady's drawing-room, where it has not only reproduced its flowers, but formed fresh bulbs.

Plants of *Scarlet Pelargoniums Waltham Pet* and *Mrs. Cowper* were brought for comparison, but this object was defeated, the plants of each kind not being of the same age and not grown under the same circumstances; the majority of the Committee, however, were inclined to prefer *Waltham Pet*. These dwarf *Scarlet Pelargoniums* will be found most useful for decorative purposes, especially for baskets and vases.

FRUIT COMMITTEE.—Mr. H. J. Veitch in the chair. A seedling *Black Grape* was received from Mr. John Matheson, gardener, Coddington, near Winslow, which bore considerable resemblance to the *Black Hamburgh*; but still distinct, both in texture of the flesh and in flavour. Having been grown in a pot the fruit was evidently not sufficiently developed, and the Committee recommended that Mr. Matheson

plant the Vine out, and give it a good chance of showing its true characteristics. It may prove a good thing.

Mr. Wm. Melville sent two fine bunches of his new Grape Muscat Champion, which has been before the Committee two or three times before; but on this occasion the bunches exhibited far outdid those previously shown. The berries were as large as those of Mill Hill Hamburgh, and the bunches were short, wide-shouldered, and like a bunch of grape shot. The flavour was delicious, and had just enough of the Muscat flavour to be satisfying. The colour, however, still remains brownish-red, but we are of opinion that by management it may become as black as a Black Hamburgh.

Mr. Gayland Hadwen, of Fairfield, Manchester, sent a bunch of Grapes under the name of Muscat Lunel, which was not that variety, but evidently what is called the White Tokay or White Nice.

Mr. Andrew Dick, of Sudbury Hall Gardens, near Derby, sent two sorts to be named, one of which was the old Black Prince, and the other a variety that could not be identified.

Mr. Edward Pierce, nurseryman, Yeovil, sent a dish of a seedling called the Cricket Peach. The fruit has the dark appearance of *Violette Hâtive*, and is of large size; but it is very different from that variety, and has large flowers instead of small ones as the *Violette Hâtive* has. The flavour was very rich and excellent; but the great recommendation of the variety is its hardiness, Mr. Pierce having stated that for the last two years, while all the other Peach-buds in his nursery have been killed by frost, these remained uninjured.

A Peach was sent by Mr. C. Griffith, gardener to A. F. Paxton, Esq., Cholderton House, near Salisbury, which proved to be Yellow Admirable.

Mr. Edward Cooling, nurseryman, of Mile Ash, near Derby, sent a Scarlet-fleshed seedling Melon, which was of oval shape, ribbed, and netted. The flesh was tender and melting for a Scarlet-fleshed Melon, and of tolerably good flavour, but not sufficiently rich to recommend it as a new and desirable variety.

A seedling Apple sent by John Gidley, Esq., Bedford Circus, Exeter, was raised from Cornish Giliflowers. It was a nice-looking Apple not unlike the Early Harvest in appearance, but far inferior to it in flavour. It was not considered to possess sufficient merit.

Mr. Chater, of Saffron Walden, sent specimens of a seedling Apple called Elizabeth Pine that were gathered in October, 1862: they, of course, were much shrivelled, and the flavour was gone. It is a pity Mr. Chater did not exhibit them two months ago.

WORK FOR THE WEEK.

KITCHEN GARDEN.

A GREAT change has taken place in the weather since last week. Frequent showers have greatly refreshed vegetation. Now is the time to be busy with the hoe in earthing-up the various crops that require it, and also for planting-out those that, from the dry state of the weather, could not be put out before. *Broccoli*, where there has not been sufficient planted, large plants may yet be put out with success. They should be laid-in with a spade in a slanting direction. Earth-up the advancing crops. *Cardoons*, earth-up for blanching in favourable weather. *Celery*, proceed with the earthing-up in proportion to the demand. Some of the very latest crop may also be planted in rows to stand through the winter. The haulm of Peas laid by now in a dry place is a good material for covering *Celery* during severe frost. *Cabbage*, the seedling plants intended to stand through the winter to be pricked out in nursery-beds of light soil at 5 inches apart. This will be found of great advantage by inducing a stocky hardy growth. *Endive*, continue to make successional plantations. Some of the first-planted-out will now be in good condition for tying-up for blanching. A few only at a time to be done, and these tied loosely to allow the heads to swell out large. *Lettuce*, a small patch of Bath Cos sown now will, if the autumn prove mild, be more valuable than those sown earlier. *Mushrooms*, beds may now be made either in sheds or in the open air. *Onions*, no time should be lost in getting the crops

stored when fully dry, as the ground from which they are taken is generally used for Cabbage. It should be immediately trenched-up. If manure is necessary, let it be laid on the top of the trenched soil and fork it in. If, however, the ground was well manured for the Onions, it ought to carry the Cabbage through, and that will always come the better, because, if too much manure comes in contact with the roots in the autumn, it induces a succulent luxuriant growth, which renders them very liable to injury from alternations of frost and thaw in the winter. *Parsley*, thin the summer sowing while in a young state, the plants will then gain strength to stand the winter. A portion of the spring sowing to be cut down. *Tomatoes*, gather the fruit as it ripens, remove all the shoots that shade it, also some of the leaves.

FLOWER GARDEN.

Unless some precautions are taken to keep the taller plants in the beds of geometric flower gardens within proper limits, they will be likely in a short time to grow too high, and will disturb the uniform appearance essential to this style of gardening. A constant watch should, therefore, be kept on plants likely to exceed the standard height, and by frequently pinching back or pegging down endeavour to keep the same-pattern beds at an equal height. At this season, with beds of flowering plants, frequent cutting-back and trimming will be required to prevent straggling in free-growing plants, and this the late rains will encourage. At the same time, allow no dead flowers or seed-pods to remain on the plants. By careful attention to these little matters the season of blooming may be prolonged till the plants are destroyed by frost. Although the present month is a favourable time for transplanting evergreen trees and shrubs, it generally happens that a large amount of this kind of work is put off until so late that the plants have no time for pushing a few fresh roots to enable them to resist the cold drying winds of March. It will also be found that plants lifted during this month will require but little attention in the way of watering next spring and summer compared with others transplanted in winter and spring. The removal of deciduous trees and shrubs to be postponed until they have shed their leaves.

FRUIT GARDEN.

The gathering and preservation of fruit is the principal work here. Peaches and Nectarines should not be allowed to remain on the tree until what is technically called dead ripe. A little degree of practice will enable a person to determine the degree of ripeness at which it should be gathered without resorting to the common and barbarous way of pinching. Plums should be allowed to remain until perfectly ripe; and although something may be lost in bulk by being allowed to remain on the tree, the flavour will not be deteriorated. Such as the *Impératrice* and *Golden Drop*, if protected from wasps, may be kept until a very late period in the season. Apples and Pears generally fall as soon as they arrive at an early degree of ripeness. That period must be anticipated, and their removal effected as soon as it is ascertained. After gathering, the fruit intended for keeping should be laid out in the fruit-room for a week or ten days, and exposed to a free circulation of air. The fruit will be found clammy from perspiration. It should then be carefully wiped and laid out thinly in the store-room, which should be kept, as soon as the fruit is introduced, securely closed and protected from any very material alternations of temperature.

GREENHOUSE AND CONSERVATORY.

Climbers will always require attention to keep the shoots in their proper places. Take care in training that the part of the trellis or stakes near the bottom is not bare of flowering shoots, as the beauty of the plants depends upon their being clothed with foliage and flowers from the rim of the pot upwards. The potting of *Hyalcinths*, *Narcissi*, *Tulips*, &c., for forcing must soon occupy attention. About equal portions of loam and leaf mould, with a sprinkling of sand, will be suitable soil for them. After potting, place them on a dry bottom, and cover the pots 2 or 3 inches deep with ashes, preserving them at the same time, as much as possible, from heavy rains. Under this treatment they will fill their pots with roots, and will be in readiness for forcing when wanted. Most of the class of bulbs known as Cape bulbs, if obtained now, might, by the aid of a little extra

heat, be had in flower at various periods throughout the winter and early spring. Any of the free-growing species of *Ixia*, such as *flexuosa*, *viridiflora*, *conica*, &c., would be suitable, as also would be the varieties of *Sparaxis tricolor*, and *Amaryllis vittata Johnsoni*, which are splendid, and may be bloomed by gentle forcing. *Lachenalia pendula* and *tricolor*, with many species of *Oxalis*, would serve to increase the variety, and are all handsome. *Ornithogalum amicum* is a fine orange-flowered species. *Cyclamen coum*, *vernum*, and *persicum* ought not to be omitted.

PITS AND FRAMES.

Let scarlet and other *Geraniums* struck in the open ground be taken up and potted immediately they have made roots. They will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure to harden them for the winter. For the same purpose *Verbenas*, *Petunias*, &c., struck in pans, and intended to be kept in them through the winter, should be placed in a similar situation, at the same time stopping the points of the shoots. The principal object should be to keep them as hardy as possible by fully exposing them until they are placed in their winter quarters. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE glorious rains have come at last, and refreshed the thirsty earth, and cheered up the countenance of many a resident in cottage homes. It will also be a great boon to the farmer; delaying his carrying, it is true, but making his Wheat tell better in the bushel, and scattering insects and mildew from his fields of Turnips. For ourselves, we only had a few gallons of clear water left, and many things out of doors were fading and shrivelling without the chance in our power of greatly benefiting them. Now we may expect Peas, and Beans, and Lettuces, and Turnips, to be all right again—at least it will be some time before we can plead the excuse of dryness again, if anything should not be right or not be obtainable at all. After the first shower, feeling confident that more was coming, we gave a good soaking to Cauliflowers, Peas, Celery, &c., with sewage water, which would have been rather strong without the rains that were to follow. There can be no mistake as to the usefulness of much of the water that runs to waste from a gentleman's house. All the soap, greasy water, &c., that thus is often lost is most valuable when rightly applied and at the right time; and that time we hold to be when vegetables are growing freely. In hot summers nothing can be more suitable for Asparagus, Sea-kale, and all the rougher vegetables, only it must not be given too strong. "But why apply any at all when you saw that rain was coming?" A gentleman told us the other day, half derisively—"Why, F—, I am sure it will be rain, since you are watering." Well, the truth is we did not expect so much rain as we have had; and, again, we valued the sewage for root-watering even more than the rain; and, again, we find that all waterings are most effective that are given just before a good shower, or during the dull weather that generally precedes and follows a fair amount of downpouring. When plants in the ground, be they residents of the kitchen or the flower garden, are evidently suffering from want of water, it is right and proper to water them at any time; but the effects are very different when water is given in the forenoon of a sunny day, and in the afternoon when the atmosphere is quiet and clouded. In the one case, the moisture is evaporated almost as soon as given; in the other it is absorbed by and has time to pass through the whole of the plant. A summer shower very often merely refreshes the foliage and gives nothing to the root-absorbents. It is a capital thing that sunny shower after a hot day: it refreshes and invigorates; but the moisture is soon dispelled, and the roots are as dry if not drier than before, on account of the temporary obstruction to the moist vapour rising from beneath. We know it is good for tender invalids to be placed in a medicinal bath, and thus to be fed through the pores of the skin; but we would have greater faith in a perfect recovery to health could the patient at the same time masticate some of the "roast beef of old England." Instead of being sneered or laughed at, then, the

man who waters the roots of a plant before a shower or in dull hazy weather, provided the plant wants it, is just exercising all the good common sense of practical philosophy.

Whilst on the subject of watering, allow us to say that the time of doing so is even more important in the case of flower gardens; hence, where practicable, as a general rule, from June to September it is best to water in the afternoon and evening. We have watered often in the morning, merely because we could manage to obtain water then and at no other time. In hot weather, however, we liked to keep it in the ground either by covering or loose-stirring the surface. But the chief reason for watering dry flower-beds before a shower is simply this: that if the roots are at all active, a heavy shower will fall on a gorgeous parterre and leave it in a few hours still more splendid; but if the roots are excessively dry, and the plants and flowers in a suffering state, there is every chance that the flowers will be knocked off and the beauty of the group be departed until fresh flowers are formed. The man who gives a little water at the roots, therefore, in such circumstances, when he sees something like a deluge coming, or even a good shower, is not so deficient in thought after all.

Put out more greens. The rains just suited seedling Lettuces, Cauliflowers, Turnips, &c., and were just suitable for planting out lots of Endives, Lettuces, &c., which it was no use attempting before. Gave the final cartling-up to some Celery. Scarlet Runners that had a good drenching are now all right and as crisp as possible. In the dryness the flowers refused to set, and the same as respects late Peas. Put out a few Leeks, as large ones are not desired; but to our taste they should be white as milk, as thick as our wrist, and then, well boiled and used with a little butter, pepper and salt, even an epicure might smack his lips over them. The rains have also helped to clear-off lots of caterpillars from Turnips and Greens; and we should have been much worse but for the thousands of butterflies that were struck down by the boys. Now also the Tomtits and other birds that annoy us not a little in the spring are doing good service. It is amusing to see the little fellows examine a trench from end to end. As soon as the ground is dryish on the surface will run the hoe through all openings to cut down the incipient weeds and keep moisture in the ground.

FRUIT GARDEN.

Kept thinning the fruit of dwarf Pear trees, and find that the pig is very fond of them, even in the hard state. Owing to the dryness everything in the shape of Greens, Lettuce stalks, Cauliflower stalks, &c., has been more than ordinarily agreeable to the pig. Went over the trees, finally shortening, disbudding, and thinning fruit where too numerous. The rains will help the fruit now as to swelling, and plenty of sun will be sure then to give flavour. The rains gave also just what was needed for Vine and Peach-house borders. In the case of the latter, where the fruit is wished to stand all the winter, the borders should be protected from heavy rains by the middle of next month. In the case of the early vinery where the wood is ripe it would be well to prune and remove the lights for a time. We think it a good plan for settling all insects. The same may be done to early Peach-houses, though they do well enough with roofs that cannot be removed. Still if they were well drenched with the rains of October, and had a little of the frost of November before being shut-up, a good many insects are likely to be punished. Without this help there must be more care in washing and cleaning. Thinned-out Currant shoots, as we needed them in the flower garden for our patent pegs, and will thin Raspberry shoots as we can find time. Clipped the Box-edgings in the kitchen and fruit gardens, not because it is the very best time, but because done now they will look well for a twelvemonth, whereas if done early in the season it would have required to be done twice. When strong and long established we have done it first-rate with the scythe, with or without a line down the middle; but our present edgings are better clipped with the shears. Vineries, Melon-pits, &c., much the same as preceding weeks.

ORNAMENTAL DEPARTMENT.

Changed plants in, and freshened-up the conservatory. Cut down a lot of Pelargoniums. Shifted many plants that they may be rooted before winter; but the great work has

been propagating for the flower garden, and, after other things, going on with Variegated Geraniums, placing them thickly in portable boxes to avoid moving them until spring. These cuttings are about an inch long and will be placed in an airy place under glass. We will follow with the common Scarlets, and will merely take a batch of each kind and come over them again, as we do not wish to injure the outline of the beds for two months to come. These boxes average 3 feet in length, 9 inches wide, and 3½ inches deep, made of any boards we can lay our hands on. The boards are not planed, but are whitened, and the openings give sufficient drainage. About an inch of rough stuff goes over the bottom, then fresh sandy soil, and a sprinkling of sand on the surface. We must not speak of the future; but we shall be vexed if one per cent. of the cuttings made should bid us good-bye. After the trouble of putting them in, it is very annoying to see, first one, and then another, go off. Care must be taken to prevent this. A gardener told us the other day that he was once advised to carry home his cuttings, throw them out in the sun for a day, and then make and plant them. This may do with Scarlet Geraniums, though even with them we see little advantage in ever allowing them to shrivel; at least, it would not do any good with such little bits as we use. With respect to most plants the advice was equivalent to telling a man to take the cuttings home carefully, and then throw them on the rubbish-heap.—R. F.

TRADE CATALOGUES RECEIVED.

R. Parker, Exotic Nursery, Tooting.—*Catalogue of Stove, Greenhouse, and Hardy Plants, Hyacinths, and Bulbous Roots, &c.* 1863.

Charles Turner, Slough.—*Catalogue of Bulbous Flower Roots and Tulips, &c.* 1863-64.

COVENT GARDEN MARKET.—August 29.

The market continues very well stocked both with fruit and vegetables. Wall-fruit in particular is coming in in very great abundance. The supply of Grapes and Pine Apples is quite sufficient for the demand. Melons are plentiful. Filberts are bringing rather better prices in consequence of the supply falling off. Potatoes are still heavy. Flowers chiefly consist of Orchids, Pelargoniums, Verbenas, Asters, Calceolarias, and Mignonette.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

USE OF MOSS FOR DRAINAGE (B. F. M.).—Moss is probably not necessary to be placed over the potherds in the course of potting plants. Anything will do for the purpose that will prevent the fine soil filling-up all the interstices between the crocks. Much depends upon what plants are being potted, whether the plant has to remain in the same pot a short time or a long time. If a long time we like a little moss; if a short time and growing quickly, as in potting-off Balsams in spring, or young Cucumbers, &c., it is no matter what is used. We cannot tell the name of the enclosed Fern. It is a seedling from some of the *Lastrea* family.

TREMANDRA VERTICILLATA CULTURE (E. W.).—It is described in most botanical and horticultural works as *Tetratheca verticillata*. It was discovered by Mr. Drummond at the Swan River, and was first flowered in this country by Messrs. Low, of the Clapton Nursery, in 1846. It is a charming greenhouse plant and easily grown. It requires plenty of root-room, and a soil composed of equal parts sandy fibrous loam and leaf mould well drained. It is propagated by cuttings of the young side shoots in sand under a bell-glass, air being admitted constantly to prevent damping. Be careful not to give too much water, or to pour it over the leaves.

VINES IN BOXES (Nottingham).—If we had a choice we should prefer boxes to pots, but Vines may be grown equally well in either. Rich turfy loam three parts, and one part thoroughly-decayed stable-manure will form a good compost. The Purple Constanza is as easy to cultivate in a warm vinery as any other variety.

PROPAGATION BY BEGONIA LEAVES (T. E.).—It is well known that Begonia leaves will emit roots and form plants; therefore it is not surprising that young plants have arisen from the bases of the leaves of your specimens of *Begonia Rex*, *Victoria*, and *Marshalli*.

LONGICERA FRAGRANTISSIMA NOT FLOWERING (E. B.).—We can only account for your plant not flowering by supposing it to be on the shady side of a wall or to be shaded by some other object, or perhaps its roots were too wet to enable it to ripen its wood well enough the preceding autumn. Try a plant in a dry sunny place, and we expect it will flower if the other conditions be right.

COTONEASTER NUMMULARIA NOT FLOWERING (Idem).—The flowers of the Cotoneaster are so slightly ornamental to the plant that few would regret its not flowering, excepting for the fruit that follows. Perhaps your plant is in a shady or damp situation, both of which positions are inimical to the plant flowering well. Remove it to a dry sunny bank, and the probability is you will be rewarded by abundance of bloom.

WHITE LILIES AND PHLOXES NOT PROSPERING (M. F.).—It is seldom these two plants are both found good at the same place; the one liking a dry soil, the other requiring a deeper one and much more moisture. The Lilies in a damp place suffer from slugs; and we suspect they have injured the flowering bulbs, otherwise we have often enough seen patches of Lilium that have not been disturbed for many years, and yet continue to flower well. Plants of many of the herbaceous Phloxes are often ill-used in winter by having all the outside portions of the plant trimmed off, so as to make it, as the operator says, tidy-looking. Unfortunately, in so doing the best part of the plant is cut away, leaving only the centre or core, which flowers but indifferently. It is better practice, in the autumn or winter when the borders are dressed, to cut away all one side and as much of the middle as can be done, leaving the nice young portion of the other side, which flowers vigorously. The same remark holds good with Campanula and other things. Generally speaking, the Phlox likes a damp season rather than a wet situation; while on a dry place it suffers severely, the plant showing all the appearance of a potted plant languishing for want of water. Cuttings of Phlox taken from side shoots, and cut into lengths of two or three joints each, root freely in any sandy soil, but they ought to be taken off early and before the shoots have attained two-thirds of their growth.

BRUGMANIA ARBOREA FLOWERING DWARF (M. T.).—It is very seldom this species is met with flowering at the height you mention, neither do we think the mere fact of raising plants from the ripened wood of a former year will insure this object, as the flowers all proceed from the wood of the current season, and not, like those of Hydrangeas and some other plants, from the ripened and prepared bud of a preceding autumn. A free growth and full exposure to sunshine will in a general way insure flowers on plants under glass; and those planted outside will also flower well towards the end of a hot sunny summer, but they will not always do so in dull seasons or situations deficient of sunshine. We do not see any advantage in a pendulous-flowering plant like the *Brugmania* blooming in so dwarf a condition, as the flowers will be too low to be examined or looked at with comfort.

APPLYING GUANO AND SUPERPHOSPHATE OF LIME TO GROWING CROPS (F. B. L.).—For hard-cropped garden ground half a ton per acre may be given of each during the year; but it ought to be given at three or four times—say 3 cwt. at the time of digging, and the remainder by surface-spraying during the summer. Most likely a second crop will be wanted, and of course an additional dressing will be wanted there again, but half a ton per acre per annum will be sufficient. Amongst the crops in summer these manures are best applied just prior to rain.

LATEST TIME AT WHICH IT IS SAFE TO PLANT STRAWBERRIES (Idem).—By taking off the runners in good time and planting them out on good ground, they may be taken up in October with good-sized hills and planted out in their final quarters; and if severe weather follow quickly on their planting-out, let some rough pea-haulm or dry straw be spread over them to prevent the frost from heaving them out of the ground. By taking them up with large balls we have removed them successfully at various times during the winter.

TWELVE GOOD VERBENAS (Sheffield).—Lord Raglan, Nemesis, Desdemona, Lord Leigh, Lord Craven, L'Avenir de Bellait, Gant des Batailles, Chiel-tan, Ruby, Admiral Milford, Faust, and Fareast of the Fair.

EARLY-RIPENING MUSCAT GRAPES (G. H.).—A detailed answer to your note will be in next Tuesday's Journal.

PRESERVING LATE GRAPES (G. N.).—The best treatment you can adopt with the Vines the Grapes of which are now colouring, and which you wish to preserve through the winter, is to give them a little extra heat with air on, so as to have them ripe in September. They will hang better afterwards. Then keep excessive wet from the roots, as well as cold or frost. Keep the house any day and night, and in dull cold weather put on gentle fires to enable you to do so, giving most fire during the day, and more especially if the weather is at all dull and foggy. In a very foggy day give little air. Be sure you keep out frost—very little will injure the grapes and cause them to rot. Even without that it injures the flavour. Keep the floor, walls, &c., as dry as possible after the end of August. We think your early Grapes have kept very fairly. Very probably the shrivelling may be owing to excessive heat and dryness. Very likely if in these hot sunny days you had just damped the floors and paths a little, the Grapes would have been more plump. As it is, the moisture has been evaporated, and you have something like a first-rate Raisin—no bad thing in its way. In such hot weather we lessen air during the day, to prevent such excessive drying.

LIST OF AGRICULTURAL SHOWS (A Year's Subscriber).—In Mr. Cuthbert Johnson's "Farmer's Almanack" is a list of all the Societies and their Secretaries.

SIX HYACINTHS FOR EXHIBITION (A Novice).—Dark red, Robert Steiger; light ditto, 1 a Dame du Lac; dark blue, Prince Albert; light ditto, Grande Vidette; white, Grandeur à Merveille; yellow, Soleil d'Or.

CUTTING-DOWN CYANOPHYLLUM MAGNIFICUM (C. S. N.).—You may cut down this noble plant if you want it to come away with two or three stems from near the surface of the soil; but, in order to induce it to break kindly, you will require to plunge it in a bottom heat of 80°. We would much rather allow a plant about 2 feet high to grow on than cut it down or stop it, as, according to our ideas of the beautiful in this plant, it never looks so well as when brought away with a single stem and allowed to branch right and left, which it will generally do when about 3½ feet in height. With a leader and a few lateral growths it is much more handsome than when brought away with more stems. The loss of the bottom leaves arises from some check. We have had them drop when the plant has been exposed to a current of dry cold air, and when it has been left too long without a shift, or has been neglected in the matter of watering. It is a plant which thrives amazingly if watered with guano water. We have two splendid plants of it just now which have been grown on from last autumn's cuttings, and they are now beginning to branch without any stopping or pinching. We always prefer rapidly-grown plants of one year's growth to larger plants. There is a freshness and vigour about them which is not generally found in older plants which have stood a long time in the same pot.

FUNGUS IN TAN-PIT (Dorsetshire).—The fungus in your tan can readily be removed by rubbing it sharply with the hand on its first appearance; but a better plan is to take the parts infected away, there being no necessity to burn it, as it is perfectly harmless, though unsightly. We use cocoanut fibre, but have not been troubled with any fungus, though we have had Ferns in great literally one mass of yellow froth or foam, which succumbed to a washing with water, care being taken to leave none of the yellow froth on the soil. By frequently rubbing and removing the froth—or, as botanists call it, "mycelium"—you need not fear any harm from this fungus; but if left to spread and remain until it becomes brown, the spores will fly about in all directions and vegetate whenever they find a substance in a state of decomposition to adhere to, accompanied by a close stagnant air.

PROPAGATING HARDY HEATHS (P. E.).—Hardy Heaths when young may be propagated by division, taking the parts away without shaking off any soil that may adhere to the roots. It should be done immediately after each species flowers. All Heaths are best propagated from cuttings, putting in the tips of the young shoots when the wood is about half ripe. The cuttings need not be more than from 1 to 3 inches in length. Put in as for any other description of cuttings in fine peat and silver sand in equal parts, scattering a little of the last between the cuttings; place in a cold frame, after which they must be gently watered and shut up quite close. Keep the sun off, but admit all the light possible, and give neither air nor water the next thirty days unless the soil is becoming dry, when it must be given even before it becomes dry. All that is required is to keep the soil moist, not wet, and the atmosphere close, but not stagnant. You may strike hardy Heaths under a bell-glass in a shady place, but free from drip; only put in cuttings of the half-ripened shoots. The plants themselves will tell you when this kind of work ought to be done, for Heaths flower at different periods, therefore we can't give any particular time for taking cuttings. Heaths detest the knife, though unsightly growths may be removed; yet if hardy Heaths have room, they seldom need any pruning. Paul's "Rose Garden" will suit you.

LIFTING VINE ROOTS (A Constant Subscriber).—We prefer lifting the roots of Vines early in March; but, if the Vines have been forced, we should prefer lifting the roots in the autumn immediately after the leaves fall off.

AMERICAN BLIGHT (Idem).—Take equal quantities of unslacked lime and soot, and form them into the consistency of thick paint by a sufficiency of urine, and apply this hot (180°) to the trunks of your trees with a scrubbing-brush, rubbing it into every crevice. Scrubbing the trunks alone will rid them of moss, and brushing ammoniacal liquor from the gas-works into the parts infected with blight will free the trees of it.

DANDELION ON A LAWN (Idem).—Any time and all times are suitable for destroying Dandelions on lawns. It is a good plan to go over the lawn periodically and take up all the Dandelions with a long-bladed knife, cutting them off as much below the surface as possible. Persist in this, but for one season remove them as fast as they reappear, and towards autumn in wet weather drop a little salt into each hole after removing the Dandelion, and you will rarely see any more of them the season following. But bear in mind, if Dandelions are allowed to seed anywhere near your lawn, it will never be free from them, for the wind scatters the seed far and near.

MUD FOR FRUIT TREES (Idem).—The leafy mud of your ditch, exposed to frost and mixed with unslacked lime, would not injure the soil of any garden; but as to its suiting your Peach trees we cannot say, as we do not know whether your soil is heavy or light. If it is strong or clayey it will suit Peaches; or, if it is light, the soil out of the ditch will do it good.

HOLLYHOCK CUTTINGS (A Constant Reader).—If you refer to page 91 of our present Volume (No. 123) you will find the directions you require.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (H. E.).—It is a shrub—*Rhus cotinus*, or Venetian Sumach. (A. Five-years Subscriber).—1, Not a *Spirea*, but *A. tilia rivularis*; 2, *Galega officinalis* alba, the white Galingale; 3, *Geranium striatum*, Streaked Crane's-bill; 4, *Achillea rosea* gardeners call it, but it is *asplenifolia* of books; 5, *Achillea eupat. rum*, the Cuspid Millot; 6, *Linaria pectorata*, the regular-flowered variety of *Linaria vulgaris*—a curious and very rare plant. (H. B.).—1, *Adiantum hispidulum*; 2, *Asplenium flaccidum* (2, too small a bit to be quite certain; 3, *Gymnogramma calomeanos*, sometimes called *G. peruviana*; 4, *Diosma ericoides*. (J. Bryan).—1, *Lastrea dilatata*; 2 and 3, *Polystichum*, forms of *aculeatum*; 4, *Lastrea oreopteris*; 5, *Lastrea Filix-mas*; 6, *Athyrium Filix-foemina*, var. *incisum*. (C. E.).—1, *Salvia horminum*, var. *violacea*, or the Purple-topped Clary; 2, *Scutella varia*, violet-coloured Catmint.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CRYSTAL PALACE POULTRY SHOW.

THERE have been many inquiries why there has been no Show at the Crystal Palace, and when there would be one. We have given no answer for the best of reasons—we could not. We are, however, happy to say we have authority to announce that one will take place in October, about the middle of the month, we believe to begin on the 19th. This will be instead of the two Shows, and will doubtless prove an unusually large and good one. Many who can hardly make up their minds to show their chickens in August will willingly do so in October; birds are then in hard and good condition. We think Mr. Houghton has shown a wise discretion in choosing the midway between the two. The Chicken Show in August was too early for most classes, except Game and Dorkings, and yet it was too late to hope for much company from London. It took place when London was positively empty. The Winter Show clashed with Birmingham, and it suffered in consequence. It also took place when the Palace was a carpenter's shop preparing for Christmas revels. Spite of all these drawbacks, and the fact that only those who, like Bombastes, are "stout of heart and limb" dare face the deplorable railway arrangements, yet the Shows have been a success throughout. May we not then fairly expect numerous entries from our best yards in October? Lovely autumn weather, daylight, and the Palace in a fit state to receive company will help, we hope, to make the Show a real holiday to amateurs and a profit to the shareholders. We think it deserves support as the London Show, and it has strong claims on exhibitors from the punctuality which has always been one of its chief characteristics in every particular.

THE ISLINGTON AGRICULTURAL HALL POULTRY SHOW.

THIS Show of poultry has proved itself one of the most successful ever yet held in the great metropolis. It was appointed exclusively for young poultry of the present year, and consequently, the prize list being a most liberal one, a competition ensued very rarely known so early in the season. To poultry amateurs such a meeting had especial interests, as foreboding the probable strength of the yards of most of our reputed breeders. As being chickens novelty was universal, and few, if any, of the company assembled left without the spontaneous expression of approbation so good a collection richly deserved.

It is almost useless to make any remark whatever as to the eligibility of the Islington Agricultural Hall for the purpose of a poultry show—certainly it is not surpassed by any we have yet visited. On this occasion all the poultry was exhibited in the extensive gallery that surrounds the whole building. They were ranged entirely in single tier; not a dark pen could be pointed out anywhere, and all were alike conveniently placed breast-high.

In *Spanish* Mr. Rodbard took his customary position with a splendid pen; but in cockerels Mr. Lane obtained the mastery.

In the class for *Grey Dorking* chickens Viscountess Holmesdale exhibited a collection of which any amateur would indeed be proud. It must be borne in mind, that as being

exclusively a chicken show, not any of these excellent fowls had been before exhibited. The result was that their fair proprietor secured the first prize for single cockerels, first prize for pair of pullets, and a similar prize for the best cockerel and two pullets, besides minor premiums; this latter pen also obtaining the Silver Cup for the best pen of fowls of any breed in the Show. They were a most promising pen of chickens, possessing a great amount of bone, well-conditioned and well grown, the plumage being of the dark hue so well known among Dorking-fanciers as "Captain Hornby's colour." They were some of the most remarkably close-feathered Dorkings that have ever been shown, and from their youth will no doubt improve considerably ere they cease growing. The Rev. G. F. Hodson's White Dorkings were such as are only met with at long intervals.

In the Buft *Cochins* Mr. Kelleway entered a pen of the most unquestionably good chickens that have been shown for years past. These birds, being bred in so favourable a climate as the Isle of Wight, obtained an advantage that may not hold good at the Christmas shows. Be that as it may, they proved the much-coveted ones at the Islington Meeting. Mr. Stretch's pen of Partridge-coloured Cochins were of scarcely less merit; and the same remark applies with equal force to Mr. Dawson's pen of White ones. It is a rare occurrence that Mr. Chase has to play second to any one in this last-named variety, but in this instance he was completely distanced.

In *Brahmas*, Mrs. Fergusson Blair exhibited such a lovely pen that they ran in very closely for the Society's silver cup. When it is considered that this lady's birds travelled from Scotland to achieve their triumph, their success proves only the more meritorious. The pullets in the first-prize pen were of the most exquisite plumage imaginable. The third-prize pen shown by the same lady were, on the contrary, light-coloured ones, but of amazing growth. Mr. Fowler's second prize pen, in such a competition, it will be readily supposed was a very first-rate one to hold even that position.

Of *Game* fowls, undoubtedly the Black-breasted Reds were pre-eminent, Mr. Stubbs' pen being as perfect as any one can hope for; nor shall we be surprised to hear of their obtaining a long run of success this season if shown in the splendid condition and feather they just now possess. Mr. Fletcher, of Manchester, and Mr. Julian, of Beverley, were compelled to take subordinate positions on the prize list. In *Duckwings*, the pen of Mr. Fletcher was unapproachable, although the Hon. W. W. Vernon's second and third prize pens were most excellent. Mr. Dawson's Black Game chickens foretell this well-known exhibitor has had a successful breeding season.

The *Hamburgh* classes, contrary to general expectation, were decidedly the weakest classes of the Show, the Gold-spangled being the only exception.

In *Polands*, the Show was excellent; they were such as only Messrs. Edwards, Dixon, and Adkins can exhibit, each variety being perfect.

In *Malays*, also, three such pens were scarcely ever before brought into competition.

In the Extra variety class were first, the best pen of Silkies seen for many years, some perfect gems of the White-footed Bantams, capital Andalusians, and a most unique pen of *Polands*, absolutely "Piles,"—a colour never before exhibited. Mr. Bayley, of Biggleswade, appropriated nearly the whole of the Bantam prizes, taking both the first and second for each variety of Sebrights, also first and second for White ones, again first in Game Bantams, and the like for single Game Bantam cocks. This gentleman's yards of Bantams have evidently not been idle during the present summer.

Of *Ducks*, the Aylesbury were the best shown of any.

The *Geese* and *Turkeys* were triumphs of careful breeding, and do the greatest credit to their respective proprietors. Strange to say, that although very liberal premiums were offered for ornamental water fowl, only a single pen of Spanish Geese were entered. This, among general visitors, was the subject of much astonishment, it apparently being but little known that almost every description of our most beautiful fancy water fowls are at this season entirely out of feather.

The greatest care and attention was paid to the poultry,

and the Meeting was well supported throughout its continuance.

SILVER CUP FOR THE BEST PEN OF FOWLS IN THE SHOW.—Viscountess Holmesdale.

SPANISH.—First, J. R. Rodbard. Second, J. Clews. Third, S. Rohson. Highly Commended, J. R. Rodbard. *Cocks*.—First, H. Lane. Second, J. R. Rodbard. Highly Commended, — Wright.

DORKINGS (Coloured).—First and Second, Viscountess Holmesdale. Third, W. Dolby. Fourth, E. Burton. Highly Commended, H. Lingwood; H. Elvidge. Commended, Viscountess Holmesdale; Rev. J. G. A. Baker; Mrs. F. Blair.

DORKING PULLETS.—First, Viscountess Holmesdale. Second, C. H. Wakefield. Highly Commended, Miss J. Milwood; J. Jardine; W. Dolby; Mrs. F. Blair.

DORKING (White).—First, Rev. G. F. Hodson. Second, H. Lingwood. Commended, Lady M. Legge; Mrs. M. A. Beardmore.

DORKING COCKS (Coloured and White).—First, Viscountess Holmesdale. Second, C. Preest. Third, Mrs. F. Blair. Commended, J. Smith.

COCHIN-CHINA (Cinnamon and Buff).—First, J. W. Kelleway. Second, Rev. C. Spence. Third, G. Fell. Highly Commended, Mrs. T. Stretch. Commended, J. W. Kelleway; Rev. C. Spence; Rev. C. Gilbert.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch. Second and Third, F. B. Walker. Highly Commended, C. H. Wakefield.

COCHIN-CHINA (White).—First, W. Dawson. Second, R. Chase. Highly Commended, R. M. Lord; W. Dawson.

COCHIN-CHINA COCKS (Coloured and White).—First, J. W. Kelleway. Second, C. Wakefield.

BRAMA POOTRA.—First and Third, Mrs. F. Blair. Second, J. K. Fowler. Commended, C. Preest. *Cocks*.—First, C. Preest. Second, W. L. Barclay. Commended, J. Hinton.

GAME (White and Piles).—First, H. Baker. Second, W. Burgess. Third, G. Crofts. Commended, H. Baker.

GAME (Black-breasted Reds).—First, J. Stubbs. Second, J. Fletcher. Third, H. M. Julian. Highly Commended, H. Adney; S. Mathews; H. Snowden.

GAME (Brown-breasted and other Reds, except Black-breasted).—First, H. Snowden. Second, J. Fletcher. Third, withheld.

GAME (Duckwing and other Greys and Blues).—First, J. Fletcher. Second and Third, Hon. W. W. Vernon.

GAME (Blacks and any other Variety).—First, W. Dawson. Second, Hon. W. W. Vernon.

GAME COCKS.—First, S. Mathews. Second, J. Fletcher. Third, J. Stubbs. Highly Commended, A. Heath.

HAMBURGH (Gold-pencilled).—First and Second, Mrs. A. Nuttall. Third, N. Barter.

HAMBURGH (Silver-pencilled).—First, H. Menhall. Second, C. Moore. Third, J. E. Powers.

HAMBURGH COCKS (Gold and Silver-pencilled).—First, withheld. Second, Rev. T. S. Fellows; J. E. Powers.

HAMBURGH (Gold-spangled).—First, J. Roe. Second, G. Brook. Third, — May. Highly Commended, G. Brook.

HAMBURGH (Silver-spangled).—First and Second, J. Fielding. Third, C. Preest.

HAMBURGH COCKS (Gold or Silver-spangled).—First, withheld. Second, Mrs. H. Sharpe.

POLISH (Black, with White Crest).—First and Second, T. Edwards.

POLISH (Gold).—First, J. Dixon. Second, W. Newsome.

POLISH (Silver).—First and Second, G. C. Adkins. Highly Commended, J. Hinton.

POLISH COCKS.—First, T. Edwards. Second, G. Adkins.

MALAY.—First and Second, A. Sykes. Highly Commended, J. J. Fox.

ANY OTHER DISTINCT BREED.—First, W. Bowly. Second, Rev. P. W. Story. Third, C. Coles. Fourth, Mrs. F. Blair. Highly Commended, Mrs. Blair.

BANTAMS (Gold-laced).—First and Second, T. H. D. Bayley. Highly Commended, M. Leno, jun.

BANTAMS (Silver-laced).—First and Second, T. H. D. Bayley. Highly Commended, E. Jones. Commended, M. Leno, jun.

BANTAMS (White—Clean Legs).—First and Second, T. H. D. Bayley.

BANTAMS (Black—Clean Legs).—First, R. Brotherhood. Second, F. Pittit.

BANTAMS (Game).—First, T. H. D. Bayley. Second, J. W. Kelleway. Highly Commended, T. H. D. Bayley; J. Anderson; E. Browne. Commended, J. W. Kelleway; J. Anderson.

BANTAMS.—First, D. Canser. Second, T. Williams.

BANTAM COCKS.—First, T. H. D. Bayley. Second, J. W. Kelleway. Highly Commended, T. H. D. Bayley.

DUCKS (Aylesbury).—First and Second, J. K. Fowler. Highly Commended, P. A. Eagles. Commended, P. A. Eagles; Miss Whally.

DUCKS (Rouen).—First, T. R. Hulbert. Second, Mrs. F. Blair. Highly Commended, T. R. Hulbert; Mrs. F. Blair.

DUCKS (Black).—First, Mrs. M. A. Beardmore. Second, J. W. Prize.

GESE (White).—First and Second, J. K. Fowler.

GESE (Grey and Mottled).—First, W. Dolby. Second, Mrs. F. Blair. Highly Commended, Mrs. F. Blair.

TURKEYS.—First, J. Smith. Second, Rev. P. W. Story.

ORNAMENTAL WATER FOWL.—Prize, Rev. P. W. Story.

PIGEONS.

POWTERS OR CROPPERS (Any Colour).—First, R. Fulton. Second, T. Evans. Third, F. G. Stevens. Very Highly Commended, T. Evans; R. Fulton. *Hens*.—First, T. Evans. Second, R. Fulton. Third, F. G. Stevens. Highly Commended, T. Evans; R. Fulton. Commended, F. G. Stevens; C. T. Samuel.

CARRIERS (Black and Dun).—First and Second, F. G. Stevens. Third, F. Else. *Hens*.—First and Second, F. Else. Third, F. G. Stevens. Highly Commended, W. H. Edmonds. Commended, F. G. Stevens.

CARRIERS (Any other colour).—First, W. H. Edmonds. Second, J. L. Ord. Highly Commended, W. H. Edmonds. *Hens*.—First, J. S. Ord. Second, W. H. Edmonds.

DRAGONS.—Prize, F. Else; T. Esquilant.

ALMOND TUMBLERS.—First and Second, F. Else. Third, H. Yardley.

MOTTLES (Short-faced).—First, F. White. Second, F. Else. Commended, H. Bance.

BALDHEADS (Short-faced).—First, T. Esquilant. Second, J. Edge. Commended, F. G. Stevens.

BEARDS (Short-faced).—First, T. Esquilant. Second, J. Percivall.

TUMBLERS (Short-faced—Self Colour).—First, W. H. C. Oates. Second, J. Morris.

KITES, AGATTS, DUNS, AND GRIZZLES.—Prize, J. Foid.

JACOBINS.—First, J. Morris. Second, F. G. Stevens. Commended, F. Else.

OWLS.—Prize, F. Else.

OWLS (Yellow, or any other Colour).—Prize, F. Else. Highly Commended, H. Yardley; J. Morris.

NUNS.—First, C. Bulpid. Second, F. Else. Commended, Rev. A. G. Brooke.

TURBITS.—First and Third, F. Else. Second, F. G. Stevens.

FANTAILS.—Prize, J. W. Edge.

FANTAILS (White).—Prize, H. Yardley. Highly Commended, F. Else.

Commended, F. Key; J. Morris.

FANTAILS (Blue).—Prize, J. W. Edge.

BARES.—Prize, F. G. Stevens.

BARES (Yellow, or any other Colour).—Prize, F. G. Stevens.

MAGPIES.—First, J. Percivall. Second and Third, F. Else.

TRUMPETERS.—Prize, F. Else.

TRUMPETERS (White, or any other Colour).—Prize, F. G. Stevens. Highly Commended, F. Key; H. Yardley. Commended, Rev. A. G. Brooke; F. Else.

SPANISH AND LUGHERN RUNTS.—First, F. G. Stevens. Second, T. D. Green. Highly Commended, T. D. Green.

FOR ANY NEW OR DESERVING VARIETY NOT BEFORE MENTIONED.—First, H. Yardley. Second, J. Percivall. Third, J. Owens. Fourth, withheld.

RABBITS.

LONGEST EARS.—First, J. Cranch. Second, W. Griffin.

BLACK AND WHITE.—First, J. Haile. Second, R. Cook.

YELLOW AND WHITE.—First, Messrs. Hall & Co. Second, W. Griffin.

TORTOISESHELL.—First, J. Haile. Second, A. Stehman. Commended, J. Haile.

BLUE AND WHITE.—First, C. Sillen. Second, J. P. Miller. Commended, C. Sillen.

GREY AND WHITE.—First and Second, R. Cook. Commended, J. Haile.

SELF COLOUR.—First, C. Sillen. Second, G. Jones. Commended, J. G. Quick.

WEIGHT.—First, Mrs. F. Blair. Second, J. K. Fowler.

FOREIGN.—First, E. Terry. Second, F. S. Angel.

JUDGES.—*Poultry*.—Mr. Hewitt, Eden Cottage, Sparkbrook, Birmingham; Mr. James Monsey, Norwich. *Pigeons*.—Mr. Bellamy, London; Mr. D. Wolstenholme, London; Mr. W. B. Tegetmeier, Muswell Hill, London. *Rabbits*.—Mr. Terry, Lambeth; Mr. Lock, Walworth.

ADDLED EGGS—SEBRIGHT BANTAMS.

On perusing my communication to your Journal as to chilling of eggs, I find an error which may lead your correspondents into the idea that the hen had been chilling her eggs with a vengeance. In page 156, line 13, instead of "I found one egg chilled," &c., read "I found one egg *chipped*," &c.

My last sitting of eggs for this season were due to-day (Sebright Bantams), all addled. Will any of your correspondents who keep this breed be kind enough to state if they have been alike unfortunate? I cannot help thinking there must be something peculiar in Sebright Bantams. Out of about sixty eggs I have only had, I think, six chickens; whereas the eggs from my other breeds have been this year most fertile.

The Bantam eggs were all from a cock and three hens (birds of 1862), and no other fowls kept with them.—EYESHAM.

LEICESTERSHIRE AND WALTHAM POULTRY EXHIBITION.

THIS Show is held conjointly with a show of cattle, horses, cheese, and roots. The flowers exhibited this year also were of great merit, all which combined drew together an unusual attendance. The Leicester and Waltham Poultry Show, however, this year laboured under extraordinary disadvantages, for not only were the Pocklington, the Halifax and Calder Vale, and one or two minor Shows held simultaneously with it; but a still more unfavourable drawback was the fact, that the great Poultry Show at the London Agricultural Hall was also carried out at the same date. This latter Society offering the most liberal premiums, of course enticed many an exhibitor to try his luck at Islington who otherwise might have been found competing at the Leicester and Waltham Poultry Show.

Besides pecuniary benefit, it is but an almost universal trait of human nature to prefer the honour of success at the larger Exhibition, and to value a prize proportionately to

the absolute difficulties that stand in the way of its attainment. Feelings of this character no doubt prevented many an entry for Leicester that under other circumstances would not have been wanting. In fact, we know some classes were very materially lessened from this sole reason.

The *Spanish* class of old birds was a weak one, every pen being somewhat faulty, and condition was wanting throughout. One exhibitor most strangely (if expectant of success), absolutely penned a rosy-combed hen in this competition. The class for young *Spanish* fowls consisted of but two pens, but both of these deserve very favourable mention.

The class for old *Grey Dorkings* was indifferent, none taking even a commendation, save the two winning pens. The *Grey Dorking* chicken class proved one of the most extraordinary "mixed medlies" that ever was placed before any arbitrator. Perfectly bright yellow legs that would have given a positive blaze of success attached to a pen of Malays or Cochins, here glittered unavailingly; whilst the additional Dorking-toe was evidently eschewed altogether by another competitor as "quite unnecessary, as he said the development only encumbered the fowl and hindered it when walking." The *Silver Grey Dorkings* were so very faulty in colour in both the classes, that half the prizes were withheld. One pen contained a very unusual specimen—viz., a cock so well booted and leg-feathered, that it would have caused even a *Brahma Pootra* for the future to forewear all leg-coverings. The *White Dorkings* were really good, although the chicken class was very select as to the number of entries.

The adult *Cochins* were inferior, but the first-prize chickens (*Partridge-coloured* ones), were particularly good. In this class an "old hen" was attempted to be palmed off for a chicken—of course, leading to immediate disqualification by the Judges. The *White Cochins* should never be shown with green-tinged legs, the objection to which is always fatal to success. This we mention, as evidently many otherwise good pens were thrown out completely through want of care on this point alone.

The *Duckwings* were the best shown of the *Game* fowls, though the first-prize *Black Reds* would have been thought much of if shown in condition.

The *Hamburghs* were few in numbers. In *Golden-spangled* a well-deserved first prize was allotted; but, strange to say, some half-bred *Malays*, and again a pen of actually "laced" (not "spangled" at all) birds, were entered. In the *Pencilled* ones matters were far better. In the commended pen of *Gold-pencilled* chickens were exhibited the best cockerel and pullet, by far, we have seen this year, but mated to a second pullet so indifferent, that the spit would be the most suitable position of any for her future appearance. Some good *Silver-spangled* were shown. In both the *Silver-pencilled Hamburgh* classes the prizes were withheld, save one second. They were the two worst classes we ever saw of this breed.

Although not a *Sebright Bantam* was present, the *Black* and the *Game Bantams* were well shown.

Many of the *Aylesbury Ducks* were faulty in the bills—a shortcoming quite incapable of compromise. As good *Rouen Ducks* were shown as could be desired; in fact they would have added to the credit of our most popular meetings.

In *Geese*, the competition was strong; but we much fear a disregard to the sexes shown pervaded at the least one pen.

In *Turkeys*, the *Cambridge* breed took highest place, and capital *Norfolk* second.

Golden and *Silver Chinese Pheasants*, for which special prizes were given, mustered in numbers, and they were exceedingly well shown.

The *Pigeon* classes, as a whole, were very meritorious; and among the *Rabbits* was one of the best *Greys* we have seen for years past.

The accommodation of the poultry was most amply provided for by the Committee, the tent being spacious and airy.

SPANISH.—First, M. Brown, Ab Kettlebr. Second, J. W. Argyle, Leicester. *Chickens*.—First and Second, M. Brown.

DORKINGS (Coloured).—First, J. Smith. Second, A. Guy, Eaton. *Chickens*.—First, B. Everard, Bardon Hill House. Second, J. Sheffield, Geddington Grange.

DORKINGS (Silver-Grey).—Second, Sir A. G. Hazlerigg, Noscley Hall.

First, Withheld. *Chickens*.—First, R. Dutton Miles, Keyham. Second, Withheld.

DORKINGS (White).—First, R. D. Miles, Keyham. Second, Capt. Buckley, Desford. *Chickens*.—Prize, R. D. Miles, Keyham.

COCHIN-CHINA (Coloured).—First and Second, H. C. Woodcock, Rearsby. *Chickens*.—First, A. Guy, Eaton. Second, H. C. Woodcock, Rearsby.

COCHIN-CHINA (White).—Second, H. E. Emberlin, Humberstone. First, Withheld. *Chickens*.—First and Second, T. Sheppard, Humberstone.

GAME (White Piles and Light Colours).—First, H. W. White, Leicester. Second, G. Cooper, Seagrave. *Chickens*.—First, B. Everard, Lardon Hill House. Second, A. Guy, Eaton.

GAME (Red and other dark colours).—Second, B. Everard, Bardon Hill House. First and Third, Withheld. *Chickens*.—First, B. Everard. Second, Sir W. De Capel Brooke.

HAMBURGERS (Golden-spangled).—First, H. E. Emberlin, Humberstone. Second, Withheld. *Chickens*.—First, H. E. Emberlin. Second, Captain Buckley, Desford.

HAMBURGERS (Golden-pencilled).—First, Captain Buckley, Desford. Second, J. Jacques, Birstall Hill House. *Chickens*.—First, A. Houghton, Asfordby. Second, T. H. Pares, Kirby Frith. Highly Commended, Captain Buckley. Commended, T. H. Pares.

HAMBURGERS (Silver-spangled).—First, W. Exton, Narborough. Second, R. D. Miles, Keyham. *Chickens*.—Prize, Captain Buckley, Desford.

HAMBURGERS (Silver-pencilled).—Prizes withheld. *Chickens*.—Prize, T. Charlesworth, Leicester.

BANTAMS (Game).—First and Second, H. C. Woodcock, Rearsby. BANTAMS (Black).—First, J. Goodyear, Cawthorpe. Second, Withheld.

DORKING COCK (Any colour).—Prize, J. Smith.

DUCKS (White Aylesbury).—First, H. E. Emberlin, Humberstone. Second, W. Carver, Ingarsby. Highly Commended, W. Carver. Commended, H. E. Emberlin.

DUCKS (Any other variety).—First, T. Burnaby, Pipewell (Rouen). Second, S. Pool, Thorpe Arnold Lodge, near Melton (Albridge). Highly Commended, T. Burnaby (Rouen). Commended, H. Wilson, Broughton Astley; H. L. Powys-Keck, Stoughton Grange.

GESE—First, W. Kirk, Wymondham (Toulouse). Second, W. Winterton, Wolvey Villa.

TURKEYS.—First, A. Guy, Eaton (Cambridge). Second, H. L. Powys-Keck, Stoughton Grange.

PHEASANTS (Golden).—Prize, S. Lennard, Leicester. Highly Commended, R. D. Miles, Keyham.

PHEASANTS (Silver).—First, R. D. Miles, Keyham. Highly Commended, S. Lennard, Leicester. Commended, J. Buck, Leicester.

POULTERS.—*Poulters* (White).—Prize, J. Langham, Delgrave. *Poulters* (Any other colour).—Prize, Rev. R. W. Fisher, Aiton Cheshire. Commended, Rev. R. W. Fisher. *Carriers* (White).—Prize, H. E. Emberlin, Humberstone. Highly Commended, H. E. Emberlin. *Carriers* (Any other colour).—Prize, J. Langham, Delgrave. Commended, H. E. Emberlin; J. Langham. *Tumblers*.—Prize, Rev. R. W. Fisher. Commended, J. W. Argyle, Leicester. *Fantails*.—Prize, H. E. Emberlin. Commended, J. Langham. *Turbits*.—Prize, J. Langham. *Turbits* (Red).—Prize, H. E. Emberlin.

RABBITS.—*Hares* 4 Weight.—Prize, J. N. Dixon, Leicester. *Greatest Length of Ear*.—Prize, J. N. Dixon. *Any other kind*.—Prize, W. Chamberlain, Desford.

The Judges appointed were Mr. W. Dolby, of Horse Grove, Rotherfield, Tonbridge Wells; and Mr. Edward Hewitt, of Sparkbrook, near Birmingham.

FOWLS AT NIGHT.

FOWLS that have been allowed to roost out may continue to do so; and the first alteration in the weather, the feeling of freshness consequent on rainfall and on the diminishing hours of sunshine, need not lead to any change of management. With the head tucked under the wing, the body drawn into its smallest compass, the feathers so compact and close that nothing can penetrate, perching on one bough of a tree and under another, we believe a healthy fowl can bear any amount of rain, not only without injury, but almost without feeling it—certainly without any other than the outer feathers being wetted.

Out-door roosting has many advantages: during summer and autumn it is certainly healthier for them; they are less subject to vermin; they grow faster, and are stronger than those that are more cared for. Yet it is now well, so far as it can be done, to draw them by degrees nearer and nearer to the place where they will roost during the winter. When nights are long and cold, and foxes are dispersed about the country, it is desirable they should be sheltered at night. We cannot forget the scene that met us one fine winter's morning. All the best fowls of one yard were slaughtered and laid about, and the road to the fox's kennel was marked by here a White Cochins, there a Buff, and then a Spanish, next a Bantam.

While on the subject of depredators, we can corroborate that which is said by one of our correspondents about hedgehogs. We put a few early chickens in a sheltered orchard. There were four hens with good broods. One or two chickens disappeared every night without our being able to tell how. There was a scream and a commotion, yet, before we got there, all was still, save that the hens

were muttering. We determined to watch; after a time the chickens rushed out, the hen fought for a moment, and then, screaming, tried to escape. We ran to the coop and turned a strong light upon it. The whole affair had lasted but a minute, but there lay two chickens dying, both bitten through the neck, and the assassin, in the shape of a hedgehog, lying rolled up. We killed him and lost no more chickens. He had taken nine.

POCKLINGTON POULTRY SHOW.

THIS Show was held on Tuesday, August 25th. The following is the list of the awards:—

SPANISH.—First and Second, Miss E. Beldon, Gilstead, Bingley. *Chickens*.—First, H. A. Hudson. Second, J. Reynolds, South Cliffe. (Very good class).

DORKINGS.—First, E. Smith, Middleton, Manchester. Second, Miss E. Beldon, Gilstead, Bingley. *Chickens*.—First, O. A. Young. Second, Eldridge, Bishop Wilton. (Poor except the first-prize pen).

COCHIN-CHINA (Buff, Lemon, or Cinnamon).—First, H. & G. Newton, Garforth, Leeds. Second, E. Smith. Commended, C. T. Bishop, Leaton, Nottingham; H. & G. Newton; R. Clark, South Dalton.

COCHIN-CHINA (Any other variety).—Prize, R. White, Bromhall Park. *Chickens*.—First, H. & G. Newton. Second, J. Appleton, Pocklington. (This class was one of the best in the Show).

GAME (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, Miss E. Beldon. Highly Commended, H. Adams.

GAME (Duckwing and other Greys).—First, H. Adams. Second, A. Cattle, York.

GAME (Any other variety).—First and Second, H. Adams. *Chickens*.—First, H. Adams (Piles). Second, J. Rennison.

HAMBURGERS (Silver-spangled).—First, S. Campling, Cottingham. Second, Miss E. Beldon.

HAMBURGERS (Golden-spangled).—First, Miss E. Beldoo. Second, G. Holmes, Duffield.

HAMBURGERS (Silver-pencilled).—First, Miss E. Beldoo. Second, O. A. Young.

HAMBURGERS (Golden-pencilled).—First, Miss E. Beldon. Second, O. A. Young. *Chickens*.—First, H. A. Hudson. Second, O. A. Young.

POULTERS.—First, Miss E. Beldon. Second, O. A. Young.

BANTAMS (Game).—First, G. Holmes. Second, R. M. Stark, Hall.

BANTAMS (Any other variety).—First, Miss E. Beldon. Second, R. M. Stark.

GESE.—First, O. A. Young. Second, Mrs. Croft, Plunkham.

DUCKS (Aylesbury).—First, R. M. Stark. Second, O. A. Young.

DUCKS (Any other variety).—First, R. M. Stark. Second, J. Braim, Pickering. Highly Commended, J. R. Jessop.

TURKEYS.—First and Second, Mrs. W. Rickell, Watter Wold.

GUINEA FOWLS.—First, O. A. Young. Second, W. Dorsey, Watter.

SINGLE COCKS.

GAME.—First, H. Adams. Second, J. R. Rennison.

SPANISH.—First, Miss E. Beldon. Second, S. Robson.

DORKING.—First, R. M. Stark. Second, O. A. Young.

COCHIN-CHINA.—First, R. White, Broomhall Park. Second, O. A. Young.

HAMBURGH.—First, Miss E. Beldon. Second, O. A. Young.

BANTAM.—First, Miss E. Beldon. Second, W. Gulton.

PIGONS.—*Poulters or Croppers*.—First, S. Robson. Second, Miss E. Beldon. *Tumblers*.—First, Miss E. Beldon. Second, J. W. Edge, Birmingtonham. Highly Commended, H. Yardley. *Burbs*.—First, Miss E. Beldon. Second, H. Yardley. Highly Commended, T. Ellington, Woodmansey. *Jacobins*.—Prize, G. Spink. *Fantails*.—First, Miss E. Beldon. Second, J. W. Edge. Highly Commended, W. Carlton, Howden; T. Ellington. *Trumpeters*.—First, S. Robson. Second, Miss E. Beldon. Commended, W. Carlton. *Owls*.—First, Miss E. Beldon. Second, J. W. Edge. *Turbits*.—First, H. Yardley. Second, J. R. Jessop. *Carriers*.—First, S. Robson. Second, H. Yardley. *Any other variety*.—First, Miss E. Beldon. Second, J. W. Edge.

CAGE BIRDS.—*Belgian Canary*.—First, Miss Small, Howden. Second, J. Moore. *Marked Canary*.—First, Blacker. Second, G. Harrison. *Pair of Canaries*.—First, Miss Small. Second, G. Harrison. *Canary* (Any other variety).—First, J. Baines. Second, W. Carlton. *Male*.—First, G. Harrison. Second, R. Harrison. *Redcap*.—First and Second, W. Carlton.

EXTRA STOCK.—Mrs. W. Rickell (White Geese). — Sallow, Nurnburnholme (White Robins).

The Judges were Mr. John Crossland, Jun., Wakefield, and Mr. George Jackson, York.

AGE OF QUEENS—EFFECTS OF FUMIGATION.

I REGRET that I am unable to furnish "A HAMPSHIRE BEE-KEEPER" with any positive information regarding the longevity of the queen bee. Although a tolerably close observer of apian facts since 1840, when I first kept bees, my career as a strictly scientific apian dates only from the introduction of the Ligurians in 1859. Since that time I have been, so to speak, on visiting terms with every queen in my apiary, know the age, and can describe every peculiarity in the personal appearance of each; but, unfortunately, accidents to queens in leading off swarms, and regicides committed by their subjects, have thus far frustrated all my endeavours to obtain accurate information on the point in question. The senior queen in my apiary is now two years

old, and certainly shows no signs of decrepitude, but I have a strong impression that "A LANARKSHIRE BEE-KEEPER" has been deceived by an accidental resemblance between two successive monarchs, and that he is, therefore, mistaken in believing that a queen has survived and remained fertile during seven years.

Would Mr. Lowe be kind enough to favour us with the desired information? In the autumn of last year he forwarded to me a couple of living queens for microscopic examination. One of these he informed me had ceased laying altogether, whilst the other, having returned to the drone-laying condition of a virgin, afforded the strongest possible confirmation of the truth of parthenogenesis.* If Mr. Lowe will oblige us by stating the age of these queens it will at once decide the question.

My suspicions as to the injurious effects upon bees of stupefaction by means of fungus were first aroused by finding that a repetition of the operation a few days afterwards was always fatal, proving that the bees must have been in some way weakened by the first fumigation, although they appeared at the time to have perfectly recovered from it. When I afterwards found that colonies of bees expelled from their hives in this manner, and furnished with combs and plenty of food, invariably dwindled away, my impression became confirmed, and I spared no pains until I had mastered the art of driving, which renders fumigation unnecessary, and is free from all objection.

I have never found bees slaughtered on their return from a removed snper, and should suspect some error in management were such an occurrence to take place.

I have to thank "A HAMPSHIRE BEE-KEEPER" for his kind sympathy. The good of others was the sole object I had in view when I made my misfortune public, and "A HAMPSHIRE BEE-KEEPER" administers the best consolation when he declares that he has already benefited by the warning given by—A DEVONSHIRE BEE-KEEPER.

HONEYDEWS—FOUL BROOD.

COLONEL NEWMAN in his last communication spoke of honeydews being abundant this year, leading us to infer that his bees, or the bees generally in the neighbourhood of Cheltenham, had profited by them to the filling of their honeycombs. May I ask the gallant Colonel if he actually saw the bees collecting those dews in such numbers as to warrant him in believing that any considerable quantity of this exudation or excretion was actually stored up as honey by the bees? Also I should be glad to know what trees the bees frequented in search of it. Only once in my life have I had ocular demonstration to the fact of bees sipping this honeydew; nor have I met with any apianian or naturalist who had more experience than myself. Some ten or eleven years ago I put the question in the pages of THE COTTAGE GARDENER, and, so far as I can remember, I myself was the only person who had seen bees apparently collecting the honeydew, although more than one writer stoutly asserted the fact that they do collect it. I must profess myself to be still incredulous with regard to these dews, so far at least that bees make any use of them in ordinary years. In bad seasons, when bees are starving, they will feed upon anything sweet which is not offensive to them; but I doubt whether they will touch honeydew when anything else in the shape of food is to be had by them, and it remains a question if they store it in their hives. If this be correct, bee-writers generally have copied from each other a mere tradition, when they speak so bravely about the extraordinary activity of bees during the prevalence of honeydew.

As to the other question of foul brood now being discussed in your pages, I feel strongly persuaded that Mr. Woodbury has fully made out his case as to this being a disease of a distinct type. Here are no "mere surmises or conjectures"—no mere "accepting for truths the dicta of others," but facts very patent, and proofs, as they appear to me, very satisfactory. Like Mr. Edwards (who by the way writes like a man who is thoroughly up to the scientific and profitable management of bees), "I have had more or less of chilled brood under various circumstances," and no check to

the bees has resulted from it, the bees quietly clearing out their cells, but generally I have had also such brood become corrupted in the hive, and the bees nevertheless, if sufficiently populous, have thriven in spite of it; but nothing like the disastrous experience of Mr. Woodbury has come under my notice hitherto. Here is a case of hive after hive in various conditions catching the infection till an entire apiary is hastening to destruction. Not only so, new hives, fresh and well peopled, are brought from a distance, and they, too, are attacked. The virulence of the disease is also remarkable, and the rapidity with which the evil spreads. Mr. Lowe seems to forget that Mr. Woodbury has been for several, I may say for many, years an experimental apianian (all thanks to him for it), and repeating again and again the very ingenious and admirable process to which Mr. Lowe so strongly excepts; but nothing like this disease has ever come across him before. I must add that in the interests of our favourite pursuit, the tone and style of Mr. Lowe's recent communication are in my poor opinion much to be regretted. I asked myself directly I read it, What personal disagreement can have arisen between the two gentlemen to account for this philippic?—B. & W.

REMOVING BEES TO THE HEATHER

SINCE you published my directions for removing bees to the moors in THE JOURNAL OF HORTICULTURE of July 21st, I have had several letters, showing how carefully my instructions should be carried out to prevent the combs in swarms breaking down and drowning the bees in their own honey. And as my object is to preserve the lives of these useful interesting little creatures, as well as to encourage bee-keepers by showing them how to make a good profit out of their bees, I think I cannot do better than give them the correspondence I have had with a Lincolnshire bee-keeper, which clearly shows how easy it is to remove swarms even with combs only partly made, if my instructions are strictly carried out.

"MR. CARE,

"Lincolnshire, July 29th.

"Dear Sir,—Previous to seeing your instructions in the paper, how to remove bees to the heather, I had removed thirteen swarms to the moors, and the combs broke down in several of them, and the bees were all drowned in their own sweets, and were totally destroyed. The plan I pursued was, to take the hives gently off the stands, and tie them up in a thin piece of calico, and they were conveyed very steadily to the moors. But you appear to prefer carrying them turned upside down. My bees are in flat-topped straw hives. I should esteem it a great favour if you will drop me a line with some further instructions, as I want to take about twenty more hives to the heather. Yours, &c."

In reply I said—

"I am sorry you have had the misfortune to lose some of your hives of bees, as it is very discouraging. The new combs, especially in late swarms, are as brittle as glass, and break down with the least shake when heated, and even fall with their own weight if they have any honey in them, as the bees when made up with the finest calico grow excited, and the heat ascending to the top of the hive soon heats the comb and they give way.

"But I think if you will follow my directions, you will meet with no further accidents, as I have taken my bees to the moors for many years, part of the way by the railway, and then six miles over a very rough country, on and suspended under a carriage, and I took them again last Saturday without any accident.

"Fasten your bees, especially your swarms, in a cover of very open net (strong cap-net will do), with holes in it just small enough to prevent the bees escaping, and when tied securely turn the hive gently up, but mind that the edges of the combs are at the bottom part as you turn the hive over, otherwise the combs will probably either bend or break with their own weight and that of the bees upon them. When turned bottom upwards, the combs all rest upon their own foundation, and the heat always ascends, and so escapes through the net, and the inside of the hive is kept cool. Swarms always ride the best suspended. With old hives the same amount of care is not necessary, as the bees varnish their combs with a sort of glue, and when they have had brood

* The result of my examination is related in page 547, of the third vol. of THE JOURNAL OF HORTICULTURE.

in the combs, the cocoon left in the cells again strengthens them, so that they become nearly as tough as leather, and you can knock them about as you like, provided you give them plenty of air.

"It will be a gratification to me to hear that I have been the means of saving you your property, and the lives of the poor bees, and am, &c.—WM. CARR, *Clayton Bridge Apiary, near Manchester.*"

"MR. CARR,

"Lincolnshire, August 13th.

"Dear Sir,—It is impossible for me to return you sufficient thanks for your information about taking my bees to the heather. I purchased some strong cap-net and conveyed my bees as you directed, and I had not a single accident, and they all arrived safely at the moors. I had some of them suspended, and others put on some straw in a light cart, and the pony trotted very quickly for about five miles over a very rough road, and as you said, the hives were kept cool, and there was not a single comb damaged in any of the swarms whatever. If you should at any time be so unfortunate as to lose your bees, I shall have great pleasure in presenting you with a new stock, and am, &c."

FOUL BROOD—WOODEN HIVES.

BEING a victim of this greatest of all plagues to the apianian, and consequently desirous of knowing as much as possible respecting it, I have been subjecting portions of the infected combs to microscopic examination, and the result is that I am led to believe that whatever may be the anterior cause, the disease itself is the result of the action and presence of fungi. I have found in the bottoms and sometimes on the walls of the cells minute whitish spots, irregularly distributed and of various sizes, the largest not more than 2 lines in diameter, and which on being viewed under various magnifying powers of from 200 to 600 diameters, present the appearance of waxy circles composed of globular particles, and reminding one in appearance of the white cloud cumuli, sometimes visible in bright but stormy weather. In the most highly developed specimens these rings of globules seem to leave the interior space quite vacant, while in those of smaller size the masses appear more or less solid. This I take to be a fungus; and both its appearance and effects seem to me in unison with those of fungi generally, and I should be very glad to know the ideas of more experienced apianians on the matter, believing that a correct apprehension of the nature of the disease will go very far towards suggesting remedial and curative measures. The subtle nature of the spores of fungi is well known, and the globular development is also very common in many classes of these pseudo-vegetables. The circular distribution is a feature conspicuous in some fungi, and their absorption of oxygen and distribution of carbon may well be supposed to be highly detrimental to animal life, especially in so confined an atmosphere as the interior of a hive. It may be that this is not sufficient to destroy the vital powers of fully-developed bees perpetually passing into fresh air; but when it is at work in so confined a space as the sealed cell of the bee-crysalis, it may be sufficient to prevent further growth, and thereby produce "abortive brood."

Fungi are thought by some physiologists to be capable of being evolved from animal or vegetable decomposition. Is it not possible, therefore, that chilled brood in the process of putrefaction may some time or other have produced the fungus? Once produced, its dissemination on my hypothesis of its nature is but a matter of course. That the disease is infectious no one who has been unfortunate enough to have any experience of it can doubt, and this may easily arise from the diffusion of the spores by means of the bodies of bees in passing from hive to hive.

I think Mr. Woodbury has been unjustly suspected by Mr. Lowe and others of having produced the disease by over-experimenting. It has occurred with me in two swarms of black bees that came off naturally, and neither parent hives nor progeny had ever been the subjects of the mildest inspection or process. I attribute their failure to their proximity to the Ligurian hive received from Exeter in the spring, whose diminished numbers and activity rendered it an easy prey to marauders of any description, and some of

which pirates, doubtless, were denizens of the two swarms that subsequently became victims.

I should like to corroborate the opinion of "A LANARKSHIRE BEE-KEEPER" as to the superiority of wooden hives. Like him, I have for some years had both kinds in use. The wooden ones, being home-made, are quite innocent of any virtues commonly deemed necessary, excepting strength, and I never yet had a casualty with them, though exposed to all weathers, which is more than I can say of some of my straw hives, whether protected or exposed. It seems to me that success in bee-keeping depends on something not affected either by shape or material of hives.—G. F. B., *Spalding.*

BEE-KEEPERS OF THE OLD SCHOOL— FOUL BROOD.

WHILE I do not doubt the sincerity of the sympathy manifested by your correspondents towards Mr. Woodbury in his difficulties with foul brood in his apiary, still I cannot help thinking that some of the old-school apianians—those who are averse to all changes—are like many of those who, witnessing the first ship propelled by steam, declared, with a knowing shake of the head, that it would "never do," was "contrary to custom," and "against nature." Why, it went in spite of adverse winds; and notwithstanding the ships did make voyages to other countries and back, they would fail some day. And how these people would chuckle over the first disaster which occurred to the said ship! sorrowing, I have no doubt, for the sufferers, but pleased at the same time that their pet notions had been verified by the (to them) apparent failure. It was the same with Harvey when he announced his theory of the circulation of the blood; the same with Dr. Jenner when he declared vaccination to be a remedy for smallpox, because it was "against nature." And it was not the ignorant, but the learned as well, who joined in the cry against all improvements. Whether based on sound principles or not, it was all the same to them—it interfered with their preconceived notions of what was "against nature."

And it appears to be the same now to all those who attempt to go beyond the beaten track, as in the case of Mr. Woodbury—one who has always been willing to lend a helping hand or give advice to any who asked for it concerning their apiaries; but as soon as he has a failure in his own apiary, and asks for advice, he has a host of critics about his ears, telling him it is all owing to his own management—he is all against "nature"—he uses too much science to accomplish his ends—he will not let well-doing alone. He may well exclaim, "Save me from my friends!"

When he asks for intelligent assistance, he is told by Jonas Jackson that he ought not to overlook what the people do in Cheshire, "not to neglect telling his bees that a relation or friend has ceased to live," and such nonsense. But surely Jonas Jackson is joking when he asks him to perform such absurdities. I pity the darkness of mind which must possess the people of Cheshire if they believe in such mummeries; and I would rather believe that Jonas Jackson has drawn the picture a little too strong, that he may enjoy the pleasure of the idea that non-interference with the bees is still the best plan.

And even my friend Mr. Lowe cannot resist giving Mr. Woodbury a poke in the side, attributing all his failures to excessive meddling with the natural habits of his bees, and doubts that it is really a disease with which Mr. Woodbury is troubled in his apiary.

I will now relate a few cases of foul brood—not in my own apiary, as I am happy to say I never had it, but in that of a neighbour who lives about a quarter of a mile from this, and whose troubles with foul brood I have been a witness to for eight years back; and during all that time, until I saw Mr. Woodbury's first article on the subject, like Mr. Lowe I believed it to be caused by a chill to the young brood. My neighbour, however, would never admit it, having tried plan after plan to get clear of it, and all had failed. He has kept bees upwards of thirty years, has paid great attention to them, has read few works (if any) on the subject, and is, perhaps, the best manipulator of bees to be found. All bees seem to know him—at least, they do not sting him as they do others; and we have dubbed him Professor on account of

his knowledge of bees and their habits, and he would rather take a lot of bees than a hen in his hands. I am compelled, therefore, to give his experience on foul brood, as it bears much against Mr. Lowe and his theory, and may be useful to bee-keepers.

1st. It is now eighteen years since he had a fresh stock-swarm from me, and ten years ago since he saw the first symptoms of foul brood. Eight years ago he had a stock swarm from me in the spring, which gave off a top swarm in June, and put it into a hive of his own which had died that spring, but previously cutting out every part of the comb affected, leaving nothing but honeycomb in the top. The swarm did well enough, to all appearance, till the autumn. On examining it he found all the young combs affected like the old stock. Having lost his young queen, and having another of his own which had foul brood, with a super on it partly filled with honey, but no brood, he drove all the bees and queen into the super, and put it on the top of the old and clean stock which he had from me, and the result was again foul brood in the autumn.

2nd. In the following spring he bought a stock-hive from a neighbour who lived half a mile from him. It likewise was affected with the disease. Since then he has bought other three hives from two neighbours about two miles apart, and each of them had foul brood. One of them gave off a fine swarm, which filled a super of honey; but it, too, was affected in the autumn. This was the first young swarm which became affected during the summer—all the others were affected in the following spring.

3rd. Last autumn he had three old stocks very much affected. He cut out all the foul comb from one hive, leaving only the honey in the top, and drove the bees out of the other two, killing the two queens, and put all the bees into the hive which had been cleared of foul comb, and fed it this spring. In July he examined it and found all the new comb and old comb diseased from top to bottom, and was compelled to melt it all down.

4th. Two years ago he and I exchanged hives with each other. The one I had from him died in the winter, which prevented us from carrying out the plan of trying if changing the situation would have any effect in removing the disease; and perhaps it was as well for me that it did die, as all my others might have been injured by it. At that time I had no fear whatever, but I would not do such a thing again on any account.

The one he had from me did not give off a swarm, and in the autumn this, too, was affected as much as the other. The only reason he could assign for it was, that during the month of May the bees from his own stocks began robbing—for one day only, but ceased the following, he having prevented them.

These are some of his trials which have been going on for ten years, and his is not the only case. We are aware of eight neighbours within a circuit of three miles from this whose stocks are all affected less or more; and we know of others who have had stocks of forty in number and who have not one at this time. And let me add for the information of Jonas Jackson and Mr. Lowe, that these individuals do not interfere with the natural habits of their bees, but merely put them into a hive when they swarm, and take the honey when they can get it, and some of them did not know they had foul brood until it was pointed out to them.

I will now state the 5th and last case at present. Three years ago he bought a stock swarm from a neighbour who was parting with his whole stock, and which had been long famed for being good honey-gatherers, and it was perfectly clean. The produce of that hive is still clean with the exception of one swarm, a second, which he united with one of his own from the foul stock, having killed its queen, retaining the queen from the pure stock; and it likewise has foul brood, but not so bad as the others. It was fed also with honey from his diseased hives.

If these five cases, which are undoubted facts, along with Mr. Woodbury's experience, do not prove that it is a disease, then what is it? If it is caused by chills of the brood in the first instance, why is it not among mine? There cannot be a degree of difference of temperature between my neighbour's situation and mine. He has tried the covering of some, first with sheets of hair felt 2 inches thick, and then a covering of straw over all, and

the whole in a house open to the south. He has tried them also without any covering whatever, but with no apparent difference. If it is by chilling the brood we should find it most on the outside of the combs, and the centre and top of the hive free, as the bees will go there as they retire from the cold; but in his case it is always as bad in the centre and top as on the outer edges.

There is another remarkable point in his case, and which I do not think Mr. Woodbury has noticed—that no drone-brood has ever been affected; if by cold, then the drone must be more hardy than working brood. In my neighbour's case it cannot be said that he exposes them to any chills whatever, as he is very cautious in this respect. I expose mine much more than he has ever done without any bad effects, and I am disposed to think that the brood is more hardy than we imagine. I had a bar-comb of brood lately, in all stages, which fell out while handling it. I might have fixed it again; but my neighbour, being with me at the time, urged me not to do so, as the brood might get chilled, and so propagate the disease among mine. I put the comb into a vinery on a shelf, where the temperature would be as low as 50° at night, with full air on night and day. I used to amuse myself feeding the young grub with a little honey and bee-bread mixed, putting it into the cells on the point of a piece of straw. These grubs lived for two weeks, and at last came out of the cells altogether, crawling about on the shelf till they died; and numbers of the young bees, which were newly sealed-up when put into the vinery, eighteen days afterwards ate themselves out of the cells, many just able to get the head out, and many of the young eggs remained a week without any apparent change on them. When there are bees to attend—even a few—they will still be able to keep the brood alive unless in very severe cold.

I may state also that he never used any foreign honey for feeding—only sugar mixed with their own honey, and his treatment of bees has been the same as mine throughout in every respect. Perhaps I was more particular in giving mine always a new hive when they swarmed; while he sometimes put them into a hive which had been used, although never in a bad state.

I have endeavoured to give the history of my neighbour's troubles with foul brood, in the hope that it may induce others to look out for it in their own apiaries, and if possible discover the cause of the disease. He has no hopes that Mr. Woodbury will get his own apiary clean again until he clears out the whole and begins again with a clean stock, but will be glad, like us all, to hear that he has been able to make a cure.—ALEX. SHEARER, *Yester Gardens*.

VARNISH FOR RUSTIC GARDEN SEATS.—First wash the woodwork with soap and water, and when dry do it over, on a hot sunny day, with common boiled linseed oil; leave that to dry for a day or two, and then varnish it once or twice with what is commonly termed "hard varnish." If well done it will last for years, and will prevent any annoyance from insects.

OUR LETTER BOX.

AGRICULTURAL HALL, POULTRY SHOW.—Owing to the gross neglect of the London and North Western Railway Company, my birds were not delivered at the Agricultural Hall Poultry Show in time to be judged. Had they been duly delivered I feel assured they would have figured in the prize list, as they always have done. My annoyance can be imagined.—EDWARD TUDMAN, *24th Grove, St. Ratchurch, Salop.*

PRIZES AT THE SHEFFIELD SHOW.—Can any of the exhibitors at the last Sheffield Show, held at the Cremona Gardens, inform your readers if the prize money has been paid?—EMERSON.

LONDON MARKETS.—AUGUST 31.

POULTRY.

There is no trade, and the supply of poultry is large. We are yet unable to speak confidently about the supply of Grouse, but our impression at present is, that it is not a great breed in Scotland. The birds from the English moors are very good.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 68.3°, and its night temperature 46.1°. The greatest heat was 86°, on the 12th, 1858; and the lowest cold, 28°, on the 11th and 12th, 1860. The greatest fall of rain was 1.27 inch.

ROSES IN THE SUBURBS.

NE of the most unsatisfactory features of the usual communications upon Rose matters is the array of mere names; and another is the scanty details given of the individual flowers, so that

the uninitiated, whose information should be the primary consideration, are unable to realise an idea of them, or to judge whether they are likely to repay the trouble and expense of experiment. Bearing this in mind, I purpose in this paper to treat upon a few prominent favourites from a suburban's point of view. The results are those of actual practice and observation, which, however, may not always correspond with those of growers more favourably placed. I must premise that most kinds come relatively smaller with me than in the country. That, however, is scarcely a fault, for what they lose in size they gain in symmetry and compactness; indeed, the craving after mere bigness is the sore vice of the day. Not that size when combined with other recognised perfections is objectionable, but this union is not often found. I have seen stands this year in which, a day after the show, there was scarcely a Rose that did not display an eye like a buttercup, and that, too, in sorts that ought to be perfectly double if not overgrown.

The field of experiment, then, being a suburban locality, Madame Charles Wood and Charles Lefebvre appear to be, taken all in all, two of the best Roses out whether for the country or for town. The first is, perhaps, the freest bloomer, large here, at the nurseries monstrous almost, yet perfectly double and well-shaped. The colour is a brilliant light crimson, passing into deep rose; habit vigorous and free. Charles Lefebvre is a splendid Rose, large, well-formed, finely coloured; a deep crimson-scarlet, shaded with a purplish tinge in the centre; changes to a deeper tint when going off, but is still good, and stands atmospheric trials, perhaps, better than any other kind. Respecting this variety, I am disposed to believe, from its smooth varnished-like wood and leathery foliage, that there must be a touch of the Bourbon blood in it, and also in *Senateur Vaisse*. Both these kinds also bloom well in the autumn, which tends to confirm the opinion.

By the way, the *Senateur* has not done well with me this season. For general purposes *Jacqueminot* still continues the better. *Souvenir de Comte Cavour*, *Vicomte Vigier*, *Monte Christo*, *François Lacharme*, and *Triomphe de Caen* come next in order of success. *Souvenir de Comte Cavour* (Margottin's), is of a very rich velvety crimson, a very good grower and bloomer, form and colour of the highest merit. *Vicomte Vigier*, also

a vigorous grower and free bloomer in the purple-crimson or maroon line of colour, is a decided acquisition for suburban amateurs, who cannot succeed with *Louis XIV.*, *Arago*, *Patrizzi*, and the like. All of these have done worse in my hands this season than ever; and in spite of their beauty in congenial positions I have determined to discard them while I remain in these parts.

Monte Christo, dark crimson, imbricated form and moderate habit, is also good. *François Lacharme* is a fine, large, vigorous-growing Rose; colour clear red or bright carmine. In favourable soils it is perhaps the best flower of the season, though not over-free in bloom. We have, however, already others in much the same style quite as good, which is not the case as to *Madame C. Wood* and *Charles Lefebvre*, both of which are distinct. *Triomphe de Caen* is from the *Général* I imagine. It is a nice, bright, free-growing kind, but not quite the colour of a *Tom Thumb* *Geranium* as described by Mr. Rivers in remarks in section 2, H.P.'s, in his catalogue: nevertheless, it is worthy of a place in any extensive selection. *Madame Clemence Joigneaux*, a robust grower, somewhat after *Madame Donage*, or perhaps *d'Angleterre*, does well, but is by no means novel. *Louise Darzins* (is not this really a *Noisette*?) is a pretty white, small but symmetrical, and every way desirable for gardening purposes. We still are in want of a first-rate white H.P., and I do not believe any of the novelties for this season will supply the vacuum. *Alphonse Damazin*, scarlet-crimson, fine medium flowers in clusters, is to be recommended also. *Maréchal Vaillant* is a very free grower but shy as to bloom. Messrs. Wood & Son, of Maresfield, in their catalogue describe this as being a *Perpetual Paul Ricaut*, which, indeed, it much resembles. At present I am not certain about the behaviour of *Prince Camille de Rohan*, very dark. I fear it is one of the slender twiggy habit of growth, which never succeed here. *Turenne*, bright red, large, and flat, will do: there are, however, plenty of the kind better. *Nôtre Dame de Fourvières*, imbricated shape, pale pink, robust grower, almost spineless wood, is very distinct—a rare quality now-a-days, for I think rosarians will admit that one-half the varieties in the catalogues might be struck out and not missed.

I find these remarks extending to so much space that I must defer noticing older varieties, merely observing that *Due de Cazes* and *Colonel Cambriels* have done well this year. It will be observed that all previously noticed belong to last year's introductions, indicating that, as remarked by others as well as myself, to have been an unusually good season.

It must be borne in mind that it is a difficult undertaking to prove decisively the suitability of particular varieties to particular situations. Some plants do promisingly the first season after removal, yet never bloom or thrive again. There appears to be a reserve stock of vigour stored up in the plants themselves, especially when brought from first-rate soils, which carries them through the trials of a first season. If this stock of vigour is replenished by a strong and healthy growth

where they are removed to, the plants become established; but if not, they dwindle till they finally die. This may be especially seen with maiden plants from the nursery—indeed, there are some favourite exhibition sorts that never really bloom well except upon maiden plants. These may be called nurserymen's Roses. Madame Vidot is one of such. It is a great advantage that nurserymen possess as exhibitors over amateurs, that they have fresh plants every year to cut from for the shows.—W. D. PRIOR, *Homerton*.

THE CRYSTAL PALACE SHOW.

SEPTEMBER 1ST AND 2ND.

THE Exhibition on this occasion, though consisting of florists' flowers and fruit only, was magnificent, and of such extent that the tables on which it was arranged occupied nearly the entire length of the building, one half being filled with flowers, the other with fruit. The charge for admission being very low, and the weather on the first day very favourable, the attendance of visitors was large.

DAHLIAS constituted the principal feature in the floral display, Mr. Turner and Mr. Keynes, of Salisbury, taking the principal honours. The stand of forty-eight which Mr. Turner exhibited, and for which he received first prize, did not contain a single inferior flower—all were perfect. Madge Wildfire, Beauty of Hilpertown, Mrs. Trotter, Donald Beaton, Umpire, Hugh Miller, Criterion, Dinorah, Mr. Stocken, Cygnet, Sidney Herbert, Peri, Charlotte Dorling, Lord Derby, Mauve Queen, Mrs. Henshaw, Triomphe de Pecq, Andrew Dodds, Mrs. Vyse, Miss Pressley, and Mrs. Piggott were some of the finest. Mr. Keynes, who was second, had also an excellent stand, but some of the flowers were neither so large nor so perfect in outline as Mr. Turner's. Mr. Cattell, of Westham, was third; Mr. Walker, of Thame, fourth.

In twenty-four Mr. Turner was also first with Lord Derby, Andrew Dodds, Umpire, Hugh Miller, Lady Popham, Triomphe de Pecq, Earl of Shaftesbury, Mr. Stocken, Cygnet, Charlotte Dorling, Beauty of Hilpertown, Norfolk Hero, Lord Palmerston, General Jackson, Criterion, Lord Dundreary, Donald Beaton, Mrs. Henshaw, Midnight, Mrs. Vyse, George Elliott, Mauve Queen, Bob Ridley, and a seedling. Mr. Keynes was second with a stand scarcely inferior, in which were fine blooms of Lord Palmerston, Juno, Disraeli, John Wyatt, Lord Shaftesbury, Peri, John Keynes, Lilac Queen, Pauline, Mrs. Henshaw, Lord Derby, and Lord Russell. Messrs. Saltmarsh, of Chelmsford, had the third prize, some of their blooms—as Baron Taunton, Lord Derby, Andrew Dodds, Lilac Queen—being also very fine. Mr. Walker was fourth; Mr. Legge, of Edmonton, fifth; Mr. Barnes, of Danecroft Nurseries, sixth.

In the Amateurs' Classes the competing stands were very numerous, and there were but few blooms which could not be considered fine.

In twenty-four, Mr. Thornycroft, of Floore, near Weedon, was first—Volunteer, Juno, Peri, Criterion, Lollipop, John Dory, Lord Derby, Vestal, Mrs. H. Piggott, and Lord Palmerston, being the most remarkable. Mr. Sladden, of Ash, was second; Rev. C. Fellowes, Shottesham Rectory, third; Mr. Perry, of Castle Bromwich, fourth; Mr. Moffat, Easton Hall, fifth.

In twelve, Mr. Thornycroft was also first. His Volunteer, Lord Derby, Admiral Dundas, Criterion, and Beauty of Hilpertown, were all large and fine. Indeed the same might be said of the rest of the blooms he showed. Mr. Charlton, of Kilworth, was second; Mr. Sladden, third; Mr. Wakeman, Eltham Park, fourth; and several other very good stands were shown.

In twelve Fancies (Nurserymen), Mr. Turner had first prize for fine blooms of Pluto, Zebra, Garibaldi, Queen Mab, Rev. J. Dix, Countess of Shelburne, Harlequin, Summertide, Pauline, Lady Paxton, Mrs. C. Kean, and Fairy Queen. Mr. Keynes was second—Triomphe de Roubaix, Mrs. Wickham, Duchess of Kent, Leopard, Oliver Twist, Regularity (new), and Samuel Bartlett, also new, were the most remarkable. Mr. Legge was third, and an extra prize was given to Mr. Cattell.

In the Amateurs' Class, the Rev. C. Fellowes was first; Mr. Sladden, second; and Mr. Perry, third.

Several seedling Dahlias were also shown by Messrs.

Keynes, Legge, Bragg, and others. The first-named exhibitor receiving first-class certificates for Polly Fawcett, Edward Purchase, Samuel Bartlett, Fanny Purchase, and Anna Keynes. Mr. Collier, Bethnal Green, had a similar award for Princess Alexandra; and several second-class certificates were awarded to Mr. Keynes, Mr. Bragg, and Mr. Wheeler.

ASTERS, both German and French, were in the highest perfection. Those from Mr. Betteridge, Milton Hill, Stevenston, who had the first prizes in both classes, were beautiful examples of what careful selection and cultivation will achieve with this flower. In the German Quilled Class, Mr. Besley, of East Hundred, Berks, was second, and there were several other very meritorious collections. In the French Tasselled Class Mr. Betteridge was also first with large and beautiful blooms; Mr. Wyatt came next with blooms large, but not so regular; Mr. C. Sandford, third; and an extra prize was awarded to Messrs. Saltmarsh. Messrs. J. Chater, Ward, Jennings, Cattell, and Paul, had also good stands.

ROSES.—The display of these was not extensive, nor could it be expected to be so good as earlier in the season. The only exhibitors in the Class for thirty-six trusses were Messrs. Paul & Son, who had some good blooms of Louise Peyronny, Madame Rivers, Madame E. Verdier, and Lord Raglan. In twenty-four Messrs. Paul were also first, Mr. Turner second, and Mr. G. Clark, of Brixton, third, the latter having also a splendid box of Général Jacqueminot, the bright glowing red of which was very effective; and the same excellent variety was shown well in all the stands. Good examples of Sénateur Vaisse, Madame C. Crapelet, Souvenir de Comte Cavour, Gloire de Dijon, and Paire de Terre Noire were also shown.

Among Amateurs Mr. Exell, gardener to J. Hollingworth, Esq., of Maidstone, who has long figured as one of our most successful amateur growers, took the first prize. Pio Nono, Due de Rohan, Gloire de Santenay, Madame Bell, and Sénateur Vaisse were excellent. Mr. Dennis, of Folkington, was second; Mr. Moffat, gardener to Viscount Maynard, was fourth; good boxes also coming from Dr. Cooper, of Slough, and Mr. Pullinger.

HOLLYHOCKS.—Whether from the sun or in consequence of having been previously shown, some of these looked rather faded; still the blooms were of first-rate excellence. Mr. W. Chater had the first prize for twenty-four. Minerva, Governor-General, George Young, Lady Daeres, Warrior, Mrs. F. Mackenzie, Dame Blanche, James Allen, Princess of Wales, Cynthia, Princess, Joshua Clarke, and Matchless were all fine. Messrs. Downie, Laird, & Laing, who were second, had large and full blooms of Yellow Defiance, Pre-eminent, Countess of Craven, Purple Prince, Alexander Shearer, Lady Daeres, and Lord Loughborough. Mr. J. Chater, Gonville Nurseries, was third. His blooms were also very good, and well arranged for effect. In Messrs. Paul and Son's stand Black Knight was conspicuous for its dark colour, and Jules Margottin was a beautiful rosy crimson.

In the Amateurs' Class there were no blooms to equal those shown by the Rev. E. Hawke, of Willingham Rectory. Among them were David Foulis a white seedling, Purple Prince, Mrs. Cochrane, Premier, Prince Charlie (very pretty), Lord Loughborough, Queen Victoria, and Joshua Clarke. Mr. Flester, gardener to Mrs. Rush, Bishop Stortford, was second; Mr. Forrester, gardener to Mrs. Ogle, Beckenham, third; Mr. Small fourth.

VERBENAS.—There was a good display of these, Messrs. Perkins, of Coventry, being the principal prizetakers, and exhibiting L'Avenir de Bellant, Lord Leigh, General Simpson, and other kinds of established merit. Mr. Perry, of Castle Bromwich, who was awarded a second prize, had among others a seedling, the blooms of which were cupped, rosy crimson, with a pale yellow eye.

GLADIOLUS.—Of this flower, a splendid collection came from Messrs. Youell, of Great Yarmouth, among which the bright scarlet Brecheleyensis was conspicuous, and a first prize was awarded. Messrs. Youell, however, only came off second best in the class for the best collection, where Mr. Standish took the lead with Scottish Chief, Edith Dombain, Mrs. Dix, Impératrice Eugénie, Reindeer, and other new and striking varieties. Messrs. Youell had Mr. Youell, a bright vermilion and white seedling; Dr. Lindley, pale

rose flamed with carmine; Napoleon III.; Reine Victoria, white striped with violet and carmine; Impératrice Eugénie, and other first-rate sorts.

MISCELLANEOUS.—No prizes were offered for miscellaneous objects, and but few were produced. The beautiful *Lapageria rosea*, which stood at the end of the table where the flowers were displayed, cannot, however, be passed over. It came from Mr. Uzzell, gardener to the Dowager Duchess of Northumberland, and was truly a magnificent specimen of this splendid climber, being covered with a profusion of its rose-coloured flowers, and these of the largest size. Some double Zinnias from Mr. Banks, of Sholden, Deal, received an extra prize. Their colours were brilliant, and some gave promise that in course of time the flower would approach towards the *Chrysanthemum* in form, if not in size.

FRUIT.

The best collection of eight dishes came from Mr. Henderson, of Trentham. It consisted of an Enville Pine, Trentham Green-fleshed Melon, three bunches of Barbarossa Grapes, weighing 10 lbs. 11 ozs., large bunches of Canon Hall Muscat, Barrington Peach, Pitmaston Orange Nectarines, Moorpark Apricots, and Morello Cherries. Mr. Bailey, gardener to T. T. Drake, Esq., of Shardeloes, was second with a Providence Pine, Bailey's Green-fleshed Melon, Black Hamburg and Bowdow Muscat Grapes, Peaches, Nectarines, Plums, and Pears. Mr. Henderson had third prize for second collection; and an extra prize was given to Mr. Beale, of Wood Hall Park, for one containing an Otahite Pine of 7½ lbs. Collections were also sent by Messrs. Turnbull, of Blenheim; Young, of Havant; Spivey, Pragnell, Pottle, Pullinger, Young of Highgate, and Cross.

PINES were not numerous, but some were of very large size. A noble Queen of the immense weight of 7 lbs. 10 ozs., but not ripe, from Mr. Hall, gardener to Lord Scarborough, received a first prize. Mr. Young, gardener to C. Bailey, Esq., of Aberdare, had second for one weighing 5 lbs. 6 ozs.; and Mr. A. Grant, third, for a handsome fruit of 4 lbs. 14 ozs. Messrs. Page and Dwerrihouse had prizes in the Class for other varieties.

MELONS were extensively shown, the kinds being principally Golden Perfection, Orion, Trentham Hybrid, and Scarlet Gem. In the Green-fleshed Class, Mr. Scorer, gardener to C. Eyre, Esq., was first with a hybrid; Mr. Varney, second with Orion; and Mr. Turner, third with Marquis of Ailsa. In Scarlet-fleshed, Mr. Gadd, of Dorking, was first with Windsor Prize; and Mr. Whitaker, Crewe Hall, second with Scarlet Gem.

GRAPES constituted the most important feature of the display, and the fruit exhibited was of the highest merit.

Mr. Meredith, of Garston, was first in the Class for baskets of not less than 12 lbs., with Black Hamburg, splendid berries as black as sloes. Mr. Morris had also a first prize for the same kind, equally well ripened. Mr. Wortley, gardener to Admiral Cary, Norwood, was second for Canon Hall Muscat, of which the berries were of the largest size; and Mr. Harrison, Oatlands, Weybridge, had a like award for Muscat of Alexandria. Mr. Drummond, gardener to J. S. Smith, Esq., Tunbridge Wells, was third with Mill Hill Hamburg, the berries large and fine; and Mr. Henderson had an extra prize for Lady Downes'. Excellent baskets also came from Messrs. Monro, Solomon, Embrey, and Wills.

In the Class for the best three bunches of Black Grapes, Mr. Richards, of Grimstone Park, Tadcaster, was first with splendid evenly-grown bunches of Black Hamburg; Mr. Meredith, second with three weighing together 10 lbs. 13 ozs., the centre one alone being 5 lbs. 9 ozs. The berries, though not so regular in size as in the preceding, were well coloured. Mr. Drummond was third with Mill Hill Hamburg, the berries very large; and an extra prize was awarded to Mr. Henderson, of Trentham, for Lady Downes', fine. There were besides many other exhibitions well worthy of notice.

In White Grapes, Muscat of Alexandria, from Mr. Drummond, took first prize. These had the same beautiful amber tinge, betokening perfection of ripening, as the bunches from the same exhibitor which attracted so much attention at the Great Fruit Show of the Royal Horticultural Society in October of last year. Mr. Wills was second with Trebbiano, weighing 9½ lbs.; Mr. Turnbull, third with very fine bunches of Muscats, but not so ripe as Mr. Drummond's. Mr. Mere-

dith took the first prize for the largest bunch of any kind with Trebbiano, an enormous bunch of 5 lbs.; Mr. Goldsmith, Dorking, was second with Barbarossa, weighing 5 lbs. 14 ozs.; and Mr. Henderson, third with Marchioness of Hastings, 4 lbs. 7 ozs.

PEACHES.—Of these the exhibitions were very numerous, Noblesse, Royal George, Violette Hâtive, Bellegarde, and Walburton Admirable, being the kinds chiefly shown. Mr. Kaile was first with Barrington, very fine; Mr. Cross, gardener to Lord Ashburton, had a second prize for the same kind; and Mr. Dawson took a similar prize for Violette Hâtive; Vanguard, from Mr. Plester, came in third.

NECTARINES.—Of these Pitmaston Orange, Newington, Downton, Elruge, and Hunt's Tawny were the kinds principally exhibited, and most of the dishes were excellent. Mr. Ferguson was first with Pitmaston Orange; and Mr. Henderson second with Elruge.

FIGS were poorly represented as regards numbers. Brown Turkey, White Marselles, and Brunswick were the kinds shown. Mr. Eman, gardener to Miss Trotter, Epsom, was first; Mr. Wyatt, of the same place, second; and Mr. Turner third.

CHERRIES.—Some very fine Morellos were shown. Mr. Bailey, of Shardeloes, was first with that kind and Bigarreau; Mr. Dawson second with Morello and Florence; Messrs. Lane third with Morello and Bigarreau.

PLUMS.—The competition in these was very close, and the competitors numerous. The varieties principally shown were Green Gage, Kirke's, Washington, Jefferson, Goliath, Denyer's Victoria, and Yellow Magnum Bonum. Mr. Bailey had first prize for Washington, Sir C. Napier, and Prince of Wales; Mr. Pomfret, Eton College, second for Washington, Kirke's apparently, but unnamed as all the rest were, and Denyer's Victoria. E. Webb, Esq., of Reading, was third with fine examples of Washington, Yellow Magnum Bonum, and Goliath. Pond's Seedling from Mr. Grover and Mr. Gale, of Hammersmith, was very large.

APPLES, both dessert and kitchen, were shown in good perfection for the time of year, and the competitors were numerous. Mr. Pomfret was first with Cox's Orange, Red Astrachan (large and beautifully coloured), Ribston Pippin, Cox's Pomona, Peach Apple, and Whorle Pippin. Dr. Cooper, of Slough, was second with Devonshire Quarrenden, Cox's Orange Pippin, Cox's Pomona, Blenheim Pippin, Ribston Pippin, and Cellini.

In kitchen Apples Mr. Mortimore, Carshalton, was first, Mr. Vickary second, and Messrs. Lane third. Some excellent examples of Tower of Glammis, French Codlin, Blenheim Pippin, Hawthornden, London Pippin, Dumelow's Seedling, and Kentish Fill-Basket were exhibited.

PEARS.—Williams' Bon Chrétien was the kind principally shown, but there were also some good Marie Louise, and Louise Bonne of Jersey. Mr. Harrison, of Weybridge, was first, in three dishes; Mr. Nicholls, Hammersmith, second; and Mr. Donald, Leyton, third. There was a Class in which weight was to be the point of merit. A dish of Uvedale's St. Germain weighing 10½ lbs. was first; Grosse Calebasse, from Mr. Dwerrihouse, was second; but in this instance, as in most others, the weight was not stated.

MISCELLANEOUS.—A collection of Pines, Apples, Pears, Plums, Figs, and Vines in pots, from Messrs. Fraser, had first prize. Mr. Henderson, of Trentham, was second, for some large Moorpark Apricots. Mr. Webb, of Reading, had a collection of eight kinds of Nuts, among which Webb's Emperor and Prize Cob were very large. Some excellent Red and White Dutch Currants were shown by Mr. Gregory, Clarendon; *Physalis edulis*, by Mr. Pottle and Mr. Marsham; and Hall's Volunteer and Telegraph Cucumbers by Mr. Hall, of Colchester.

SHOWS AT THE AGRICULTURAL HALL, ISLINGTON.—It may be interesting to our readers to know, that at the recent Show held in the above Hall, a meeting of the exhibitors was convened in order to ascertain their views as to the advisability of holding periodical shows of fruit, flowers, &c., at the above Hall. It was agreed to by all present that at least two might be held annually. From a want of knowledge as to what date other Societies would hold their Meetings in the ensuing summer nothing could be decided

upon for the present. It was agreed, however, that at an early date a Committee should be formed to fix the dates and make up a schedule, which, from the liberality of the active Manager's suggestions, we doubt not will contrast favourably, as regards amount of prizes, with some of the schedules of leading Societies.

NOTES ON GARDENS PUBLIC AND PRIVATE.

NO. 4.—LORD LECONFIELD'S, PETWORTH HOUSE, SUSSEX.

WITH strange feelings one revisits the scenes of boyish days; and how wisely ordered is it that, in looking back, all the disagreeables connected with the past vanish away, and one only recalls those days which in modern parlance would be called "jolly!" Here was I within a few miles of my former school-place—Medhurst. There flowed the Rother, in which I had had many a plunge; in the Park were the noble Chestnut trees, off which some of "ours" who had connections in Petworth used to levy toll; and vividly came before one all the happy hours of one's boyish days. I did just think of the many times when, instead of enjoying a quiet dip, one of the big boys would take me by the nape and one leg, and pitch me into a hole some 10 feet deep, where another was waiting to receive me; and then one recollected that terrible work it was to get up early and have to clean my "master's" boots and shoes, or to fig out at cricket, and such little disadvantages. But, after all, these left a very faint line in one's recollection, like those of whom we read—that they forgot soon all their hard servitude, but remembered the "fruit that they did eat in Egypt freely, the Cucumbers, and the Melons, and the Leeks, and the Onions, and the Garlic." But one's views had quite changed: flowers which then would have been nowhere compared with a game of cricket or three-hole-span, were now the ruling powers; and to visit the gardens of Lord Leconfield one object which I had proposed to myself in my short visit to my friends at Petworth; and of some of the most notable things it is my desire to give a brief record.

I found, as I have invariably found to be the rule, that on telling the object of my visit every information is most readily and cheerfully given; and Mr. Jones, the able and intelligent gardener, on whose shoulders no small amount of responsibility rests, was kind enough to go with me over the gardens and grounds, and I only regretted that the shortness of my visit prevented me from gaining much and valuable information in the various departments of horticulture. The extent of walled-in garden ground which Mr. Jones has under his care amounts to fourteen acres; and some idea of the work that this involves may be gathered from the fact that he has two miles and a half of nailing to get through! Now one does expect in a royal establishment like Frogmore to find things done on a large scale; but this conveys to my mind a wondrous notion of the princely manner in which our great magnates of the aristocracy live on their estates. Nor is Lord Leconfield one of those who think that work is to be done without hands. He employs liberally, and allows Mr. Jones to feel that he is not required to have work done any way. Thus, while I believe at Frogmore, where (owing, doubtless, to parliamentary revision looming in the background), one man is allowed to an acre, here twenty men are allowed for the fourteen acres, besides whatever additional help may be needed—and surely this is the wisest plan and truest economy. As a consequence everything was in excellent order, and signs of progress visible on every side. The range of houses is not extensive, many of the old ones having disappeared, and new ones not yet having supplied their place; but some are being built, and the most is made both of the houses and ranges of pits and frames which the garden contains; for it is in fruit and vegetables that the glory of this establishment consists, for, save one long walk running down the centre of the garden, which has been most successfully managed, there is no attempt at a flower garden. Would that I had the ear of his lordship, and I would most assuredly ask whether something might not be done to give a more ornamental character to the place. With such a park I can quite understand that a nobleman might wish to have the noble herds that adorn the park coming close up to the windows of the mansion; but surely the view

would be none the worse for having a brilliant parterre between them and it. At any rate, in some place or other I should like to see a gardener of Mr. Jones's evident skill and taste having a scope for his talents, for I am sure the result would be worth looking at.

Fruit is managed here on a somewhat extensive scale. Thus, during last year there were cut in nine months 260 Melons. To effect this in by no means a large space, and to run it over so long a period of time, shows good gardening and management. The Pines were also in excellent condition, the Queen being that most in use; and as many as forty Pines weighing from 3½ to 4½ lbs. have been sent in at one time for preserving, and, of course, a tolerably constant supply for the ordinary use of the house is maintained. In the Peach-house the greater quantity of the fruit had been gathered, but there was still some left of excellent quality. Of this house Mr. Jones mentioned a curious fact—that when he was making the house ready it so happened that there was considerable delay, and that the trees were ready long before the house was—that he had to keep his trees out of doors under walls, moving them about from time to time—that they were not planted until they were in full bloom, and yet that he gathered 40 dozen of Peaches from that house the first season. This led on to the subject of orchard-houses; and I may just mention that Mr. Jones, who is a "thoroughly practical man," stated that he had carefully examined the subject, both on the score of economy and efficiency. He had determined to suggest to his employer the propriety of building a regular Peach-house in preference to an orchard-house, and that he had heard or seen nothing since to cause him to regret his determination. Grapes were, as might be supposed, excellent; and Spary's fumigator has been found to be of great service in preventing the progress of mildew—in fact, far superior to anything else. The very simple manner in which the pulling up and down of the sashes was managed struck me very forcibly—so much so that I have obtained a sketch of it, which I hope will shortly appear in *THE JOURNAL OF HORTICULTURE*.

Strawberries are grown extensively, and the soil suits them well. British Queens were still in bearing, while Keens' Seedling was just coming in. As forcing is extensively practised, the plan here is to use a large number of plants for this purpose, and when they have finished to turn them out in a carefully prepared quarter, to attend to them regularly in the matter of watering, &c., and to look confidently for the result: a good crop of Strawberries coming in immediately after the British Queens are over, and lasting on throughout August, thus effecting what none of the so-called late Strawberries do—a prolongation of the fruiting season. I dare say this may be a very ordinary method of procedure; but it was new to me, at any rate upon such a scale as practised here.

On the walls was, of course, to be found an immense quantity of fruit, although some of the trees were very old and exhibited evident symptoms of decay, some of the Pear trees bearing the mark of 1803 on them. Nor were humbler fruits neglected. There is an immense collection of Gooseberries comprising 150 sorts, many of them good, others having only their size to recommend them, and others absolutely worthless; while a bed of Cranberries, a fruit little known or appreciated in this country, furnishes an ample supply of a very nice ingredient for tarts, &c. The bed is 30 feet wide, and was in full vigour. I must not forget to mention a Fig tree in a house. It is of the Nerii variety, and is believed to be one of the oldest of the kind in England. From it last year Mr. Jones gathered 5000 fruit in September, and the last sent in was on January 7th.

Vegetables are cultivated on the same extensive scale as fruit, and present as striking features. Thus Dwarf Kidney Beans are obtainable every day in the year. They are sown, not in pots, but in pits, precisely as in the open ground; and a succession is sown every three weeks until the out-of-door crop can be used. Peas were here, as in most other places, suffering from mildew; but one sort particularly struck me, and Mr. Jones stated it to be one of the best Peas grown. It is called Carpenter's Express. A crop was sown on November 20, and was gathered from on May 7. Then, again, Cucumbers were excellently managed. They had been in bearing since the 7th of January; and Mr. Jones was now cutting back some of the plants with stems

an inch in diameter and quite woody, and from these a second and excellent crop will be obtained. The very best Lettuce that I have seen this summer was here, and only one kind is used—a hybrid of Mr. Jones's own raising; and when once introduced I question whether any other of the numberless varieties of Cos Lettuce (*Laitue romaine*), would be grown.

I have said that little can be said on the subject of flowers, but what is done is done well. The house plants were models of health, while the bedding-out displayed the hand of a master. Annuals of the commoner sorts—*Nemophila*, *Mignonette*, &c., are largely cultivated; for among Lord Leonfield's practices is one worthy of imitation by all our great landowners—viz., the encouragement of a taste for flowers. Every year Mr. Jones makes up five thousand packages of flower-seeds, which are on the annual rent day distributed to the tenants; three men being employed all day, as the tenants come out from the house, to give them. Imagine what labour this is; but also see in it a recognition of that truth one would so earnestly impress on others—that a love of flowers is ever desirable from the very lowest to the very highest. *Verbenas* have received somewhat of Mr. Jones's attention, and he has succeeded in raising one of a shade of maroon, which I think is likely to be useful as a bedding variety.

Something has been said lately in *THE JOURNAL OF HORTICULTURE* on the subject of trees, and the dimensions of some of them given. There were some remarkably fine trees in the demesne here, but I had only time to measure one, but that seemed to me a unique specimen—a *Tulip Tree* (*Liriodendron tulipifera*), which at 5 feet from the ground measured 17 feet in circumference.

Such, then, are a few rough notes on these well-managed gardens. Let it be borne in mind that they are not spick and span new, with all modern improvements in buildings, &c. No, they are quite the reverse of this; but they have an intelligent head and a liberal owner; and I have never seen an establishment which more thoroughly gave me the idea of clear sound sense in the administration, or liberality in the supply; and Mr. Jones may well be proud of the admirable efficiency in which each department of the garden is maintained.—D., Deal.

WHAT OTHER FLOWERS THINK OF IT.

"Ah! General Tom Thumb, how do you find yourself this fine, bright sunny morning? I see you are shaking the dewdrops from your flowers and leaves. These are dry times, and, doubtless, you think as I do, that the drops are more grateful at your feet than on your head."

"True, Miss Verbena. What you express I am sure we all feel. Some happy event must have taken place in the world, or in fairyland, for Nature's tears have fallen but sparingly this season, while her smiles have been abundant. We could do no less in acknowledgment than put on our gayest attire and look our best; but even this becomes in time oppressive."

"Really, General, you take an extensive view this morning. You surely do not allude to that event which set the whole community rejoicing while the year was yet young. In short, do you allude to the Royal wedding? if not, I can form no idea of what you mean."

"Well, may be I do, and perhaps I do not. I will leave you to form your own ideas of it. We had a grand company here yesterday, and probably you overheard some of the conversation as one party of ladies and gentlemen after another passed this way."

"I did, General, and felt highly flattered at the unusual compliments that were showered upon me and my sisters; and I also heard some very complimentary remarks directed towards yourself and your younger brothers—such, in fact, as are likely to keep up your spirits for the next two months in spite of the dry times."

"Ah! Miss Verbena, it is refreshing to hear oneself praised in such a manner. It repays one for a deal of suffering; and, in fact, something of the kind was needed in return for the amputation of one or two of my limbs. That, however, is over, and the wounds cicatrised. But of the conversation, I cordially agree with my Lord S., that such

bright and glowing masses of beautiful colours as we furnish for five months of the year are worth waiting the other seven for. And do you remember the words of Lady S., that the looking over a broad expanse of well-kept, smooth-shaven lawn, dotted about with fine shrubs, and relieved by beds of the choicest flowers, such as we furnish, was like transporting a mortal into fairyland, and far surpassed anything that ever could be imagined in the 'Arabian Nights'; in fact, that it was a most thoroughly enjoyable sight?"

"Yes, yes, I remember: and also as a group of ladies were casting admiring glances at us, one remarked that there was something so charming in the *Verbena*, so unassuming, and yet so engaging, that it would never fail to be a favourite flower. Of course, we could do no more than put on our sweetest smiles, and endeavour to look our best. It was the only return we could make."

"And that was and is all that is required of us. Rest assured, that in trying to do more we should only put ourselves in the position of the jackass which tried to please his master by jumping upon his lap and kicking his face. By the way, do you remember, Miss *Verbena*, when we were put out by the fence, preparatory to being bedded, if not wedded (excuse my boldness), do you remember overhearing a confab between Mr. *Hollyhook* and Miss *Rose*? Now, I have no objection to Mr. *Hollyhook* giving himself such airs, and nursing up the notion that he is a stately old flower. I quite agree that he is; but there was no necessity for him to run us down, and call us 'things of delicate constitution.' He himself has to bear his part in this fashionable style of planting and gardening; and if Mr. *Cuttings* has it all to himself, he comes in for his full share of neglect. But then it is not so, and he has found out how people's thoughts and ideas change with the season, as witness the numerous visitors we have."

"You are quite right, General. And then, again, as to the disparaging remarks of Miss *Rose*, in reference to her cousins, 'those lanky hybrids,' why the truth is, those hybrids are more thought of than ever she was. But, hark! I hear footsteps."—F. C.

SUCCESSFUL ORCHARD-HOUSE MANAGEMENT.

I HAVE just seen an orchard-house in excellent order, and full of fruit, at Littlegreen, near Petersfield. It is a lean-to, 15 yards by 6, and was built in 1861, when it was filled with Peach, Nectarine, and Plum trees from Mr. Rivers. There is an abundant crop of fruit on all the trees, and the only mistake in the management is that the fruit on some of the trees has not been sufficiently thinned. The fruit of those trees on which the number is not so great is very fine, and the flavour of all is first-rate.

There is also to be seen in these gardens a Peach-wall, facing east, not glazed, with a very good crop of Peaches. The trees are very healthy, with clean green foliage, without any signs of red spider, and their healthy condition seems to be owing to their having been syringed regularly two or three times a-week with soap-suds, mixed occasionally with sulphur.

The active and intelligent gardener told me that if he had not done this, the trees would have been eaten up by red spider; but as soon as he saw the first sign of red spider he began with the soap-suds, and never ceased till the fruit began to ripen. He has the reward of his care in the very satisfactory state of his trees. If all gardeners were equally wide awake, we should not see nor hear of so much red spider as we do.—PETERSFIELD.

THE GARDENERS' FRIENDLY SOCIETY.

I AM of the same opinion as Mr. D. Phelan and Mr. John Hague respecting this Society. I feel sure if it were once started it would be well supported.

I had previously filled up a form to become a member of another Society, but have laid it by till I see the result of this. I have already belonged to the Ancient Order of Foresters for upwards of seven years, and am pleased to say I have never taken anything from that Society; and if I

join this I hope I shall never want anything from it. I shall only be too pleased to contribute my mite to help others, and I hope all who join it will do so in the same spirit.—JAMES CLEWS, *Gardener, Cloone, Mohill, Co. Leitrim, Ireland.*

[We are able to state that steps are taken towards establishing the proposed Society; but it is still very desirable to have criticisms and communications upon the subject.—EDS. J. OF H.]

NOTES ON FRUITS RECEIVED.

WE have received several specimens of fruits of so unusual a character, and of varieties that are so little known in this country, that we take this opportunity of bringing them before the notice of our readers.

The first we received were from the Rev. Thomas Bréhaut, of Guernsey, well known as the author of an excellent practical treatise on the cordon system of training. Through the kindness of this gentleman we have been introduced to an acquaintance with two Peaches of American origin, of which we had previously heard, but of which we had not seen the fruit in this country. They are both varieties peculiar to the Southern States, and are, we believe, natives of Georgia.

STUMP THE WORLD is of large size. The specimen received was 9½ inches in circumference. The shape is roundish, rather inclining to roundish-oval, flattened and rather pitted at the apex; the suture shallow and passing a little beyond the apex. Skin pale yellowish-white, finely dotted with red, and with a good deal of colour next the sun. The flesh is white, very melting and juicy, rich, and deliciously flavoured. This is a fine Peach.

EXQUISITE belongs to the class of yellow or Apricot Peaches, and is also of very large size, as large as the preceding, but is terminated at the apex by a rather prominent and sharp nipple. The flesh is yellow, and in the specimen received it was rich and highly flavoured—quite equal in condition to what we once, and only once, tasted in Crawford's Early, to which this variety is nearly related.

These two varieties were grown in an orchard-house without heat, and on very small trees, which produced seven and four fruit each. This is, doubtless, the first occasion on which these varieties have fruited in England.

From George F. Wilson, Esq., of Gishurst Cottage, Weybridge Heath, we have also received some very fine specimens of successful orchard-house cultivation. We can hardly say we were astonished to see the specimens that gentleman forwarded, because we have on former occasions seen and remarked upon the produce of the Gishurst orchard-houses, and it has invariably been of a kind that excelled anything we have seen produced from any other quarter. The fruit we now allude to is a dish of Louise Bonne of Jersey Pears, and one of Transparent Gage Plums. The former are decidedly the finest specimens of the kind we have seen. Beautiful as that variety usually is, these are unusually so. The largest was 4½ inches long, and 3 in diameter; the skin highly coloured, and speckled like a trout. The Transparent Gage Plums were of a fine opaline appearance, and dotted with crimson just enough to suggest the similitude to the opal's fiery lustre. The skin and flesh were quite transparent, and the latter delicious in flavour.

Mr. Edward Pierce, of Yeovil, sent a basket of very handsome Nectarines called the **CRICKETT NECTARINE**, from having been raised at Crickett Park, near Crewkerne. The fruit is large, and in appearance like a large *Violette Hâtive*, but it differs from that variety in having large flowers; and the tree is so hardy, that Mr. Pierce informs us that for the last two seasons, when all the Nectarine-buds in his nurseries have been killed, those of the Crickett Nectarine have withstood the frost. The flesh of the Crickett Nectarine is rich, and of a very fine flavour. Like the *Violette Hâtive*, it is quite red at the stone.

From Mr. Rivers, of Sawbridgeworth, we have received several new varieties, some of which never produced fruit before this season. They were all grown in the orchard-houses in Mr. Rivers' nurseries.

SEEDLING NOBLESSE PEACH.—The remarkable character of this variety is that it has round glands on the leaves.

The fruit is medium-sized, roundish, and marked with a shallow suture. Skin covered with a fine down and perfectly pale, except with a very faint trace of colour on the side next the sun, amounting to only clusters of a few dots. The flesh is white, quite pale at the stone, with sometimes the faintest streak of red, but not a tinge, and separating freely from the stone. It is quite white or greenish-white, very tender and juicy. Juice abundant, very richly and deliciously flavoured. A first-rate Peach.

GOLDEN RARERPE PEACH.—This is one of the yellow-fleshed Peaches. It is of very large size, roundish shape, and marked with a deep suture. The skin is pale orange on the shaded side, with a considerable blush of red on the side next the sun. The flesh is deep yellow, and considerably tinged with red at the stone, from which it separates freely. It is very tender and juicy, but with rather too brisk a flavour to be considered desirable. It is a large handsome-looking Peach. The leaves have kidney-shaped glands.

SEEDLING PEACH 5, from White Nectarine.—A large and handsome Peach, round, and with a deep suture. The skin is perfectly white, and has not the least trace of colour upon it. The flesh is also perfectly white even to the stone, from which it separates very freely, not very juicy, and the juice cold, acid, and rather bitter. Glands reniform.

CANARY PEACH.—A fine, large, pale straw-coloured Peach, 2½ inches in diameter, and terminated at the apex with a sharp-pointed nipple. The suture is distinct. The skin is uniformly of a very pale warm yellow or orange, and without any trace of red—indeed it may well be called Canary. The stalk-hole is deep and wide. Flesh separating from the stone; pale orange, very tender and melting. Juice very abundant, sweet and rich, with a delicious, fine, and racy flavour. Leaves without glands. A large, handsome, and most delicious Peach. A first-rate variety.

MONSTRUEUSE DE DOUÉ.—A noble fruit, 9½ inches in diameter, round, and with a suture that passes round the whole surface of the fruit. Skin pale green, mottled all over with thick dottings of red, and with a red cheek where fully exposed to the sun. Flesh green, very deep red round the stone, from which it separates. It is rather firm, solid, and heavy. Juice very abundant, very sprightly, piquant, and racy. A splendid Peach. As a fine market variety this will be invaluable.

HONEY PEACH from China.—A curious ovate-shaped Peach of medium size, terminating at the apex in a sharp long nipple, and marked with a faint suture. The skin, which is covered with a very fine down, is perfectly white, and has no trace of colour on it. The flesh is perfectly white, with just a faint trace of red round the stone, from which it separates freely. It is very tender, melting, and juicy. Juice abundant, quite sweet and delicious, almost like a syrup. A very rich and delicious Peach, quite novel in character, both in appearance and in flavour. The leaves are without glands, and remarkable as being widely dentate. This is a very distinct variety.

TURENNE AMÉLIOREÉ.—A good-sized Peach, about 2½ inches in diameter, roundish, and a good deal hammered and irregular in its outline. Skin deeply mottled and clouded with dark crimson almost over two-thirds of the surface, and pale yellow on the shaded side. The suture is merely a faint line, and not deeply marked. Flesh yellow, deep red at the stone, coarse, acid, and bitter. Separates with difficulty, and is not at all a desirable variety. Leaves without glands.

CRIMSON MIGNONNE.—Fruit about medium size, roundish, and rather uneven in its outline, marked with a very faint suture, and pitted at the apex. Skin almost entirely covered with very dark crimson, almost black, as much so as the *Bellegarde*. The little on the shaded side that is not coloured is a pale yellow. Flesh very tender and melting, very much and very deeply stained with blood red at the stone, from which it separates freely. Juice very abundant, rich, sprightly, and deliciously flavoured. This is a very distinct and very excellent Peach. Glands round.

CYANOPHYLLUM MAGNIFICUM.—I have the *Cyanophyllum magnificum* with leaves 25½ inches in length, and 14½ inches in breadth.—STARKIE BALDWIN, *Gardener to John Moore, Esq., Palace House, near Burnley.*

GLADIOLUS DISEASE.

In your Number of August 11th you mention a disease similar to the Potato disease having attacked the Gladiolus near London, and request information as to those grown in the country. Having grown Gladioli for the last twelve or fourteen years from bulbs, not seed, I can fairly answer your question, and state that this year is decidedly the worst I have known.

Perhaps owing to last year's rain our bulbs were not harvested in the best condition, and they were not so robust as usual; but the bulbs this year seem to suffer from two diseases. In one case the old bulb hardly makes any roots, remains very dry, and consequently only forms a small and weakly new bulb, which throws up its head until the flower-spike is on the point of blossoming. It then turns yellow, withers, and dies. In the other case the old bulb rots away entirely, leaving only a weakly new bulb, or perhaps none at all.

I planted my Gladioli this year in three large beds, one manured with rotten dung, one with well-rotted hops, and the other had no manure at all. That manured with hops turned out the best, and I have to thank Mr. Youell for the hint. The other two beds were very bad—perhaps the one not manured was the worst.

The disease is not confined to Gladioli in beds, as I have about twelve lots of seedlings in pots and boxes. Some of these have also gone off; others, last year's seedlings, have blossomed.

I should be inclined to grow Gladioli in peat mould if I could procure it more easily, and to manure only with rotted hops, as some *Brenchleyensis* we have in a peat border are very healthy; but, from having been planted there three years running, have sported their colours.

Can anybody recommend me a good yellow Gladiolus? I have raised many from Ophir; but they are not pure yellow, generally yellow with lilac.—FRED. B. HANKEY, *Capt., R.N., Fitcham Park, Leatherhead.*

EARLY RIPENING OF MUSCAT GRAPES.

I READ with very great pleasure the account Mr. Thomson gave of his Muscat, and hoped it would have opened a discussion; but as it has not done so, I venture to ask, Has any one found that when the Muscat of Alexandria is grown in bottom heat it sets as well and is not a week behind the Hamburgs?

The time required to mature a crop depends on the heat used, and, with Vines planted outside, on the time of the year. If, then, we place our Muscats in a situation unsuited to them, should we call them late? I think we should say simply, that they are more tender, and that if they have a warm soil with the same top heat as is used for Hamburgs, they may be ripened in twenty weeks.

If some one who has had more experience would give a little information on this subject, I, for one, should be very much obliged.—G. H.

[Whatever may have been the cause of the unusual earliness of the Muscat, which has ripened so long before the other varieties here (Archerfield) for the last three years, it cannot, so far as I can trace the matter, be attributed to any extra bottom heat which has not been enjoyed by the other Muscats in the same house. And in testing it against the Black Hamburg this season it laboured at a considerable disadvantage on the score of bottom heat, in so far as its roots were in a cold, open house, while it was being forced in another vinery along with the Hamburgs, to which bottom heat was applied by fermenting material on the surface of the border. It is not necessary to detail this trial of the Muscat against the Hamburgs, as it can be referred to in the Number of the Journal in which I minutely detailed the whole circumstances.

There are other two matters that strengthen my conviction that the earliness of the Vine was not caused by extra bottom heat. The one was the fact that the Vine was always a weakly grower, which is a result, as far as my experience goes, exactly the reverse of that which is produced by bottom heat. I have found that Vines always grew more quickly and stronger with bottom heat than

without it. The other is, that a Tynningham Muscat, which ripens earlier than the old Muscat, is planted within less than 2 feet of this early Vine, and I cannot well conceive how the roots of the one could have more heat than the other.

The border is so far heated from beneath that I have taken the advantage of a pipe which passes through the middle of the border to another vinery, and have confined the heat from that pipe, and given it every means of disseminating among the open rubble with which the border is amply drained. The whole of the Muscats in this vinery ripen earlier than any that I have ever previously seen, and this I attribute to the bottom heat in conjunction with a lighter soil than Grapes are generally grown in; and I quite agree with your correspondent, "G. H.," that with the aid of bottom heat and the use of a light soil, Muscats can be ripened much earlier than is general, for I have proved the fact—and, more than this, that they can be brought to a pitch of ripeness that is scarcely attainable when they are grown in cold borders and in heavier soils. But this does not account for the disparity between a particular Vine in the same border with others.

Our early Muscat-house, which is the one now referred to, having bottom heat in the border, was started with fire heat on the 20th of January, and the Grapes were quite fit for table the first week in June, which is under twenty weeks, and those weeks by no means the warmest weeks of the year. Now, the difficulty of ripening Muscats thoroughly at a much more advanced season of the year has been yearly demonstrated at the various shows where this Grape has been competed for, and even up to September the complaint of reporters has been that Muscats have been unripe, however large and fine may have been the bunches and berries. In fact, the larger the bunch and the berries, the greater the difficulty of producing at an early season that degree of ripeness with that pitch of amber colour which is both the certain sign of high flavour, and the most essential condition to hanging long in a sound, unshrivelled condition.

There is no doubt whatever that Muscats can be grown into much stronger Vines, that will yield larger bunches, and swell much larger berries when planted in borders composed of a heavy, somewhat tenacious loam, as compared with the produce of lighter soils. In the one case there are produced stronger wood, larger leaves, with fruit and everything on a more gigantic scale, and very pleasing to look at. But just as these conditions are produced, in the same degree is the season of ripening the crop lengthened out, more particularly if the bed of soil in which they are growing is deep, and not very particularly drained. On the other hand, a light, sandy loam not over liberally enriched with vegetable matter, such as dung or leaf mould, produces a Vine of less strength, having smaller foliage and bunches, and berries small in proportion; but the fruit will ripen on such a soil long before that produced under the reverse circumstances which have been described. The fruit will also attain that transparent amber colour tinged with those russet spots which characterise the highest pitch of ripeness, and which is accompanied with that rich Muscat flavour which is present only to a very faint extent in indifferently-ripened fruit.

A light soil, in conjunction with bottom heat, always ripens Grapes earlier than a heavier cold soil; and what might be expected to produce the best Muscats in all respects is a somewhat tenacious loam thoroughly well drained, and efficiently heated from beneath with hot-water pipes. Under the latter conditions there would be little difficulty in ripening them thoroughly in a shorter time than when no bottom heat is applied. But for quick work in securing a well-coloured crop of Muscats, a lighter soil is preferable, although the fruit will not be so large as that produced on the stronger soil.

From recent observations, I am convinced that the border should become something like what might be termed very dry as the ripening process goes on, and that not a drop of moisture should be allowed to fall on the border after the fruit begins to change colour. One of the changes which go on in fruits during the ripening process is the dissipation or decomposition of the water which they attract; and the less of this element there is present to decompose, the more is the ripening process accelerated, and the greater are the

chances of a more perfect state of ripeness; so, obviously, an excess of moisture will retard and prevent ripening, in consequence of the longer time required for its decomposition. To gorge the system of a plant which has its roots in a soil with a low temperature, must, more particularly under so dull a sky as we frequently experience in these latitudes, retard and prevent the ripening of so tender a fruit as the Muscat Grape. The most careful drainage, with the aid of bottom heat, is the foundation for well carrying out the ripening of this Grape, and the precaution of covering the border with glass should be taken, if possible, immediately the ripening process commences. Not the least important agent in the production of early ripeness is a circulation of dry warm air about both fruit and foliage; consequently neither the wood nor foliage should be allowed to become crowded. It is, however, very important to have a large proportion of foliage, but it is by far the best way of balancing this matter to leave a good few joints beyond the bunch instead of stopping at the first or second joint, and allowing the laterals to make two or three leaves, by which means a crowding of foliage is produced, the house darkened, and the chances of high colouring and speedy ripening are lessened. The foliage should just be sufficiently thick to prevent the direct rays of the sun from acting on the fruit.

These remarks, hastily thrown together, in answer to your correspondent, will, I hope, be the means of provoking some discussion on the early ripening of Muscats, the noblest of all our Grapes.—D. THOMSON.]

MANURE FOR FLOWER-BEDS.

"A SUBSCRIBER" having asked "Which is the best manure for a flower-bed on a dry sandy soil on a gravelly bottom?" this article is given, as the question is one deserving more attention than a mere short reply, and as it is not unlikely there may be many to whom the subject may be interesting, especially in seasons like that just passed, when a long period of dry weather sets in during the time of the growth of many of the plants that form the gayest features of the flower-garden. As a very dry season and a very dry shallow soil resting on a hungry sand or gravel are at variance with the welfare of most classes of vegetation, it need not be wondered at if some one asks, In what way can such a situation be improved?

Fortunately, the case is not without its remedies, neither are the means beyond the reach of those who are anxious to try to grow bedding plants of most of the best kinds now in fashion. At the same time, be it remembered, there are other plants whose well-being cannot be looked upon as certain in a soil of this kind, as, for instance, *Phlox Drummondii*, the *Alonsoa*, *Calceolaria* perhaps, and some others; while it is not unlikely that some plants will do better in a soil of this nature than in one of a more promising description, and with some judicious alteration many of our flower-gardening materials will do well. A few plain rules to guide the inexperienced in the management of such a place will be here pointed out.

In the first place, it will be necessary to consider the character of the district the garden is situated in.

In the west of England, and in some other situations in hilly localities, the amount of rainfall is about double that of similar places on the east coast. Now, as vegetation while in an active state exists, in a great measure, on moisture, warmed more or less into a proper growing medium, the light shallow soil of the rainy district will suffice to support vegetation there, when the same description of soil is unable to do so in the long droughts more common in the dryer districts. Witness, for instance, the character of the grass lands that a traveller will often meet with on leaving London by any of the great lines of rail passing from its northern or western sides, and supposing such journey to be in August in a dry season, the parched character of the grass lands for the first fifty miles or so will be very apparent, while after that a gradual approach to freshness will be visible, so that when one hundred miles are reached the aspect is quite changed, and in fifty miles more there seems almost a superabundance of herbage. Now, all this may be on lands of a like character, the difference being due to two causes—one, the less one, being the increased heat of the

more southerly situation, and the other and more important one being the less amount of rain by which the earth is refreshed. Taking, therefore, these two examples, let us see in what way the dry place can be made to suffer less from the drying nature of its climate, and possibly a better state of things may be brought about.

Assuming the situation to be a dry one, and the soil of the flower-beds to be shallow, the first work to be done is to see if the soil can in any way be deepened. Trenching and removing a part of the unkind subsoil will be the most effectual way of doing this, adding, of course, the required quantity of better material to make up the necessary depth. Generally speaking, from 18 to 24 inches is not too much for a flower-bed that is expected to support a heavy crop of flowers all the summer. It is better to deepen the beds rather than raise them above the natural surface. It is also advisable to make the required addition with a stiffer soil than the one found on the surface, in order to retain the moisture somewhat better; for it must be remembered, that a dry gravelly bottom naturally sucks out what moisture the beds placed above it contain. It is, therefore, better as far as possible to prevent this, by adding some clay or other substance unwilling to part with its water; but a regularly puddled-bed, like one intended for a pond to hold water without leakage, is not by any means to be advised, a certain amount of drainage being necessary even for dry substances.

Another mode of benefiting a flower-bed on a dry soil is to add enriching manure, so as to feed the plant by stimulants instead of supporting it by a more steady and regular food. On this principle all plants in pots are maintained, and some do better in that way than when allowed more freedom; but they are the exception, and for the general purposes of cultivation it is a sort of hand-to-mouth system of cultivation, any neglect of supplying the plant with its required food at the right time being attended with bad consequences. However, manuring a plot of dry, sandy, or gravelly ground, is a more durable improvement than merely pouring water upon a potted plant, and it is often done with much advantage to the plant cultivated; and certainly is so with flowers of most of the favourite kinds cultivated in the beds of the fashionable parterre, some of them only requiring a sufficiency of nourishment to carry on the growth for a short period, and they flower all the better by a check being given to their luxuriance. Such, in fact, are most of the kinds of *Geraniums* of the *Scarlet* and similar breeds. But as a certain amount of growth is wanted in these as well as others, some stimulating substance is wanted when the ground is dry, and the depth of soil limited; and as the inquirer above alluded to asks what kind of manure is most wanted in such a soil, we may at once address ourselves to this part of the question.

Taking it for granted that the flower-beds formed on a shallow sandy soil on a gravelly bottom were planted at the proper time, and that the showers which followed in June not only kept the plants alive but encouraged a healthy vigorous growth which has continued until the setting-in of dry weather, a check has been given, and, no further growth taking place, the flowering of some such as *Calceolarias* threatens soon to be at an end. Now the only way to arrest such a premature decay is to supply the ground with liquid manure, not too rich at first, but increasing as the requirements of the plants seem to demand. Observe, I by no means advise a too liberal supply of the rich substance of the farmyard tank or a too strong infusion of guano; but, as the plant seems to occupy the space allotted to it so completely, some additional enriching substance may be given to maintain it in health. Of the kinds of manure water there is much difference of opinion; but the one most disagreeable to deal with is certainly the best in many cases. It must, however, be properly diluted, and its effects will be the more apparent; but all kinds may be used in moderation. The frequent use of clean soft water is also beneficial; and, in fact, whenever manure water is given let this all-important liquid in its pure state succeed it for several times ere the other is repeated. Dahlias, Roses, and the like may be treated to a few doses of this kind and be found the better of them.

With regard to solid manures applied to flower-beds much may be said. Generally speaking, these substances can only

be given in winter when the beds are empty, when farmyard manure may be applied tolerably freely; and we have found this the best kind we have ever tried for Geranium Golden Chain. In places, however, where this rather bulky manure cannot always be applied, a dressing of guano may be of service, or an application of bone manure, wood ashes, or soot; and we have seen much good done by an application of salt to a dry soil of the kind in question. In fact, those manures which in reality are composed of the necessary ingredients that will support the healthy existence of the plants to be cultivated are the kinds to be made use of; and as some of these contain the necessary quantities in a concentrated form, it follows that they may be used with less trouble than the others; but their use in a highly concentrated condition is not to be recommended, for the like reason that the strongest overproof spirits are unfit to be drunk. It is, therefore, advisable in most cases where convenient to give the preference to quantity. Manures, however, in less quantities must not be despised; and, though we have not tried all the kinds now in the market, we may say that guano of one or two kinds is good, as likewise is a sort of blood manure, bone dust, or rather crushed bones, wood ashes, and the charred burnt stuff of the rubbish-heap which contains as much burnt earth as burnt wood. All these and many other manures are good in their way, and so is lime when the soil is stiff and requires it, and for once it is useful on a dry soil; and, as all or most of the above can be given to the plants when in a growing state, by scattering them over the ground and slightly working them in, there is no difficulty in their application. Perhaps the most convenient of all for the above purpose are wood ashes, soot, and guano.

It may be here mentioned that a very useful way of preserving flower-beds from the effects of drought, and also of benefiting them, is to cover them with short dung—such, for instance, as is often gathered up by children on the public roads. This substance, short and not unsightly, may be spread on the bed between the plants, and it will to a certain extent prevent the evaporation of moisture from it, while the first rain washes its fertilising properties into the soil. Mr. Fish uses the old dung from his Mushroom-beds for a like purpose, and I have no doubt with a like beneficial result. The object aimed at is not to prevent the proper warming of the ground by the sun's rays, but to arrest excessive evaporation, which robs the ground of that moisture the crops so much require, and which it is the interest of all good cultivators to retain in time of drought. At another time it may be parted with advantageously; but when the soil available to the roots of plants becomes fully occupied, which it is when closely cropped, it then becomes necessary to husband all its resources, and nothing conduces more to this than preserving its moisture, and, at the same time, giving it more when its wants are so urgent as to call for artificial help.—J. ROBSON.

GARDENS IN GREAT BRITAIN.

I AM glad you have commenced giving a list of the best gardens in the kingdom, and hope your purpose will be ably seconded by those of your correspondents who reside in the different localities. I herewith add my mite to the collection in the form you have adopted at page 9 of the current volume; and as the present month is one in which gardeners are less busily engaged at home than in the earlier summer months, it not unusually happens that those possessing the means take a trip in some direction to see what is doing in other counties. In such cases the lists you purpose giving will be of great service to those not acquainted with the topography of these counties.

In mentioning the gardens recorded below I by no means assert that they are all the best the respective counties contain; but they are such as are worth visiting and such as I am acquainted with. Possibly there may be many others in the respective neighbourhoods equally good, and some better; but, not being acquainted with them, I must leave them for others to report upon. Your remarks on the propriety of admitting gardeners to visit gardens at all times are very good, and I hope you will urge on the employers of gardeners the propriety of providing their gardeners with

the means of visiting other gardens than those in their own immediate neighbourhood. They will in the end be the gainers by such a prudent outlay, for their servant will come home a better and a wiser man. As August is perhaps the least busy of all the summer months, the plan for the journey ought to be laid at once, and its results duly recorded. Subjoined I give a list of some of the gardens I have visited, omitting those mentioned in your former article.—J. Y.

THE GREAT ALOE OF VERA CRUZ.—There is now in flower in one of the conservatories of the Oxford Botanic Garden an unusually fine plant of the Vera Cruz Aloe (*Agave lurida*). It has a flower-stem upwards of 20 feet in height, bearing on its numerous lateral branches many hundreds of pale green flowers, which, although not particularly showy, are of great rarity and interest. The only recorded instance of a plant of this species producing flowers in this country appears to be that which flowered in the Royal Gardens, Kew, in the summer of 1811, and was figured in the "Botanical Magazine," t. 1522. The plant in bloom is of about eighty years' growth, thus going far towards verifying the frequent assertion that plants of this genus (*Agave*), flower but once in a century. This idea is, however, more espe-

Certainly they must never be trusted to railway officials or any person who does not know or care for the contents of the box. If only to be conveyed for a short distance, the safest way to do it is to put the box on a man's head and let him walk steadily, or, of course, it can be carried between two men the same as a basket is usually carried.

To send Grapes by rail or any other mode of transit without a person specially entrusted with them and yet preserve the bloom, is an almost hopeless task, and a different system of packing must be resorted to. The best plan that we have tried is to put a layer of paper-shavings in the bottom of the box, then a layer of wadding, then a sheet of tissue paper, on which the bunches are laid. They are then carefully covered over with tissue-paper, wadding, and paper-shavings, the same as that which is placed under them. There must be as much of these materials placed over them as will rest firmly on the bunches when the lid is screwed down, so that all motion of the bunch or berry is prevented. Each bunch should have a compartment in the box for itself, or at most no more than two bunches should be packed in one compartment. Grapes can be sent to any distance in this way, but not without rubbing-off the bloom to a considerable extent. If conveyed by the former method all that is required when the show table is reached is to take out the paper-covered tray of wood which we have described and place it on the table. In the latter case the bunches must, of course, be removed from the box and dished afresh. —D. THOMSON.

WELL HEAD GARDENS, HALIFAX, YORKSHIRE.

FEW persons entertain an opinion that there is any gardening worth seeing in or around our great seats of manufacturing industry. Our trees are represented as hidebound and incapable of expanding because of the smoke, and our gardens as containing nothing worth going a mile to see. Speaking for myself, I may say I have been in the valleys, by the side of the brooks, on rocks, in caves, passed from dells to hills, and from the mountain-top scanned Nature in all her loveliness, and seen her adorned in all those localities; but in no place nor position has it fallen to my lot to see her better assisted, nor her beauties stand out more nobly in the limited area of a suburban residence, than at the Well Head Gardens belonging to J. Waterhouse, Esq.

Well Head is situated about a mile from Halifax Station, about half a mile from the centre of the town. The gardens are enclosed by a rather high wall and are open to the south, towards which the ground slopes gradually, but still has an undulating surface.

I will enter this enclosure with my friend Mr. Baynes, the clever gardener, presuming that the reader may do so at any time if he feels disposed. Here I will observe, too, that the first objects I notice on entering a garden are the walks, the disposition of the ground, and the variedness of the arrangement. The walks here are formed of asphalt and spar, and are so smooth as not to cause any annoyance even to the feet of an invalid, but not so smooth as to be slippery. The ground is advantageously disposed, and the whole so arranged that but one feature can be seen at a time—in fact, it is just the sort of place where every corner brings you to a halt. It is a place where the alpine finds a home, the herbaceous plant a nest, and exotics find a comfortable resting-place.

We had scarcely entered the gardens before we met the proprietor, who is not only a man of science, but free, liberal, and kindhearted. Mr. Waterhouse gave one of the best reasons for the failure of Apricots in some localities that I have yet heard. It was simply this—"the soil is unsuited to their growth, and that success in Apricot-culture is more dependant on the geological strata than on the skill of cultivators. Where an Apricot thrives, fruiting profusely every year, a Rhododendron does not luxuriate. Lime in some shape is one of the components essentially necessary for the Apricot tree, but in what way it acts is as yet unknown. All, or nearly all, artificial soils made for Apricots fail to remove the predisposition of the tree to gumming or cankering, and no one, except those having the soil in which the Apricot thrives naturally, has succeeded in obtaining fruit annually

in pots or planted-out in an artificial or natural climate. Rhododendrons will not thrive on limestone; but limestone, in some shape or other, is necessary for Apricots to succeed."

Passing some rockwork crowded with trailing and alpine plants, always more or less interesting, where plants of *Osmunda interrupta* and *regalis* were thriving out-doors, a Fern-house, 30 feet by 18, first engaged my attention. The house is furnished with stone shelves, which, owing to their porosity, are calculated to absorb water, and give it off when the atmosphere of the house becomes drier than the stones, and that assists in keeping up a moist atmosphere in which Ferns revel. Out of a large collection the names of a few may be given as being conspicuous amongst their neighbours. *Asplenium bifidum*, a capital dinner-table plant; *A. formosum*, growing about a foot high; *Acerophorus charophyllus*, with creeping stems and finely-divided fronds; *A. pulchellus*, *var.*, a fitting companion for *Pteris scaberula*; *Davallia polyantha*, with creeping stems like the rest of the genus, but having handsome rosy fronds whilst young; *Gymnogramma gracilis*, a fine variety; *G. pulchella*, more powdered than generally seen; *G. peruviana*, 3 feet across; *G. chrysophylla*, richly powdered, and deeper in colour than many varieties of this species, of which *G. chrysophylla aurea*, a stronger grower, is paler in colour; and the woolly-fronded *G. lanata*; *Lonchitis pubescens*, a scarce and handsome kind, with pinnae not unlike an oak leaf; *Pteris natalensis*, something in the way of a gigantic *Adiantum trapeziforme*, but with handsome pale green fronds; *G. lutea*, looking like a cross between *G. peruviana* and *G. chrysophylla*, with the habit of the last; *Litochrocia nobilis*, much in the way of *L. (Doryopteris) sagittifolia*, but with a white mark or blotch in the centre of the frond, which is about an inch wide at the setting-on of the frond with the stipes, and tapers off in proportion to the length of the frond, generally extending from the stipes to three-quarters the length of the frond; *Nothochlana nivea*, 1 foot 6 inches high and 2 feet across; *N. tomentosa*, *vestita*, &c., in fine condition; *Cheilanthes hirta* *Ellisiana*, 2 feet across; *C. viscosa*, and many more of this fine genus in robust health; *Cibotium barometz*, 8 feet high and 12 across, growing in a tub; *Blechnum corcovadense*, with a tree-like stem over a foot in height and a head 8 feet in diameter—the fronds of this variety being a beautiful bronzy pink whilst young, which is retained till nearly mature. *Brainea insignis*, rosy crimson fronds when young, with wavy divisions—an exceedingly handsome variety from Hong-Kong, has a massy tree-like stem—the plant was 4 feet across; *Lastrea opaca* is very fine; *Todea pellucida* was growing in a well-drained pot in fibry peat, the pot in a pan of water, and the plant with a glass over it; and *Goniophlebium subauriculatum*, in a basket suspended from the roof, with fronds 10 feet long, nearly reaching to the floor.

We scarcely step outside and take a breath of fresh air before we pass into a vinery 57 feet long by 18 wide, which is divided into two compartments. The Vines are planted outside; but the border has been covered with glass to remedy the non-ripening of wood, which it has done effectually. What a nice place this covered border would make to winter bedding stuff! Prior to covering the border with glass the Vines did very indifferently, and Grapes coloured badly, but they now colour well. Under the Vines were several Ferns—as *Cibotium Scheidii*, 10 feet through; the beautiful *Adiantum chilense*, the Fingers-and-Tongue Fern, *Dictyoglossum criuium*; *Angiopteris evecta*, with fronds 9 feet long, and the plant 10 feet in diameter; *Polystichum triangulum*; *Asplenium polyodon*, and *A. pumilum*, with a host of other varieties. Besides Ferns, there were also *Selaginellas atro-viridis*, *erythropus*, *rubricaulis*, *Wallichii*, and *Lobbi*, all conspicuous for their Fern-like habits. In addition to these were a full collection of Lycopods, and amongst other things *Punica granatum* in fruit, and *Stenochlana scandens* in a pot looking for a wall. The back part of one division was covered with the Night-blooming Cereus, and a large collection of Cacti on a broad shelf at its feet. In a glass was *Vallisneria spiralis*, in which you watch the flow of the sap with the microscope; and *Caria vulgaris*, another microscopic object, both, of course, immersed in water. Stepping outside, a border filled with Stocks, Asters, &c., looked well.

The Rhododendron-house is the next we come to. It is

span-roofed, 100 feet long, 21 feet wide, 8 feet high at the sides, and 18 feet in the centre. It is heated by hot water, and kept at greenhouse temperature. It is ventilated at the top and sides. There is a shelf about 2 feet wide all round, on which plants in pots are grown; next to this is a wide path, and a bed in the centre in which *Rhododendrons* are planted, being chiefly Sikkim and Bhotan varieties, though some of the finer British hybrids are introduced. In the centre of the house a fountain is continually playing, and imparts a cool and refreshing character to this delightful promenade. Of *Rhododendrons* from Sikkim there were Aucklandi, argenteum, Dalhousiei, Edgeworthii, Falconeri, Hodgsoni, Thomsoni, Wightii, and Wallichii; and of Bhotan—Boothii, Hookeri, Kendrickii longifolium, Nuttallii, virgatum, album, Windsorii, leucanthum, &c., most of which have flowered, and are now studded with buds for another year.

In the same border were *Acacia affinis*, touching the glass; *Berberis nepalensis*, 10 feet high; *Lomaria ferruginea*, the same; and *Theophrasta imperialis* growing like a willow. In pots were *Acrophylum venosum*, 4 feet by 3; *Acacia lineata*, 5 feet by 4; *A. Drummondii*, 4 feet in diameter and feathered to the pot; *Ceratopetalum gummiferum*; *Philesia buxifolia*, good plants; and very many specimens of greenhouse plants representing almost every genus of hard-wooded plants from temperate climes. *Desfontainia spinosa* was in flower, the scarlet bloom contrasting well with the holly-like foliage. *Eugenia Ugni* does extremely well in this house, giving some fine peculiarly-flavoured fruit. A large *Camellia* (double white), literally bristles with flower-buds. Last winter it had more than eight hundred blooms expanded upon it at one time. It is about 12 feet in diameter and 10 high. But the greatest charm of the *Rhododendron*-house is the beautiful collection of British and exotic hardy-Ferns. They are placed on the north side of the house and so receive a certain amount of shade from the shrubs that are planted in the border. The collection is replete with every known distinct variety, and I would advise hardy-Fern-lovers to take the earliest opportunity of seeing this charming collection. Amongst them were *Blechnum L'Hermieri*, the best of the rosy-fronded species, and it, with *Lomaria Patersonii*, is first-rate for the dinner-table; *Adiantum pedatum*, a deciduous species, but now second to no Maiden-hair in cultivation, the plant was 3 feet through; *Blechnum spicant ramosum*, with the ends of the fronds crested; *B. spicant imbricatum*, having the appearance of a double-fronded variety; *Scelopendrium vulgare marginatum papillosum*, with pocketed pinna; and a legion of other multifid varieties of this beautiful genus; *Polystichum Crawfordii*; *P. aculeatum densum*, very fine; *P. angulare Footi* and *cristatum*, adjoining which is a mass of *P. lenchitis* from the Highlands. *Athyrium* multifid in all ways and fashions were here, some with beautiful plumes, others with tassels, of which *Frizelliae* and *Fieldii* (Ivery's), are fine; also, the rare *Woodsi* *ilvensis*, worse to get hold of than to grow; *Mohria millifolia*, very like a Yarrow; *M. thurifraga*, and the exceedingly handsome *Lastrea Filix-femina plumosum*; a mass of *Asplenium trichomanes incisum*; regular clumps of *A. Halleri* and *A. fontanum*; pots full of *Hymenophyllum unilaterale* and *H. tumbridgense*, both in sphagnum, bits of freestone, and fibry peat; the pots in a pan of water, and a bell-glass over the plants, which is taken off and wiped inside occasionally, but replaced immediately. *Trichomanes radicans* was growing luxuriantly in pieces of freestone, fibry peat, and a little of the infallible cocoa-nut stuff intermixed. The pot of this also stands in a pan of water with a bell-glass over it to secure a moist atmosphere. I cannot leave this beautiful collection without recommending everybody to go and see it. It alone will amply repay a visit, for the few I have named are but a speck in comparison to the whole.

Leaving the *Rhododendron*-house, our way is down a gentle declivity, with *Azaleas* and other shrubs to the right and left, and alpine or herbaceous plants in every nook, but presently we come to the long walk which is gay with annuals and very fine *Digitalises*; behind which, to the left, is a row of *Aracaria imbricata* and *Cedrus deodara* alternately. The trees were raised from seed about twenty-four years ago, and have now attained 12 feet in height. The other side of the walk is planted with *Rhododendrons*, *Azaleas*, and other flowering shrubs, the soil of the garden suiting *Rhododendrons*, and they sow themselves, and on many

plants the buds may be counted by the thousand. This walk, as may be imagined, is one blaze of bloom in early summer. No one would imagine that behind the *Araucarias* and *Cedars* is a plot of ground devoted to the growth of vegetables; but such is the case, and some very creditable work in that way is done. Still glass, the prevailing feature, again demands attention.

There is a Melon-pit 62 feet by 8, with a walk along the back, and a raised bed in front, on which fine-flavoured and large Melons are grown. There are hot-water pipes for top and bottom heat. The surface of the bed is about 1 foot from the glass; consequently the vines or shoots run on the surface, thereby saving a trellis and much trouble in tying. Although the majority of the fruit had been cut, there were some remaining, convincing me that hot water is a first-rate system of growing Melons. The sorts most in repute here are Golden Perfection, Emperor of China, Orion, and Excelsior.—G. A.

(To be continued.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

As young weeds will now begin to appear thick and fast, the hoe should be kept actively employed on all favourable occasions to cut them down. Also hand-weed the seed-beds; for if neglected for a week or two the weeds will overrun and seriously damage them, and then increase the labour of removal tenfold. *Cabbage*, plant the principal crop of spring Cabbage on ground well manured, as previously directed. The East Ham is a good variety for standing over the winter, it is not so apt to run in spring as other sorts. Prick-out into beds, a few inches apart, a large quantity of Cabbage plants which have just expanded their first two rough leaves, they will be required in spring. *Cauliflowers*, prick-out the young plants as soon as they are sufficiently large to fix properly in the soil. Some may be pricked into a sheltered border, and some into frames. *Lettuce*, make the last sowing for the season of Brown Cos and Hardy Green on raised beds of light soil where they may remain till spring, and be planted-out to succeed these that are transplanted this autumn under walls, &c. *Mushrooms*, the time has now arrived when they may be grown with the greatest probability of success. Although to some it may appear an easy task to produce them at all seasons, nevertheless for the great majority of growers a limited supply will be sufficient, when advantage can be taken of the natural warmth of the season to grow them with the least expense of labour and of time. The bed to be made of fresh warm stable-dung that has been prepared for a fortnight or three weeks by forking it up into a heap, removing all the long straw and litter, and turning it over every two or three days until the rank steam has passed away, and the whole is in a mellow condition and of equal consistence throughout the heap. If during this time it has been kept dry, it will now be fit to be made into a bed 4 feet wide by 3 or 4 high and any length that may be required, about the same shape as a Potato-pit or the ridge of a house. A great portion of the success will depend upon the firm manner in which the bed is built; this is generally done by beating with a three or four-pronged fork as solid as possible, the top when it is reached to be about 6 inches wide. Watch-sticks to be put in the bed and allowed to remain until the heat, which is known by the feel of the watch-sticks, has declined to a milk-warm state, when the bed will be fit for spawning. The bricks of spawn to be broken into moderately-sized pieces, inserted about 2 inches within the surface and about 5 or 6 inches apart all over the sides and ends of the bed, to be well beaten in with the hand. In a week or ten days the bed will be fit to be covered all over, 3 inches deep, with good sandy loam; or, if no better can be had, any good garden soil to be put on with the hand, well pressed and occasionally knocked-in a little with the back of a spade, to be covered about 6 inches thick with dry hay or straw. The bed should be made in a dry sheltered situation, on level ground. In some low situations it is advisable to lay some brushwood at the bottom, and cover with a little long litter on which to build the bed. The watch-sticks, when they feel nice and warm, will give the best clue to the proper time for spawning

and for covering over the bed, and also when to supply or withhold the external covering of hay or straw. Let it be watered occasionally when the surface becomes dry, and in cold weather with tepid water. *Onions*, pull up those that have done growing, and heuse them in a dry state. They should be sorted before being laid away in the root-cellar, and thick-necked ones used first. Embrace the opportunity of a wet day to string the *Onions*, to tie-up and arrange herbs, and to beat out and clean the seeds of any favourite vegetable that may have been saved.

FLOWER GARDEN.

Continue to plant-out *Pinks*, *Clove Carnations*, &c. See that the plants already established in beds are kept in a state of health and vigour by stirring the surface of the soil. Look now and then at the late-budded *Roses*, and loosen the ligatures when necessary. Borders deficient of *Snowdrops*, *Crocus*, *Narcissi*, and other such early spring-flowering bulbs should have some introduced.

FRUIT GARDEN.

Fruit, as the *Apple* and *Pear*, will now be ready to gather in rapid succession, having come to maturity earlier this season than usual. Great care should be taken with them to prevent their being bruised. The best and most handsome fruit only should be stowed away, the rest will do for present use. When gathering, take care not to break off the fruit-spurs. Give *Grapes* on *Vines* against walls the full benefit of the sun by taking away a few of the leaves which shade them.

GREENHOUSE AND CONSERVATORY.

The weather has assumed a more favourable aspect, and many may hesitate in the work of introducing the house plants while the promise of a late summer is before them. It is dangerous, however, to trust anything to the weather at this period of the year. Cloudless days are very delightful, and thrice welcome just now; but it sometimes happens that they are succeeded by clear nights, when nipping frosts occur: therefore the kindly work should proceed uninterruptedly. Let a scrupulous examination be made of the condition of each plant, and defects in the soil or drainage of the pots at once remedied. Clear off moss, remove insects, and replace stakes. The ordinary precautions for obtaining a supply of common flowering plants throughout the winter months should be commenced and progressively continued. *Violets* to be potted or planted in a frame; *Mignonette* thinned and sown; *Hyacinths*, *Tulips*, and other bulbs potted and plunged; *Pinks* for forcing encouraged; and *Cinerarias* duly attended to. *Roses* in pots should occupy a fair share of attention. The *Chrysanthemums* to be taken up from the open ground, to be potted in any good soil, watered, and shaded for a few days. The system of growing them in the open ground saves immense labour in watering, and, after all, it is rare to see them in pots well feathered with foliage to the bottom; but by the open-ground system they require but the small attention of stopping occasionally; and when they are potted, even if left in the open ground until the flowers are expanding, they will not lose a leaf.

PITS AND FRAMES.

Some cold frames should now be put in readiness for the reception of alpine plants in pots, especially the more delicate species, to remain for the winter, or it is the destruction of this humble but interesting class of plants. Bear in mind they must not be covered with the lights during fine weather, but only in times of rain. Continue to get those structures which may have been used for horticultural purposes during the summer months in readiness for winter stock, by white-washing the walls, cleaning the flues, &c. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

GENERAL routine much the same as last week. Planted out all spare ground with *Broccoli*, *Scotch Kale*, *Brussels Sprouts*, *Savoy*, and *Cauliflower* to get a little protection. Took means for protecting on an emergency a nice bed of *Dwarf Kidney Beans* now coming into bloom. Sowed some in pots out of doors, to be moved under glass as the weather gets too cold for them. Pulled up the late *Onions*, and put them under cover to

dry, and the stringing of them will be a job for a wet day. Scattered lime, and wood ashes, and soot over late sowings of *Lettuces*, *Cauliflower*, &c. Pricked out *Cabbages* for the earliest spring crops. Sowed a small pinch to stand the winter. Earthed-up *Celery* fully in a dry day, having three-parts done it a fortnight ago: this will be our second lot. Reasons were lately given why the bit-by-bit earthing should not be proceeded with. No ground better for the main *Cabbage* crop than where *Onions* have been grown. The ground, however, to be well stirred; and if fresh manure is given, that to be placed in the bottom of the trench, and some of the surface rich soil left again for the young *Cabbages* to root in. Though *Cabbages* thus succeed, *Onions* well, the opposite rule will not hold, for *Onions* are almost sure to fail if they succeed *Cabbages* that have stood long on the ground. Pulled *Cucumbers* out of large pots that were doing little good, though the reason why is a mystery. Younger ones in a bed are bearing beautifully. As stated the other week, this at present is our main sheet-anchor against disease and failure. Every pot was filled with a different soil or combination of soils, and there was not a pin to choose between them. Those planted out in the pit are in rich soil, and as beautiful as can be, and bearing fine fruit; but so did all our *Cucumbers* until about the end of June, and since then hitherto in succession they have been less or more affected. Spawned and earthed-up the first bed of *Mushrooms* in the *Mushroom-house*. Have seen some handsome *Mushroom-houses* of iron and slate of late; but after all, from what comes before us in the way of complaint, we come to the conclusion that the want of success is chiefly to be traced to three things—bad spawn, overheating, and overworking or overdrying of the dung. Too much wetness is also to be avoided; but when the matter was so wet that moisture could almost be squeezed out of it, we have had fine *Mushrooms* from wrapping each piece of spawn in a good handful of short dry litter before inserting it in the bed. We like to see good structures for all work; and gentlemen should show the example of having nice, solid, and lasting buildings for all that is needed about their establishments; but at the same time more humble people may do much with more humble means. We know a farmer who supplied his friends and himself liberally with *Mushrooms* from Christmas right on to June at any rate from a bed in a stable, and a doctor has just been a little less successful from a bed in a disused stall of his stable; and, as stated the other week, *Mushrooms* may be had under the most simple arrangements, though the greater the means the less excuse for failure when it comes. Cut off the larger leaves from *Tomatoes*, that the sun might have more power to ripen the fruit; and placed the pots of *Capsicums* and *Chilies* more in the sun, that the fruit might be well hardened for grinding for *Chili pepper*, as it is said that a good portion of what is sold is made up of red lead; but perhaps it is all a story.

FRUIT GARDEN.

Gathered fruit as it ripened. It is better to get *Peaches*, *Nectarines*, the finer *Plums*, and even *Apples* before they are so ripe as to drop. A *Peach* gathered a few days before dead ripe and kept in a dry place, not too cold, will, when used, be in a finer state, as to flavour and softness throughout, than when allowed to hang on the tree with one side rather ripe and the other side rather under-ripe. We have seen *Peaches* placed in a cool place to keep them, but it always injured the flavour. Nipped shoots of fruit trees as needed, to swell the buds near home. Gathered some good *Figs* out of doors, never did this so early before; the house still giving a few each day. Those who grow *Pines* must be careful not to check them now in their growth. Those showing and in bloom should have more heat and air to cause them to come strong and robust. Gave more firing to vineries to keep the growth in a healthy state, and more air to prevent damping in these dull days and wet weather. The borders outside being rather dry, have allowed the rains free access. If it had not been so would have protected the earliest house from heavy rains. Syringed all the *Peach* trees on trellis or in pots done fruiting, with sulphur water to clear away any vestige of red spider. Went over *Strawberry* plants in pots, taking out every weed and cutting off all incipient runners, and placing the pots a little further apart, so as to give them more room for the autumn sun to rest upon them.

ORNAMENTAL DEPARTMENT.

Fresh dressed conservatory. Mowed and rolled lawn and walks. When very wet scarcely any walk is so hard but it will leave traces of feet behind. Some folk seem to feel a pride in thus spoiling a beautiful surfaced walk. In a fine day you will never see them put a foot on it; but only let us have a few wet

days, and every fair moment out they will come and perambulate backwards and forwards as if a task were assigned to them to make as many marks as they could with hob-nailed shooting-boots. Perhaps it gives them a pleasure to notice the trouble there is in taking out all such marks before the walk can be at all presentable. It matters not that there are stone walks and walks with rougher surfaces; they must choose the smooth walk, just because there they can leave their marks behind them. Just on this account alone we would almost as soon see a drove of pigs in a pleasure ground as some good people in a wet rainy day. If there is a smooth soft place in the walks be sure they will find it out, and leave as many marks as if they had been dancing a hornpipe on it. Went on as fast as we could with propagating Geraniums, and with picking and freshening the beds; and as in the ribbon-borders the fine double Grandiflora Feverfew was much injured by the dry weather, have cut the most of it out, and drawn the Perillas and the Trentham Rose closer together; and as they are both strong the loss of the Feverfew is not noticed, farther than the white told well between the rose and the purple.—R. F.

COVENT GARDEN MARKET.—SEPT. 5.

All kinds of fruit and vegetables continue very abundant, and well-fruited is especially so. Grapes and Pine Apples are sufficient for the demand; of the former the prices for some of inferior quality rule rather lower than last week; but the best qualities fully maintain their prices. Of Melons there is a good stock, both of British and foreign. Pears consist chiefly of Williams' Bon Chrétien, and Beurré d'Amanlis; of the former there is a large supply. Filberts are still rather short, and prices are rising. Some good Cobs have made their appearance at from 45s. to 50s. per 100 lbs. The Potato market is still heavy. Flowers consist of Orchids, Pelargoniums, Verbenas, Dahlias, Asters in abundance, Stocks, Fuchsias, Calceolarias, Mignonettes, and Roses.

TRADE CATALOGUE RECEIVED.

J. C. Padman, Providence Nurseries, Boston Spa, Tadcaster.—*Select List of Bulbs, Hardy Ferns, and Roses.* 1863.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SEEDLING POTATO (W. J. Epps).—Your seedling Potato boils to a perfect ball of flour, and is of excellent flavour.

VINE LEAVES BLOTCHED (S. G.).—Your Vine-leaf appears to us to have been blotched through allowing water to stand on the leaves when the sun was shining powerfully upon them. We rather suppose that your border is a very rich one, and that growth is consequently induced at a time when the wood should be ripening. Keep the atmosphere drier by giving abundance of air; and if any syringing be done, do it early in the afternoon, leaving a little air on all night, which will aid in keeping the atmosphere of the house pure, and in preventing water lodging on the tips of the leaves. If the sun strikes any leaf on which water has stood some time it cannot do otherwise than discolour it by carrying off its juices as well as the water on the leaf; and with the loss of the juices the leaves contract or curl in proportion to the quantity lost.

KEEPING GRAPE (West House).—If you do not care about wintering any plants in the house Grapes keep longer without shrivelling on the Vine than when cut; but in houses where plants are wintered it is better to cut them off with a few inches of wood attached about the time the leaves fall off, searing the end with a red hot iron, and then sealing it up with sealing-wax. Hang in a dry room, and cut out all decayed berries, examining frequently for that purpose. If you prefer keeping the Grapes on the Vine, not even a plant requiring water should remain in the house; but by admitting air and using firing in the daytime keep the atmosphere pure and dry. When pruning time arrives prune those branches on which the fruit is hanging by taking out all the eyes except those which should be left for growth in the following season if the Vines were pruned in the ordinary way; then leave the branches alone until the eyes have fairly broken, when they may be removed, as there is then no danger of bleeding. They are sure to bleed if cut off at the time the Grapes are cut, if these be allowed to hang much after the turn of the days.

STOVE CLIMBER (A Subscriber in the North).—Instead of one there are half a dozen to choose from. *Thunbergia Harrisii*, purple; and *T. laurifolia*, of the same colour; *Schubertia graveolens*, pink bluish, and sweet-scented; *Allamanda violacea*, violet; *Henfreyia scandens*, cream and spotted; and *Mandevilla suaveolens*, white, very fragrant.

KIRTLAND'S BEURRÉ PEAR.—PRO-PAGATING CENTAUREA ARGENTEA (J. F.).—This is an American Pear raised by Dr. Kirtland, of Ohio. You will not find it first-rate in this country. It ripens in September. *Centauria argentea* may be propagated at this season by small side shoots slipped off when about 3 inches long, and inserted round the sides of a small pot, and all the leaves removed except two or three of the smallest at the point. If the plants are in pots it will be best to keep them as they are till the end of February. Then place them in a heat of 60°, and strike the young shoots when 2 or 3 inches long in a mild bottom heat.

GUANO WATER (A Subscriber).—Half an ounce to a gallon of water is strong enough for potted plants, and 1 oz. to the gallon for plants in beds.

EUCHARIS AMAZONICA (Notice).—The treatment is more simple than that of a Hyacinth or Tulip, and it is very difficult to prevent its blooming. It is a stove bulb with very thick leaves; and all stove bulbs with stout, fleshy leaves like a start for the yearly growth in moist bottom heat from six weeks to two months, and the bottom heat to be just 10° hotter than the heat of the air for the leaves. From 70° to 75° is the right bottom heat for this charming plant, and for ninety-nine out of every hundred of such stove bulbs, and, of course, 10° lower for the air of the pit or hotbed after the middle of March. Between January and March, if any such bulbs are put to forcing, the top heat must be 15° lower than the bottom heat; but *Eucharis* will do and bloom without this start. The grand secret with all of this kind of stove bulbs is to have them cooler in the winter and in the height of summer than common stove plants. Fifty-five is the very highest degree any one of them should ever get from October to March; from March to June, bottom and top heat as above; and from June to the end of August, a well-aired greenhouse is the right place for them, and all the evergreen ones, like this *Eucharis*, to be in the stove, with abundance of air, and not much moisture, in September.

POKE (B. A. S.).—It is the Virginian Poke, *Phytolacca decandra*, of which, in North America and the West India, the young shoots are cooked and eaten as Asparagus and the young leaves as Spinach. When the plant becomes matured it is purgative and emetic, two spoonfuls of the juice purging actively. The berries stain an intense purple colour, and are used in colouring wine. They are said to be narcotic; the root is also so, and powerfully emetic. We would not recommend you to use it as Spinach.

SEEDLING HOLLYHOCKS (E. Miles).—Your young plants pricked out 4 inches apart in a bed are sure to flower well next year. They will be strong bushy plants by March, when they may be removed to their final position. If the winter be unusually severe, a little Pea-haulm or something of that kind might be thrown over them at the time, but it is not likely that they will require it. The only danger is when they are in a fast-growing condition at the time severe frosts set in. If growing in an exposed place this is not likely to be the case.

WINTERING SEEDLING PELARGONIUMS AND CARNATIONS IN A COLD FRAME (E. Miles).—We fear the damp will be fatal to your Pelargoniums; but if you could contrive to keep them in some airy room, even if not very light, for a few weeks in the duller part of the winter—say from the middle of December to the end of January—they would do afterwards in the cold frame, if protected at night as you mention. The Carnations will take no harm; but you must gradually harden them off so as to plant them out in March, otherwise they will become drawn.

PLANTS BY POST (North Britainer).—No authority is needed. We have sent small plants and cuttings by parcel post. Of course you would not send balls of earth, much less flower-pots, for you pay according to weight.

COLOURED PLATES OF FLOWERS (N).—We do not know any but those in Mrs. Loudon's quarto volumes. As you object to periodicals it is needless for us to name any.

MILDEW ON ROSES (A. S. A.).—Mildew on Roses may be prevented by syringing them with a decoction of laurel or elder leaves, and it may be removed by dusting the infested parts with flowers of sulphur. Mildew is caused by a peculiarly diseased state of the plant infested, but what that peculiarity is remains an unsolved problem. See to the roots of your Roses, and ascertain if there be no stagnant water near them. Perhaps they are deep in the soil and produce long gross growths; if so, lift them in the beginning of November, and if the ground is wet drain at once. Manure them if weak, pruning more closely than when vigorous. Mildew on Vegetable Marrows is successfully removed by dusting the leaves and stems with sulphur.

LONG HEATHER FOR THATCHING (*C. Ellis*).—About Bagshot and Woking we think you might obtain some; and if we required any in that neighbourhood, we should write to some of the nurserymen there and ask them to tell us how best to obtain the Heather.

BOOK ON MUSHROOM-CULTURE (*W. R. J.*).—We know of no good separate work on Mushroom-culture since Abercrombie's, "The Garden Mushroom," published sixty years since. It is only met with at second-hand book-shops.

WEEDS ON LAWN (*T. W. C.*).—The way to have a clean lawn is to root up all weeds as fast as they appear. Root up Daisies, Plantain, Dandelion, with the weed enclosed, at once. Never heed what people tell you about their appearing in greater force. It is new to hear of Plantains growing again when once removed, or Daisies either. It is tap or fleshy-rooted plants that have the power of forming eyes on the root after the top is removed, as Dock, Dandelion, and Thistles; but even these soon perish if the top be removed immediately after its re-appearance. Cut up the Dandelions with a long-bladed knife as much below the surface as possible, removing Plantains, Daisies, &c., with a common grubber, and serving Ranunculus repens the same; but the weed enclosed must be pulled up with the hand. Persist in this—digging up Dandelions with the knife, grubbing up Plantains, and pulling up the weed and grubbing up the roots, and you will find patience and perseverance will be well rewarded; but you must not let them get ahead or the weeds will become re-established. There is no plant that can exist without an annual production of leaves; and if you keep the weeds on your lawn grubbed up as fast as they appear you will find they must perish as they do elsewhere. Manure by all means between now and next March, and in May sow Clover (*Trifolium filiforme*), adding a few pounds of *Festuca ovina*, *F. tenuifolia*, *Bucetum pratense*, and *Anthoxanthum odoratum*; or obtain a few bushels of lawn mixture, to be had of any nurseryman, and sow it early in April, rolling the lawn immediately after. As you object to manuring the lawn, mix a ton of lime with four of rich soil, and apply this half an inch thick during dry weather in March, which is a ready way of killing moss, besides forming a capital medium for the grass seed to vegetate in. Harrowing is not necessary, a good rolling being sufficient to fix the seed of grasses.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*Eaton Cliff*).—The white flower with Fern-like leaves is the *Spiraea filipendula*, commonly called Dropwort. This plant and its varieties are ornamental border flowers, particularly the double-flowered kinds. It is very frequently found growing wild in woods, thickets, and upon chalky downs. The Fern is *Asplenium adnigrum*, a very pretty dwarf-growing hardy kind. It delights in loam and peaty soil when planted in a shaded situation. The leaf is from the *Dielytra spectabilis*. The reason you could not find the name under which you had it in any book on plants is that the name was wrongly spelt. You will find the name of this beautiful plant in the "Cottage Gardener's Dictionary," with an excellent account of it too. Although we have it so very fine in the open border rising some 2 to 3 feet in height and as much across, very heavy rains and high winds disfigure its young stems, leaves, and beautiful blossoms very much at times; but well-grown plants with plenty of pot-room form very beautiful specimens for the conservatory or greenhouse, both for early and late spring months. (*John Gray*).—We only undertake to name four or five specimens at a time. 3, *Cassebeera hastata*; 4, *Alseous crispus*; 5, *Davallia novæ-zelandiæ* (?); 6, *Adiantum assimile*; 7, *Asplenium fontanum*; 8, *Pteris chinensis*; 9, *Osunda regalis*. (*C. M. M.*).—*Onoclea sensibilis*. Babington says it is naturalised in one spot near Warrington. (*H. T.*).—1, *Tormentilla officinalis*, the common Tormentil; 2, *Cerastium vulgatum*, the common Monsear Chickweed; 3, *Cardamine hirsuta*, the Hairy Bittercress.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RELATIVE ENTRIES OF VARIOUS BREEDS AT POULTRY SHOWS.

IN reading the report of the late chicken Show at the Agricultural Hall at Islington, as given by a daily paper, I was struck by the remark that Dorkings were at the head, and that entries were far more numerous than that of any other class!

Taking, then, the catalogue of this Show as my text, I have made a few calculations which I have tabulated as follows:—

Breed.	Number of Exhibitors.	Number of Entries.	Amount offered in Prizes. £ s. d.	Amount obtained by Entries. £ s. d.
Spanish.....	17	...	30	13 0 0
Dorking.....	27	...	69	23 10 0
Cochin.....	25	...	42	21 0 0
Brahmas.....	11	...	25	10 0 0
Game.....	25	...	53	32 10 0
Hamburghs.....	28	...	35	30 0 0
Polish.....	7	...	13	15 0 0
Malay.....	2	...	3	4 0 0
Other Breed.....	9	...	12	5 0 0
Bantams.....	30	...	54	21 0 0

Taking these figures we may notice that, albeit the Dorking may be the popular fowl, yet in number of exhibitors that breed is exceeded by Bantams and Hamburghs. Cochins and Game treading very closely on their heels, if, in speaking of poultry, it is allowed that they have any. Bantams,

it must be remembered, paid only 3s. entry; why, it is difficult to understand. This may not, perhaps, have influenced the entries very much, but I apprehend it does more than framers of regulations imagine.

In number of entries the Dorking is at the head very decidedly, giving by entry to the coffers of the Company £17 5s. out of the £23 10s. offered in prizes—about three-fourths in fact. But, what have we No. 2 as, in fact, the second best payer in proportion to prizes offered?—Listen ye compilers of the Bath and West of England schedules, and ye men of Worcester and the Eastern Counties—Why, Brahmas! True, they were never before so liberally invited; but, equally true, they responded liberally to the invitation, bringing back as their quota very nearly two-thirds of the prize money.

Some one says they were unusually numerous. I reply they were unusually treated; but it also remarks that they were unusually good. This, a glance at the prize list would not induce a non-visitor to believe. In the list of prizes and commendations there is only one new name to me, whilst there are many good names unnoticed. Possibly, it may be said of the classes generally, that the Judges were not lavish of commending—all the more honour where obtained. Cochins return exactly one-half, and Spanish somewhat over the half. Then the "abortions," with an attached adjective of the daily paper. The little Bantams came next. I could not but fancy the reporter considered they ought to be as large as the other breeds when he styled them as above. Then comes a terrible falling-off: Game did not bring back nearly half, and Hamburghs, Polands, and Malays bring the amount lower and lower. Still the former are invariably offered handsome prizes.

I have not noticed the Ducks. It strikes me that here the very liberal prize list of the Islington Show falls off. The prizes are very poor comparatively, and I think the Company would be the richer if they increased them, perhaps at the expense of some of the other breeds which do not muster as they ought. I say this although it affects breeds to which I am partial. This, however, appears plainly from the Islington Show, that the much-disputed breed, the Brahma, does not deserve in any Show professing to be good the "Any other variety" as its destination. They have fought their way up steadily but surely, and are daily better appreciated, and in many situations for general purposes are the most valuable fowl.—Y. B. A. Z.

SPARKENHOE FARMERS' CLUB POULTRY SHOW.

THIS popular Society has for many years past been gradually increasing in public favour, until at length there are very few local meetings that draw together so good an exhibition of poultry as this does: consequently the competition that invariably ensues always brings as goodly a muster of poultry amateurs as can be found even at shows of much higher pretensions. It is worthy of consideration that the really useful table poultry, of whatever description, have always been a great feature of the Sparkenhoe Meetings, and this year the same remark is equally deserved. To such a meeting, and with so liberal a prize list, of course to win at Sparkenhoe is invariably considered one of a poultry-breeder's most anxious desiderata.

We believe this is the only Society in the kingdom that offers the following premium—viz., for the best three pens of any variety or breed the property of one person, and to be entered solely and specially for this competition, one single restriction being that each pen is to contain a male and two females. This is the point beyond all others that elicits public attention—so much so, that the competition annually becomes stronger in this class, and the anxiety to know who may win the silver cup never flags. It is admittedly a matter of considerable difficulty to get three first-rate pens from any single yard; still, this year not less than eleven competitors entered for this premium.

The triumph was with the yard of Viscountess Holmesdale, and it was to such fowls an easy triumph. The Dorkings shown by this lady have thus been instrumental in securing a second silver cup in less than a fortnight for their fair owner, for at the London Islington Show last week they

took the cup for the best pen of fowls in that Show. At Sparkenhoe they again were successful. In the present instance they were shown with a really first-class pen of Black Spanish, and a remarkably good and well-exhibited pen of white Cochins of this present year. The winners of the second prize in this class are also well worthy of mention. The Black Game pen was especially good, and the Partridge-coloured Cochins were also first-rate; but the Spanish were far, very far, behind Lady Holmesdale's. Captain Buckley sent two capital hens, one of Grey, the other of White Dorking; but the Silver-pencilled Hamburg pen threw them out altogether. Mr. Everard, of Bardon Hill House, Leicester, showed two splendid lots, and both were highly commended. Mr. Warner's single entry was well entitled to the same position. Two really good pens and one faulty one pretty closely describe the particular entries of the remaining competitors.

In the general *Spanish* class were some good birds, and doubtless the prize chickens with care will greatly improve. Three hens were shown together in one pen, and, of course, were at once disqualified.

In the Grey Dorkings, Viscountess Holmesdale quite out-distanced all rivals. They were a grand pen, and one of the best pens shown this season. Mr. Everard's second-prize pen was also very good. There was scarcely any pen of White Dorkings so good as those that have been met with at previous meetings of this Society.

In Cochins (all colours competing), the entry was an indifferent one; in fact, the class as a whole was one of the most irregular in combs, &c., we have seen for some time past.

The Game class, White or Piles, except the winning pens, was a weak one; but the one for either Black Red or Brown Red Game fowls made ample amends. We regretted to see the Brown Red cockerel (second prize) so badly "dubbed," for in the hands of an expert cocker much more might be made of him.

The Golden-spangled Hamburgs were good, and a pen of Red Caps were shown among them. All the other varieties of Hamburgs were also superior, but the Silver-pencilled first-prize was one of the gems of the whole Show.

The Andalusians and the Silkies were capital in the Variety class.

A pen of Malays that were here badly exhibited would be hard to beat anywhere, if well shown.

The Chinese Golden and Silver Pheasant classes brought but two entries, one of either breed. They were, however, quite a credit to Mr. Lennard, who exhibited them.

In Aylesbury Ducks yellow bills were no unfrequent drawback. It is always a fatal objection. The Rouen Ducks and the Buenos Ayrean were, however, better than we usually find them.

Of the whole classes both of *Geese* and *Turkeys* we cannot possibly speak too highly. The "poultis" were by far the best we have seen this year, and some of the goslings were not less praiseworthy; but we must direct the attention of exhibitors that only one gander is admissible in each pen.

In *Guinea Fowls* a second prize was withheld; the rule being for pairs of birds in this class, not three; disqualification was inevitable. The *Bantams* were not of high character.

The show of *Pigeons* and *Rabbits* was excellent and caused great attraction. Although the weather throughout the whole night previous to the public admission was fearfully wet, about 8 o'clock A.M. the sun broke brightly, a fine day ensued, and the company was a large one, the whole Show going off right merrily.

Silver Cup, Viscountess Holmesdale, Linton Park, Staplehurst, Kent (Grey Dorkings, White Cochins, Black Spanish). Second, H. Yardley, Market Hall, Birmingham (Black Spanish, Partridge, Cochins-China, Black Game). Highly Commended, W. T. Everard, Bardon Hill House, Leicester (Duckwing Game, White Dorkings, Brown Red Game, Grey Dorkings, Aylesbury Ducks, Black-breasted Red Game); H. Warner, The Elms, Loughborough (Black-breasted Red Game, Grey Dorkings). Commended, G. Bott, Sheepy, Atherstone (All three pens Brown Red Game).

SPANISH.—First, E. Morley, Sapcote, Hinckley. Second, W. T. Everard, Bardon Hill House, Leicester. Highly Commended, H. Yardley, Market Hall, Birmingham.

DORKING (Coloured).—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, W. T. Everard, Bardon Hill House, Leicester. Highly Commended, A. Guy, Eaton, Grantham; H. Warner, The Elms, Loughborough. Commended, W. Trussell, Moira, Ashby-de-la-Zouch; Mrs. P. Wolferstan, Statfold Hall, Tamworth; W. T. Everard.

DORKING (White).—First, Mrs. Wolferstan, Statfold Hall, Tamworth. Second, W. T. Everard, Bardon Hill House, Leicester.

COCHIN-CHINA.—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second H. E. Emberlin, Humberstone, Leicester.

GAME (White, Piles, and light colours).—First, C. B. Lowe. Second, W. T. Everard, Bardon Hill House, Leicester.

GAME (Red, and other dark colours).—First, G. Bott, Sheepy, Atherstone. Second, C. Lea, Rowden, Hinckley. Highly Commended, J. M. Baker, Hall End, Tamworth; Mrs. Milhouse; T. Horley, Jun., The Fosse, Leamington; C. E. Lowe, Sheepy Hall, Atherstone; H. Warner, The Elms, Loughborough; Dr. Hitchman, Mickleover, Derby. Commended, W. Baneroff, Clifton; G. Bott.

HAMBURGS (Gold-spangled).—First and Second, H. E. Emberlin, Humberstone, Leicester. Highly Commended, Captain Buckley, Desford.

HAMBURG (Gold-pencilled).—First, Captain Buckley, Desford. Second, J. Holt, Nuneaton. Highly Commended, G. Jones, Earningham. Commended, J. Choyce, Harris Bridge, Atherstone.

HAMBURG (Silver-spangled).—First and Second, J. Holt, Nuneaton. Highly Commended, Mrs. Wolferstan, Statfold Hall, Tamworth; Captain Buckley, Desford.

HAMBURG (Silver-pencilled).—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, J. Holt, Nuneaton. Commended, T. Charlesworth, Leicester.

ANY OTHER DISTINCT BREED.—First, C. B. Lowe, Sheepy Hall. Second, J. Meredith, Merevale, Atherstone. Highly Commended, J. Meredith; J. Choyce, Harris Bridge, Atherstone.

PHASANTS (Golden).—Prize, S. Lennard, Leicester.

PHASANTS (Silver).—Prize, S. Lennard, Leicester.

DUCKS (White Aylesbury).—First and Second, H. E. Emberlin, Humberstone, Leicester.

DUCKS (Any other variety).—First, C. E. Lowe, Sheepy Hall, Atherstone. Second, J. Choyce, Harris Bridge, Atherstone. Highly Commended, A. Smith, Baxley Hall, Atherstone; J. Choyce. Commended, W. Trussell, Moira, Ashby-de-la-Zouch; Captain Buckley, Desford; J. Choyce.

GESE.—First, G. Cowper, Seagrave, Loughborough. Second, Baroness de Clifford, Kirby Mallory, Hinckley. Highly Commended, S. H. True-love, Hoppesford, Coventry; Baroness de Clifford. Commended, J. M. Gandy, Drayton, Nuneaton.

TURKEYS.—First, J. Coxon, Freeford, Lichfield. Second, S. H. True-love, Hoppesford, Coventry. Highly Commended, W. Winterton, Hinckley; Mrs. A. Guy, Eaton, Grantham; J. Taylor, Weddington, Nuneaton.

GUINEA FOWLS.—Prize, J. Johnson, Braunstone, Leicester.

BANTAMS.—First, W. T. Everard, Bardon Hill House, Leicester. Second, H. Warner, The Elms, Loughborough.

POSSONS.—*Parrots or Croppers*.—First, Rev. R. W. Fisher, Alton, Cheddale. Second, J. Langham, Belgrave, Leicester. Highly Commended, H. E. Emberlin, Humberstone, Leicester; Rev. R. W. Fisher. Commended, J. Langham.

Carriers.—First, Rev. R. W. Fisher. Second, H. Yardley, Market Hall, Birmingham. Highly Commended, H. E. Emberlin.

Tamblers.—First, W. Choyce, Sison, Atherstone. Second, H. Yardley. Commended, J. Langham.

Fantails.—First, W. Choyce. Second, H. E. Emberlin. Highly Commended, W. Choyce; H. Yardley. Commended, H. Yardley; J. Langham; E. Nason.

Any other distinct variety.—First, W. Choyce. Second, H. Yardley. Highly Commended, J. Smith (Jacobins). Commended, W. Choyce (Nuns); J. Smith, Walsall (Arch-angels); H. Yardley.

RABBITS.—*For Weight*.—Prize, G. Jones, Birmingham.

For Length of Ear.—First, G. Jones. Second, W. Chamberlain, Desford, Leicester. *Any other kind*.—First, W. Chamberlain. Second, Master J. A. Geary, Daddington. Highly Commended, G. Jones. Commended, W. Choyce.

Mr. Edward Hewitt, of Sparkbrook, near Birmingham, officiated as the arbitrator of the poultry, Pigeon, and Rabbit department.

DEWSBURY POULTRY SHOW.

THE field in which the annual Show was held on Wednesday, August 26th, is situated in Savill Town, in Thornhill, and about 250 yards as the crow flies from Savill Bridge. It was admirably suited for the purpose for which it was used, and being well drained the herbage was quite dry, despite the rain of the day before.

In Cochins some fine birds were shown, the first prize in the adult class and both the chicken prizes being won by white birds. In Spanish there was close competition. The chicken prizes were easily won by local exhibitors, and we think these would be more successful in the adult class were they not so easily tempted to part with their best birds to other exhibitors. The Hamburgs as usual were good, as were the *Polands*, the prizes with few exceptions going to Miss Beldon and Mr. Dixon. In Game fowls there were good birds shown; the prize birds with few exceptions would have been successful at the principal shows. *Bantams* were not so numerous as formerly. We missed some of our old exhibitors in these classes.

In the classes for Ducks there was but one pen of Aylesbury. The Rouen were first-rate. There were about sixty pens of Pigeons, most of which were good birds and formed a very attractive feature of the Show. At one time it was next to impossible to obtain even a cursory view of some of the pens. The Rabbits were good and much admired.

COCHIN-CHINA.—First, W. Dawson, Hopton, Mirfield. Second, J. Dixon, Bradford. *Chickens*.—First and Second, W. Dawson.

SPANISH.—First, Miss E. Beldon, Gilstead, Bingley. Second, J. Dixon. *Chickens*.—First, T. Greenwood, Eastfield House. Second, J. S. Senior, Batley Carr.

DOAKING.—First, Miss E. Beldon. Second, J. Dixon. *Chickens.*—Prize, E. Leech, Greave House, Rochdale.
HAMBURG (Golden-spangled).—First, J. Dixon. Second, Miss E. Beldon. *Chickens.*—First, J. Dixon. Second, H. Himsforth, Lupton.
HAMBURG (Silver-spangled).—First, J. Dixon. Second, Miss E. Beldon. *Chickens.*—First, Miss E. Beldon. Second, J. Dixon.
HAMBURG (Golden-perilled).—First, J. Dixon. Second, Miss E. Beldon. *Chickens.*—Prize, J. Dixon.
HAMBURG (Silver-pendilled).—First, J. Dixon. Second, Miss E. Beldon. *Chickens.*—First, Miss E. Beldon. Second, J. Dixon.
POLANDS (Golden or Silver-spangled).—First, Miss E. Beldon (Silver). Second, J. Dixon (Golden). *Chickens.*—First, J. Dixon (Golden). Second, W. Newsome, Bingley (Silver).
POLANDS (Any other variety).—First, Miss E. Beldon. Second, J. Dixon. *Chickens.*—First, J. Dixon. Second, W. Newsome.
GAME (Black-breasted and other Reds).—First, H. & C. Mason, Drighlington. Second, Miss E. Beldon. *Chickens.*—First, H. & C. Mason, Second, E. Naylor, Heckmondwike. Highly Commended, J. Brook, Gomersal.
GAME (Duckwings).—First, J. Riley, Chickenley. Second, J. H. Meson, Heckmondwike. *Chickens.*—First, T. Vickerman, Chickenley. Second, S. Schofield.
GAME (White and Piles).—First and Second, H. & C. Mason. *Chickens.*—First and Second, H. & C. Mason.
GAME (Black and Brassy-winged, except Greys).—First, G. Noble, Staincliffe. Second, J. Brook. *Chickens.*—First, J. Brook. Second, G. Noble.
GAME COCK—First, J. Hill & Sons, Drighlington. Second, Miss E. Beldon.
BANTAMS (Black).—First, J. Dixon. Second, S. Schofield, Heckmondwike.
BANTAMS (White).—First, J. Dixon. Second, S. Schofield.
BANTAMS (Gold and Silver-laced).—First, J. Dixon. Second, E. Beldon.
BANTAMS (Game).—First, G. Noble. Second, T. Vickerman.
BEST COCK AND TWO HENS NOT MENTIONED IN THE ABOVE CLASSES.—*Black Hamburgs.*—First, J. Dixon. Second, Miss E. Beldon. *Chickens.*—First, E. Leech, Greave House, Rochdale. Second, S. Schofield.
SWEETSTAKES.—*Game.*—First, H. & C. Mason. Second, T. Vickerman.
Bantam.—First, T. Vickerman. Second, Wallace & Oldroyd, Dewsbury.
Ducks (Aylesbury).—Prize, E. Leech. *Rouen.*—First, J. Dixon. Second, E. Leech.
PIGEONS.—*Pouters.*—Prize, Miss E. Beldon. *Carriers.*—First, J. Firth, Dewsbury. Second, — Hughes, Leeds. *Tumblers* (Almond).—First, Miss E. Beldon. Second, — Hughes. *Tumblers* (Any other variety).—First, Miss E. Beldon. Second, — Hughes. *Turbits.*—First, Miss E. Beldon. Second, — Hughes. *Jacobins.*—First, — Hughes. Second, G. J. Breary; M. Spedding. *Trumpeters.*—First, Miss E. Beldon. Second, S. Robson, Brotherton. *Orls.*—First, Miss E. Beldon. Second, J. Firth. Highly Commended, — Hughes. *Barbs.*—Prize, Miss E. Beldon. *Fantails.*—First, Miss E. Beldon. Second, J. Firth. *Nuns.*—First, Miss E. Beldon. Second, — Hughes. *Common Pigeons.*—First, G. J. Breary, M. Spedding. Second, J. Knowles, Dewsbury. *Any other variety.*—First, Miss E. Beldon, Second, J. Wade.
RABBIT.—*Long-Eared.*—First, C. A. Ridgeway, Dewsbury. Second, G. Haggard, Dewsbury. *For Colour.*—First and Second, L. Brook, Gomersal. *For Weight.*—Prize, C. A. Ridgeway.

PRESENT VALUE OF COCHIN FOWLS.

If anything were wanting in proof that good Cochin fowls are still very highly valued by poultry-breeders, and, if carefully bred, are a most productive source of profit, the following list of the sum produced already in this single season, from one gentleman's stud, would give conclusive evidence that the so-called "Cochin mania" is not to be altogether considered as a bygone, nor to be regarded as an unproductive folly. The facts, as handed to us by the owner himself, he has verified by the offer of reference to the purchasers of each lot if required. In short, he solicits investigation:—

LIST.		"PARTRIDGE-COLOURED."	
"BUFFS."	£ s. d.	1 cock and 2 hens.....	13 13 0
1 cock	21 0 0	1 ditto	12 12 0
1 cock and 2 hens.....	21 0 0	1 cock.....	6 6 0
1 cock and 3 hens.....	20 0 0	1 hen.....	5 5 0
1 cock and 2 hens.....	10 10 0	Partridge chickens (1863).	12 12 6
11 chickens (three months, 1863)	11 11 0	Total	50 8 0
4 pullets (Birmingham Show, 1862)	10 10 0	"WHITE."	
2 pullets, 1st Birmingham, claimed at.....	4 4 0	1 pen, cock and 2 hens.....	8 8 0
Total	98 15 0	1 ditto	5 5 0
		1 ditto	4 4 0
		2 hens	4 0 0
		Total	21 17 0

"The above birds have been sold for the *bona fide* prices quoted, besides upwards of £40 worth at lower prices, from my own yards alone at and since the Birmingham Show, 1862.—CHAS. FELTON, Erdington."

CHILLED EGGS.

I MUST apologise for again troubling you; but as some of your readers may still doubt my statements about eggs hatching after being cold, I have another example to offer. On the 27th July, 1863, nine Cochin-China eggs were put

under a hen, which my man placed in a secure spot to sit, although not exactly suited to my views, but I let him have his way. However, the hen after a few days objected to sit by compulsion, and he came with a long face to inform me on the 6th of August, that she would not sit, and the eggs were cold. I found them quite cold and very dirty, having been trampled on. I took them and washed them, and put them under a Cochin hen. Some of the eggs (three), being added, I threw them away, and to-day three chickens were hatched from the other eggs; one chicken in another evidently dead a long time, and the other eggs clear. I had no hopes of hatching any, and had it not been for the experiment would have thrown them away. They must have been cold twenty-four hours, and they hatched one day late only. They were wetted by myself several times and hatched strong chickens; the weather being about the same as an English summer, and the hen sitting in a barrel on its side with the end open. I think this proves, as I have done before, that it is worth while to continue sitting eggs that have been chilled even when cold.—F. C. HASSARD.

HALIFAX AND CALDER VALE AGRICULTURAL SHOW.

THE twenty-fifth annual Exhibition of the Halifax and Calder Vale Agricultural Association took place on Saturday the 29th ultimo (by the kind permission of Joshua Appleyard, Esq.), in Clare Hall Park, Halifax. The reputation that this annual gathering has had of being one of the most attractive in the north of England, was fully borne out this year by the character of the Show. The weather being most propitious, no less than 12,000 visitors, who paid £310 for admission, were present. The Show comprised Cattle, Horses, Dogs, Pigs, Poultry, Pigeons, Crops, Butter, Eggs, and implements, each department having its admirers. The arrangements of Mr. Irvine, the Secretary, were most complete, and admirably carried out. Poultry numbered 370 pens, and Pigeons 125.

Spanish headed the list, and were more numerous than usual in this neighbourhood. In adults the competition was not so close as in chickens. We were, however, completely at a loss to discover the superiority of the first over the second-prize pen. Some promising chickens were shown, but several of them were much trimmed.

Dorkings were well represented. In chickens, the Rev. J. F. Newton was first and second with good pens.

Cochins were numerous. In adults, Mr. Stretch and Mr. Dixon obtained first and second positions with Buffs, while Captain Heaton's Partridge were third; and although not in good condition, we thought the latter should have taken one step higher. In the chicken class Captain Heaton was first with a nice pen of Buffs, the cockerel rather leggy. The second prize was awarded to the same colour. Whites were third.

Brahmas were shown rather strongly, and contained many good specimens.

For *Single Game Cocks* there was an entry of eighteen, and, as might have been expected at this season, scarcely a bird in feather. The silver cup was awarded to Mr. Boyes, of Beverley, for a Black Red of superior quality, though rather faulty in head. Mr. Firth took second and third with a Brown Red and Black Red respectively, the latter appearing most unhappy at the close proximity of his neighbours. Three pens received high commendations, to which they were unquestionably entitled. A well-known successful exhibitor was represented by a single specimen, which, however, was unnoticed, except by inquirers who were at a loss to make out what colour the bird was intended to be. In single cockerels especial remark is unnecessary.

In the class for adult *Game*, good Black Reds were first and second, and Brown Reds third. Chickens were numerous, and of average quality. The prize adult Duckwings were good, and not equalled by the chickens. In "Any other Game," Mr. Adams's capital pen of Piles had to give place to indifferent Blacks; and in chickens splendid Piles belonging to the same exhibitor well deserved their first honours.

In *Polands* most of the best birds were completely out of feather. Silvers took first in both adults and chickens, and White-crested Blacks second.

Gold-pencilled *Hamburghs* formed fair classes, including some promising chickens. In Silver-pencilled *Hamburghs* some of the exhibitors were rather perplexed to find the first prize awarded to a pen without any pretension to "get up," with respect to colour and white ear-lobe, more particularly in the cock. In chickens, Mr. Dixon exhibited the best cockerel we have seen this year. Golden-spangled *Hamburghs* were much out of feather, and we fancied the prizes might have been reversed without being much from the mark. The chickens were good. In adult Silver-spangled *Hamburghs* Miss Beldon stood aloof of all competition. The chickens were a fair lot. Black *Hamburghs* formed nice classes.

In "Any other distinct breed" in adults, Mr. Dawson once more put in an appearance with his wonderful *Sultans*, taking first; Malays obtaining the other prizes. In chickens, Chinese *Silbies* were first, and *Crève Coeurs* second.

Game *Bantams* were exhibited in greater numbers than quality. A smart pen of white-legged Black Reds were first; Brown Reds second. *Selbights* were an average class; Silver-laced first and second; and Gold-laced third. "Any other variety" *Bantams* were a poor lot. Whites first; Blacks second; and a combination of both colours third.

Aylesbury Ducks were capital, Mr. Fowler only receiving second and third awards. In Rouens, Mr. S. Shaw's yard maintained its superiority in a very good class; and in "Any other variety" of Ducks, the first and third prizes were taken by the same exhibitor for splendid *Carolinas* and *Pintails*; *Mandarins* being second.

Geese and *Turkeys* were well represented.

The show of *Pigeons* formed not the least attractive feature of the Exhibition, which can be easily understood when the names of Messrs. Eden, Shaw, and Beldon, a host in themselves, were included in the list of exhibitors. The Powder classes were well filled. In that for single cocks, Mr. Eden was first with a splendid White; and Mr. Smith second, with a very superior Blue. For hens, Mr. Eden carried off both prizes with Whites of great length and admirable shape. In Carriers, Mr. Eden obtained three out of the four prizes; Miss Beldon taking first with her well-known *Dun hen*. The same exhibitors maintained their respective positions in *Almonds*. The Mottled Tumblers were excellent, more especially the first-prize pen; while in *Balds* or *Beards*, Mr. Shaw was first and second with *Blue Beards* and *Silver Balds*. The Owl prizes were awarded to fair Whites well shown. In *Turbits*, the first prize fell to Blues in good condition, rather coarse and uneven in crest; capital Reds taking second. Mr. Shaw had it all his own way in *Jacobins* with his famed Reds. *Fantails* were good, the prize birds being in excellent condition. The Barbs were unusually meritorious. Mr. Eden's magnificent *Yellows* were first; while his Blacks received high commendations. Mr. Shaw was second with the latter colour. *Dragons* were an excellent class: very fine Blues won, and changed ownership at the price of three guineas. The Trumpeter class was scarcely so good as might have been expected, Mr. Shaw's wonderful Mottles not having been sent. Miss Beldon was first with good Mottles; Blacks being second. In "Any other breed," Black Spots were first and excellent; Black-head Nuns second.

The Society's silver cup for the largest number of Pigeon prizes, or rather points, a first prize counting two, and a second one point, fell to the lot of Mr. Eden.

SPANISH.—First, J. Siddall, Halifax. Second, Miss E. Beldon, Gilstead, Bingley. Third, R. M. Stark, Hull. Commended, J. Dixon, Bradford; T. Greenwood, Eastfield House, Denbury. *Chickens*.—First, T. Greenwood. Second, J. Siddall. Third, Miss E. Beldon.

DORMINGS.—First, E. Smith, Middleton. Second, Miss E. Beldon, Bingley. Third, R. M. Stark, Hull. Commended, Rev. J. F. Newton, Kirby-in-Cleveland. *Chickens*.—First and Second, Rev. J. F. Newton. Third, H. Crossley, Broomfield. Commended, S. Pickard, Wakefield; J. Hargreaves, Skipton.

COCHIN-CHINA.—First, T. Stretch, Orm-kirk (Buff). Second, J. Dixon, Bradford (Buff). Third, Capt. Heaton, Manchester (Partridge). Commended, J. Firth, Halifax. *Chickens*.—First, Capt. Heaton, Manchester (Buff). Second, W. Dawson, Mirfield (Buff). Third, M. Mahoney, Bingley (White). Commended, Capt. Heaton.

BRABMA POOTRA.—First and Third, H. Lacy, Hebden Bridge. Second, J. Pines, Chertsey. *Chickens*.—First, S. W. Tinker, Huddersfield. Second, C. Lister, Mirfield. Third, H. Lacy. Highly Commended, S. W. Tinker.

GAME.—Cock (Any age or colour).—Cap. W. Boyce, Beverley (Black Red). Second and Third, J. Firth, Ellens Grove (Brown and Black Red). Highly Commended, H. Snowden, Great Horton; H. Adams, Beverley; A. B. Dyas, Madely. *Cockerel*.—First, J. Firth (Black Red). Second, T. Dyson, Halifax (not clear breast). Third, D. Jackson, Liversedge (Duck-

wing). Highly Commended, I. Wright, Ovenden. Commended, W. Bentley, Cleckheaton.

GAME (Black-breasted and other Red).—First, R. Adams, Beverley. Second, Miss E. Beldon, Bingley. Third, H. C. Mason, Leeds. Highly Commended, H. Crossley, Broomfield. Commended, J. Firth, Ellens Grove. *Chickens*.—First, I. Wright, Ovenden (Black Red). Second, J. Riley, Dewsbury. Third, J. Hodgson, Bradford. Highly Commended, J. Firth; R. Hemingway, Shelf; A. Hodgson, Illingworth. Commended, J. Spencer, Howarth.

GAME (Duckwing, Grey, and Blue).—First, H. Adams, Beverley. Second, Miss E. Beldon, Bingley. Third, H. Snowden, Great Horton. *Chickens*.—First, T. Dyson, Halifax. Second and Third, J. Firth, Ellens Grove.

GAME (Any other variety).—First, T. Hartley, Leeds (Black). Second and Third, H. Adams, Beverley (Piles). Highly Commended, H. C. Mason, Leeds. *Chickens*.—First, H. Adams, Beverley (Pile). Second, J. Hanson, Shelf (Pile). Third, G. Noble, Batley (Black). Highly Commended, W. Sutcliffe, Mytholmroyd.

FOLANES.—First and Third, J. Dixon, Bradford (Golden and Silver). Second, J. Smith, Keighley (Black). Highly Commended, Miss E. Beldon, Bingley (Silver). *Chickens*.—First, W. Newsome, Bingley (Silver). Second, J. Smith (Black). Third, J. Dixon (Black). Highly Commended, J. Dixon.

HAMBURGUS (Golden-pencilled).—First, S. Smith, Northowram. Second, A. M. Higgin, Burnley. Third, Mrs. M. Hemingway, Shelf. Highly Commended, Miss E. Beldon, Bingley. *Chickens*.—First and Third, S. Briggs, Holywell Green. Second, J. Firth, Halifax. Highly Commended, S. Smith.

HAMBURGUS (Silver-pencilled).—First, S. Briggs, Holywell Green. Second, Miss E. Beldon, Bingley. Third, S. Fielding, Middleton. Highly Commended, J. Dixon, Bradford. *Chickens*.—First, J. Dixon. Second, Miss E. Beldon. Third, S. Fielding. Highly Commended, E. Gill, Bingley.

HAMBURGUS (Golden-spangled).—First, J. Newton, Silsden. Second, Miss E. Beldon, Bingley. Third, N. Marlor, Manchester. Highly Commended, J. Ellis, Leeds. *Chickens*.—First, N. Marlor. Second, J. Ellis. Third, J. Dixon, Bradford. Highly Commended, Miss E. Beldon.

HAMBURGUS (Silver-spangled).—First and second, Miss E. Beldon, Bingley. Third, J. Dixon, Bradford. Highly Commended, F. W. Earle, Prescott; A. Newton, Silsden. *Chickens*.—First, Mrs. H. Sharp, Bradford. Second, S. Briggs, Holywell Green. Third, W. Sagar, Shipley.

HAMBURGUS (Black, white, or any other variety).—First, H. Adams, Beverley. Second, R. H. Nicholas, Newport, Monmouthshire. Third, S. Briggs, Holywell Green. *Chickens*.—First and Second, J. Dixon, Bradford. Third, J. Spencer, Howarth. Highly Commended, S. Briggs. Commended, S. Briggs.

ANY OTHER DISTINCT BREED (except *Bantams*).—First, W. Dawson, Mirfield (Sultans). Second, Miss E. Beldon, Bingley (Malay). Third, J. Dixon, Bradford (Malay). *Chickens*.—First, G. H. Greenwood, Lower Saltonstall (Sultan). Second, W. Dawson, Mirfield (Crève Coeurs). Third, Rev. W. Sturz, Daventry (Antwerp).

BANTAMS (Game).—First, Mrs. Noble, Staincliffe, Batley (Black Red). Second, I. Thornton, Heckmondwike. Third, E. Brown, Sheffield.

BANTAMS (Sulphur, Gold or Silver-laced).—First, Miss E. Beldon, Bingley (Silver). Second, W. H. Rawson, jun., Mill House (Silver). Third, J. Dixon, Bradford (Gold).

BANTAMS (Any other variety).—First, S. Schofield, Heckmondwike (White). Second, J. Gerner, Bradford (Black). Third, C. Walker, Halifax.

DUCKS (*Aylesbury*).—First, E. Leech, Rochdale. Second and Third, J. K. Fowler, Aylesbury. Highly Commended, T. E. Kell, Wetherby. Commended, R. M. Stark, Hull.

DUCKS (*Rouen*).—First, S. Briggs, Holywell Green. Second and Third, J. Dixon, Bradford. Highly Commended, S. Pickard, Wakefield.

DUCKS (Any other variety).—First and Third, S. Briggs, Holywell Green (*Carolina* and *Pintail*). Second, J. Dixon, Bradford (*Mandarins*). Highly Commended, F. W. Earle, Prescott (*Black East-Indian*). Commended, J. R. Jessop, Hull (*Black East-Indian*); J. Dixon (Grey Call).

GESE.—First, J. Dixon, Bradford (Toulouse). Second, W. Sugden, Brighouse (Emden). Third, H. Edwards, M.P., Eye Nest (Chinese).

TURKEYS.—First and Second, J. Dixon, Bradford (*American*). Third, E. C. Walker, Crow Nest. Commended, J. E. Norris, Brearley Hall.

EXTRA STOCK.—Highly Commended, H. Edwards, M.P., Eye Nest (Black Swans); W. Irvine, Ovenden (Buff Cochin-China pullets).

PLOVERS.—*Pouters* or *Croppers*.—First, P. Eden, Salford (White). Second, W. Smith, Beech Hill (Blue). Highly Commended, P. Eden; W. Smith. Commended, W. Smith. *Hen*.—First and Second, P. Eden, Salford (White). Commended, Miss E. Beldon, Bingley; E. Brown, St. Philip's Road, Sheffield. *Carriers*.—First and Second, P. Eden, Salford (Dun). Commended, Miss E. Beldon, Bingley; C. J. Samuels, Manchester.

Hen.—First, Miss E. Beldon, Bingley (Dun). Second, P. Eden, Salford (Black). Commended, P. Eden, Salford; J. Firth, Dewsbury. *Almond Tumblers*.—First, P. Eden. Second, Miss E. Beldon. Commended, P. Eden.

Mottled Tumblers.—First, P. Eden, Salford. Second, S. Shaw, Stainland. *Balds* or *Beards*.—First and Second, S. Shaw, Stainland (*Blue Beards* and *Silver Barbs*). *Owls*.—First, Miss E. Beldon (White). Second, H. Yardley, Birmingham (White). Commended, J. Firth, Dewsbury. *Turbits*.—First, H. Yardley (Blue). Second, S. Shaw (Red). Commended, S. Shaw.

Jacobins.—First and Second, S. Shaw (Red). *Fantails*.—First, T. C. Taylor, Middlesborough. Second, Miss E. Beldon. *Barbs*.—First, P. Eden (Yellow). Second, S. Shaw (Black). Highly Commended, P. Eden. Commended, S. Shaw. *Dragons*.—First, Miss E. Beldon (Blue). Second, J. Nelson, Ovenden. Highly Commended, A. Whitaker, Ovenden. *Trumpeters*.—First, Miss E. Beldon (Black Mottled). Second, S. Shaw (Black).

Maggies.—First, J. Wade, Leeds (Yellow). Second, S. Shaw (Black). *Any other breed*.—First, S. Shaw (Black Spot). Second, Miss E. Beldon (Nuns). Highly Commended, S. Shaw.

JUDGES.—*Poultry*.—Mr. Baxter, Elslack, Skipton; Mr. J. H. Smith, Skelton Grange, York; and Mr. P. Eden, Manchester. *Pigeons*.—Mr. Harrison Weir, London; and Mr. Thompson, Southowram.

WHITWORTH AND ROCHDALE AGRICULTURAL SOCIETY.—At the ninth annual meeting and exhibition of this Association held on the 19th ult., Mr. John Wrigley, reed-maker, of Wardleworth Brow, exhibited two glass bee-hives, which

afforded an excellent opportunity to the observer of witnessing the operations of the busy occupants inside, their attention to the queen, and the movements of that royal personage while she deposited her eggs, with a full insight into the domestic life of these little insects, whose industry is only equalled by the ingenuity displayed in the internal construction of their honey-laden home.—(*Rochdale Observer*.)

WAKEFIELD POULTRY SHOW.

THE second annual Exhibition of the Wakefield Poultry Society took place at Wakefield on Wednesday last, the 2nd inst. The number of poultry was not large, but many excellent birds were shown.

Game were divided into classes of adults and chickens respectively, for Black-breasted and other Reds and Duckwings; while a class was allotted for Game and other variety of any age. In old Birds good Black Reds won. In *Duckwings* the first-prize pen would have appeared to more advantage had the legs of the birds matched in colour. Blacks secured the remaining prizes. The chickens were, as a lot, inferior to the old birds. *Spanish* were good; Miss Beldon, however, having an easy victory in adults. In adult *Cochins* Buffs were first and Whites second. In chickens Partridge took first position and Buffs second. *Dorkings* formed a nice lot; some of the prize birds were of great excellence. *Hamburghs* were good. Miss Beldon and Mr. Dixon carried off most of the prizes. The first-prize pen of Silver-pencilled chickens contained a splendid pair of pullets. *Polands* were good: White-Crested Blacks first. In *Any other Breed* Mr. Dawson's Sultans won in adults; and in chickens Black Hamburghs obtained first prize. *Bantams* were of average merit. Mr. Harrison exhibited fine Whites rather deficient in feather. The silver medal for the best pen of Bantams was awarded to Black Red Game in the same condition. Some well-known capital Blacks, though entered, were absent. Silver-laced were fairly represented.

The show of *Pigeons* was excellent; chiefly, however, noticeable for the reversal of many of the Halifax decisions of the previous week, and for the introduction of a new feature in the exhibition of Barbs. In this class the first prize was awarded to a pen of Blacks with the wattle round the eye of the most exquisite magenta. A visitor, more curious than we imagine would have been agreeable to their owner—a chemist, we believe—instantly succeeded in removing the whole of this beautiful colour from an eye of one bird, contrasting the eye in its natural state with the supposed improvement. In *Fantails* crested birds took first, while in *Turbits* an indifferent pair of plain-headed Yellows gained that honour.

The following is the list of prizes:—

GAME (Black-breasted and other Reds).—First, F. Sales, Crowle, Lincolnshire. Second, Miss E. Beldon, Bradford. *CHICKENS*.—First, T. Vickerman. Second, J. Hodgson, Bradford. Highly Commended, Miss E. Beldon.

GAME (Duckwing and other Greys and Blues).—First, J. Fell, Drighlington. Second, T. Vickerman. *CHICKENS*.—First, T. Vickerman. Second, J. Fell. Highly Commended, J. Hodgson.

ANY OTHER VARIETY.—First, G. Hartley, Gomersal. Second, G. Noble, Heckmondwike.

SPANISH.—First, Miss E. Beldon. Second, T. Burch, Sheffield. Highly Commended, J. Dixon, Bradford. *CHICKENS*.—First, S. Robson. Second, T. Greenwood. Highly Commended, J. Sidal, Halifax; S. Senior, Dewsbury; W. Newsome, Bingley.

COCHIN-CHINA.—First, H. & G. Newton, Garforth, Leeds. Second, W. Dawson, Hopton, Mirfield. Highly Commended, E. Smith, Manchester; R. White, Sheffield. *CHICKENS*.—First, E. Smith. Second, W. Dawson. Highly Commended, R. White.

DORKING.—First, H. Himsforth, Wakefield. Second, J. Dixon, Bradford. Highly Commended, Miss E. Beldon. *CHICKENS*.—First, T. E. Kell, Wetherby. Second, Rev. J. F. Newton, Kirby-in-Cleveland. Highly Commended, J. Hirst, Wakefield; W. Newsome.

HAMBURGHS (Golden-spangled).—First, Miss E. Beldon. Second, C. W. Brierley, Rochdale. Highly Commended, J. Dixon, Bradford; T. Burch. *CHICKENS*.—First, Miss E. Beldon. Second, T. Burch. Highly Commended, J. Dixon.

HAMBURGHS (Silver-spangled).—First, Miss E. Beldon. Second, J. Dixon. Highly Commended, H. Carter. *CHICKENS*.—First, J. Dixon. Second, N. Nicholas, Manchester. Highly Commended, Miss E. Beldon.

HAMBURGHS (Golden-pencilled).—First, S. Smith, Northowram. Second, Miss E. Beldon. Highly Commended, J. Dixon. *CHICKENS*.—First, J. Dixon. Second, Miss E. Beldon. Highly Commended, S. Smith.

HAMBURGHS (Silver-pencilled).—First, Miss E. Beldon. Second, J. Dixon. Highly Commended, T. Vickerman. *CHICKENS*.—First, D. Hingworth. Second, H. Pickles, Jun. Highly Commended, J. Dixon.

POLANDS (Any variety).—First, Miss E. Beldon, White-crested Black. Second, J. Dixon, Silver. Highly Commended, H. Carter; W. Newsome. *CHICKENS*.—First and Second, J. Dixon.

ANY BREED NOT BEFORE NAMED.—First, W. Dawson. Second, J. Dixon. Highly Commended, H. & G. Newton. *CHICKENS*.—First, Miss E. Beldon. Second, R. Thompson, Keadal.

BANTAMS, Black-breasted and other Reds.—Silver Medal and First, T. Vickerman. Second, G. Noble. Highly Commended, J. G. Pearson, Whitechurch, Salop; — Harrison, Wakefield.

BANTAMS, Duckwing.—First, W. Lawrenson, Allestree, Derby. Second, Master C. Crosland.

BANTAMS, White.—First, — Harrison, Wakefield. Second, J. Dixon. Highly Commended, T. Vickerman.

BANTAMS, Black.—First, J. Dixon. Second, S. Schofield.

BANTAMS, Golden or Silver-Laced.—First, J. Dixon. Second, Miss E. Beldon. Highly Commended, G. Malpas, Jun., Wavertree, Liverpool; E. Yeardley.

BANTAM COCKS, Game.—First and Second, Master C. Crosland.

DUCKS.—Prize, J. Hirst.

PIGEONS.—*Carriers*.—First, H. Yardley. Second, J. Firth, Webster Hill, Halifax. *Pouters*.—First, S. Robson. Second, H. Yardley, Birmingham.

Highly Commended, Miss E. Beldon. *Tumblers*, Almond.—First, H. Yardley. Second, Miss E. Beldon. *Tumblers*, Any other variety.—First, W. Carlton. Second, Miss E. Beldon. *Barbs*.—First, T. D. Walker, Magenta eye. Second, H. Yardley. *Jacobins*.—Prize, F. Key, Beverley.

Trumpeters.—First, S. Robson. Second, Miss E. Beldon. Highly Commended, K. Key. *Owls*.—First, H. Yardley. Second, Miss E. Beldon.

Turbits.—First, M. E. Jobling, Plain-headed. Second, Miss E. Beldon. *Fantails*.—First, H. Yardley. Second, J. W. Edge, Crested. *Nuns*.—First, Miss E. Beldon. Second, J. W. Edge. Any variety not mentioned.

—First, H. Yardley. Second, J. W. Edge. Highly Commended, T. D. Walker; Miss E. Beldon.

The Judges were—for *Poultry*, Mr. Nathan Marlor, Denton, Manchester; and Mr. Jackson, York. For *Pigeons*, Mr. G. Robson, Hull.

COTTINGHAM POULTRY SHOW.

THE annual Exhibition of poultry in connection with the Floral and Horticultural Society's Show, was held at Cottingham on Wednesday, September 2nd, in a field kindly lent for the occasion by Mrs. Gee. Rain fell rather copiously during the previous night, and throughout the morning heavy threatening clouds often obscured the sky; but thanks to the high winds which prevailed during the day, they were driven onwards to some less-favoured locality, and the pleasure-seekers in connection with this Show had fair weather with occasional outbreaks of sunshine, which enabled them to enjoy the goodly sight. Bands of music gave forth their melody, and a large concourse of visitors enlivened the scene.

Some very excellent birds were shown in the Various classes, and in some there was strong competition, about 250 pens being entered; the fanciers of the district being well represented in both poultry and Pigeons. Subjoined is a list of the awards:—

SPANISH.—First, G. Pashley, Hull. Second, R. M. Stark, Hull. Highly Commended, O. A. Young, Driffield. *CHICKENS*.—First, R. M. Stark. Second, J. Holmes, North Cave. Highly Commended, Mrs. Ward, North Cliff.

DORKINGS.—First, R. M. Stark. Second, O. A. Young. Highly Commended, R. M. Stark. *CHICKENS*.—First, H. Elvidge, Leven Carr. Second, W. Watson, Bishop Burton. Highly Commended, O. A. Young.

COCHIN-CHINA (Black or White).—First, D. Bromley, Cottingham. Second, R. Loft, Woodmansey. *CHICKENS*.—First and Second, W. Maynard, Ganton.

COCHIN-CHINA (Any other variety).—First, R. Clark, South Dalton. Second, T. C. Trotter, Sutton. *CHICKENS*.—First, H. Taylor, Newland. Second, T. C. Trotter.

GAME (Black-breasted).—First, J. Hodgkinson, Hull. Second, H. Adams, Beverley. Highly Commended, H. Adams. *CHICKENS*.—First, W. Burgess. Second, H. Adams. Highly Commended, H. Adams.

GAME (Any other variety).—First and Second, H. Adams. *CHICKENS*.—First and Second, H. Adams. (Whole class Highly Commended.)

POLANDS.—First, J. Stephenson, Preston. Second, R. Loft. *CHICKENS*.—First and Second, R. Loft.

HAMBURGHS (Golden-spangled).—First, J. Blanshard, Driffield. Second, G. Holmes, Driffield. *CHICKENS*.—First and Second, J. Murgatroyd, Bishop Burton.

HAMBURGHS (Silver-spangled).—First and Second, S. Campling, Cottingham. *CHICKENS*.—First and Second, S. Campling.

HAMBURGHS (Golden-pencilled).—First, W. Gofton, Driffield. Second, G. Pashley. *CHICKENS*.—First, J. Bilton, Cottingham. Second, W. Gofton.

HAMBURGHS (Silver-pencilled).—First, T. C. Trotter. Second, J. Bilton. *CHICKENS*.—First and Second, S. A. & J. Faulkner, Hunsanby.

BANTAMS (Gold-laced).—First, O. A. Young. Second, R. M. Stark. *CHICKENS*.—First W. Gofton. Second, R. Green, Brantingham.

BANTAMS (Game).—First, R. M. Stark. Second, J. R. Jessop, Hull. Highly Commended, J. Cranidge. *CHICKENS*.—First, G. Holme. Second, W. Gofton.

BANTAMS (Any other variety).—First and Second, R. M. Stark (Silver-laced and Black). *CHICKENS*.—First, G. Pashley (White). Second, E. Carling, Cottingham.

ANY DISTINCT VARIETY.—First, H. Adams (Black Hamburghs). Second, O. A. Young (Malays). Highly Commended, J. Pares, Chertsey; E. Proctor. *CHICKENS*.—First, J. Pares (Brahmas). Second, O. A. Young.

FAMLYARD CROSS.—First, Mrs. White, Thearne. Second, R. Goulden, Bridlington. *CHICKENS*.—First, G. Loft. Second, G. Bromley. Highly Commended, G. Bromley.

GAME COCK (Any age or colour).—First and Second, H. Adams. Third, J. Cranidge, Louth.

GUINIA FOWLS.—First, H. Merkin, Driffield. Second, J. R. Jessop.

TURNKEYS.—First, R. M. Stark. Second, O. A. Young.

GESE.—First, O. A. Young. Second, R. Voakes, Driffield. Highly Commended, O. A. Young.

DUCKS (Aylesbury).—First, R. M. Stark. Second, O. A. Young.

Ducks (Rouen).—First, T. C. Trotter. Second, R. M. Stark. Highly Commended, R. M. Stark.

Ducks (Any other variety).—First, J. R. Jessop (East-Indian). Second, R. M. Stark (East-Indian). Highly Commended, R. Gowden, Bridlington. Figeons.—First, W. Watson, Beverley. Second, W. Witty, jun., Cottingham. Carriers.—First, W. Watson. Second, T. Ellington, Woodmansey. Trampeters.—First, F. They, Beverley. Second, H. Yardley, Birmingham. Jacobins.—First, J. R. Jessop. Second, T. Ellington. Highly Commended, T. Ellington. Fantails.—First, T. Ellington. Second, W. Watson. Highly Commended, J. R. Jessop. Tumblers.—First, F. They, Second, J. R. Jessop. Highly Commended, G. J. Pratt, Hull. Barb.—First, T. Ellington. Second, W. Witty, jun. Nuns.—First, F. They, Second, J. R. Jessop. Any other variety.—First, H. Yardley (Owls). Second, J. R. Jessop (Turbits). Highly Commended, F. Stathers. Rabbits.—First, G. Teal. Second, G. Loft.

The Judges were M. Hunter, Esq., Green Hamerton, near York, and F. Ferguson, Esq., Risby Park, near Beverley.

PRIZES AT THE LAST SHEFFIELD POULTRY SHOW.

"EXHIBITOR" inquired last week if the prizes at this Show were already paid, and in reply I can inform him they are not, nor do I think them likely to be. I wrote to the Secretary four times on the subject before I could get an answer, which all your readers will agree is very bad policy on the part of a manager of affairs. Being rather put out at receiving no answer after posting the third letter, I thought I would see what a fourth would do in rather strong terms. This immediately brought a supplicating letter as follows:—

"I deeply regret that your previous letters have been unanswered, but I have been from home about a month engaged on business, and the party who should have attended to the correspondence must have neglected it; and I am still further sorry to say, that owing to many difficulties thrown in the way of the Show by several members of last year's Exhibition Committee, it resulted in a total failure. This, added to the fact of my other speculations (before and since the Show), being singularly unfortunate, I am compelled to resort by pressure of my creditors to the Court of Bankruptcy to relieve me from my difficulties; and although I may be released from my debts, you may depend I shall feel it both a pleasure and a duty (should I at some future time attain a position to discharge your claim), to do so."

What is the proper epithet to apply to a man who takes everything upon his own responsibility, the financial department included, holds the Show, gives it out as a complete failure, pockets the entrance fees, &c., without paying a single farthing as prize-money, and takes himself out for a month or more on business, as he calls it?

Do you think there is any possibility of the money eventually being paid?

I hope this subject will not cease without a little discussion and investigation.—ALIAS EXHIBITOR.

[If there was any Committee for managing the Sheffield Poultry Show all its members are bound in honour, and may be in law, to pay the prizes awarded. If, on the other hand, as you say, the Secretary, now a bankrupt, "undertook everything," and the exhibitors accepted his sole responsibility, we agree with you that the prizes are "not likely to be paid;" but those entitled to them might prove as creditors against the bankrupt's estate.—EDS. J. OF H.]

BEE-KEEPING IN DEVON.—No. XXI.

A TRIP TO THE SEASIDE.

I've been to the seaside—

"O yes; I know," mentally interpolates the reader. "Bathing machines, bath chairs, perambulators, inopportune donkey-boys, circulating library, lots of children at the diggings, used-up dandies, ultra-fashionable young ladies in balloon skirts, pilfering landlady, bad cooking, and worse attendance."

Not a bit of it, my dear Sir or Madam. I've been to a little hamlet in the wilds of North Devon, nine miles from a market town, four miles from the butcher's, a couple of miles from a letter-box, and the same distance from church, perfectly free from the abominations you have recited, where we could do as we liked, and enjoy to the uttermost a fine open sea (Lundy Island in the distance, but beyond that the broad Atlantic with no land in a straight line nearer than

America), and an excellent beach. Oh! the delights of that happy time, when we lodged in the quaintest of farm-houses, with doorways and cross-beams in the ceilings that barely cleared one's head; bedroom doors made in the primitive fashion of three rough planks nailed to cross pieces at the top and bottom, and secured by a wooden latch, over which I stuck my penknife to guard against accidental intrusion. What shouts of laughter arose the first morning, when the children found themselves imprisoned by the misbehaviour of the only iron latch that our dormitories boasted, and were ultimately released by a vigorous application of the shoulder to the outside. What fun it was when, neglected by the butcher, and with no poultry immediately available, we were reduced to dine upon eggs and bacon fried to a turn by that excellent farmer's wife whose cookery was always perfection, and brought in hot and crisp by her buxom daughter, at once the most obliging and efficient of attendants. What jolly rides we had in the spring cart driven by the good-natured farmer himself, and drawn by his stalwart horse sixteen hands high and rising five years old, that would walk more than four miles an hour, and trot something like fourteen without a touch of the whip, which in fact his driver never carried. Not a little proud was he of this really fine animal, which had been bred by himself; nor was he ever tired of expatiating on his courage, fine temper, and manifold good qualities. Did we not ride in this way over Woodcombe Sands, three miles long, and listen with moistening eyes and bated breath whilst our conductor related how, two winters ago, nine stout ships failed to weather the *Morte* (angler, death) Rock at the entrance of the Bristol Channel, and all came ashore here and went to pieces in one fatal night, when eight out of their nine crews were drowned, with the exception of two men who alone survived to tell the tale? With what interest did we look at that gorse covert where, in almost the last stage of exhaustion, the master and sole survivor of his ship's crew dragged himself one dark night, and with nails torn off and fingers lacerated by clinging for dear life to those rugged rocks against which he had been hurled by the pitiless breakers, laid himself down in utter ignorance of his position until the grey light of dawn enabled him to crawl to a habitation some two or three miles inland. How surprised were we when on arriving at the little village of Morthoe we suddenly found ourselves in the midst of donkeys and civilisation in the shape of visitors from Hlacombe. Need I say that the children were rather impatient of the time we devoted to the examination of the ancient church recently restored by the munificence of the incumbent, and containing the remains and a monument to the memory of Tracey, one of the murderers of Thomas à Becket, by whom it was founded seven hundred years ago, or describe with what delight they scrambled on donkeyback, and set off down the hill to enjoy a gallop on the sands, and pick up shells at Barrycane? Then came a plunge into the sea and a battle with the breakers, resulting in a glorious swim outside, alternately litted on the top of a watery hill and then sinking into a dark green valley extending on either hand as far as the eye could reach, as we rose and fell with the long swell of the Atlantic.

"Now, Mr. Bee-keeper, this is all very well; but don't you know that Kingsley has described North Devon scenes and characters far better than you can ever hope to do? and that when you last went to the seaside you dwelt in stylish lodgings at a fashionable watering-place, where you visited and were visited by your bee-keeping friend who assumes the convivial initials, and that you declared you were very comfortable, and enjoyed it immensely? and don't you know what somebody says in that nasty Latin which I never could understand, something about a *knee* and a *svitor**, which I thought was very interesting to ladies, but which I am told means only that a cobbler should stick to his last? and so, of course, a bee-keeper should stick to his bees, for you know a parson should —"

Yes, yes, my dear Madam, I do know, and fully admit the justice of all that you would urge, but I am coming to the bees presently; and in the meantime you may allow me to tell in my own way how much we enjoyed ourselves, for I have a couple of keen Editors over my head with two pairs of sharp scissors in their hands, by one or the other of which

* *Ne sutor ultra crepidam*—Let not the cobbler go beyond his last.

the thread of my discourse will be cut short the moment they think it degenerating into twaddle. You will not, I am sure, object to my telling how the daughter of the rector was married during the first week of our sojourn, and that two of the young ladies of our party, whose curiosity led them to witness the ceremony, returned hot and tired from their walk, which turned out longer than they anticipated, but declared that the bride was beautiful, the bridesmaids charming, and the bridegroom a gentleman. On going to church the following Sunday, the aforesaid young ladies acted as pioneers, being supposed perfectly acquainted with the road; but as they outwalked their elders, we had to inquire the way, which resulted in our reaching the church before them; and it was not until the choir had done practising, and "Home, Sweet Home," had been played as a voluntary on the appearance of the clergyman, and the service was pretty well advanced, that they made their appearance, having lost much time in seeking us on the road they had taken, which had also the disadvantage of prolonging their walk to four miles instead of two.

And so the first week passed. THE JOURNAL OF HORTICULTURE, of course, duly arrived (could I have existed without it?), but I was in no humour for writing on bee matters. Even the expression of Mr. Lowe's "surprise" (will he ever forgive my treating his admonitions so irreverently?) at my "lamentable plaint," only moved me to laughter, and I fully enjoyed the joke of seeing his grave rebuke side by side by the article which pronounced my apiary to be "convalescent," and contained within itself, as I thought, sufficient evidence that my "undaunted spirit" had by no means deserted me.

During the second week the ruling spirit awoke within me, and I made the acquaintance of Mrs. S., wife of farmer S., who possessed three old stocks, from which had issued five swarms, making eight in all, which stood in a small garden in front of the house. At her request I "hefted" them one by one, and was astonished at their weight. With the exception of a very late swarm (and even this was nearly 20 lbs.), not one weighed so little as 40 lbs., and some were certainly above 50 lbs. After a little conversation I obtained permission to drive a swarm—a second swarm of this year—which, nevertheless, weighed above 50 lbs., and was so full of bees that large masses were clustered outside. Having to write to Exeter for bee-apparatus, the following Saturday morning was fixed for the operation, and in the meantime I raised the hive from its floor-board (certainly a misnomer for a slab of slate) on three stones, in the hope that the current of air thus produced would compel the out-lying bees to seek shelter within.

On presenting myself at the appointed time I was introduced to the worthy bee-master, who testified no small interest in my proceedings; but I was also rather disconcerted at finding nearly the whole adult population of the village assembled to witness an exploit of which they had never before heard, and as to the accomplishment of which they were evidently incredulous. Having inducted myself into a bee-dress, and placed a couple of spare ones at the service of the timid among the spectators, but of which none would avail themselves, I proceeded to business by exerting my utmost strength in steadily inverting the ponderous hive on a pail; but in doing this I became aware that the precaution I had taken of previously raising it had been of little avail, since the back and sides were still covered with clustering bees. Placing an empty hive over the full one, it became necessary to dislodge the outsiders before securing the two hives together with a cloth. This was quickly done by sweeping them off with a feather; but what an outcry arose among the spectators! shouts and screams were overborne by roars of laughter, and the fun became fast and furious as one by one rushed frantically into the house, followed by the shouts and laughter of their companions. Foremost and loudest in the enjoyment of the joke was Mr. S.'s father, who valorously kept the field after his descendant had beaten an ignominious retreat. His triumph was, however, of short duration, as I was soon made aware by the appearance of his son at the front door, gesticulating with delight, and exclaiming, "Feyther's a-sting'd! feyther's a-sting'd! He'th a got et at last!"

But when the confined bees had been conveyed into the back garden, and had been sufficiently subdued by con-

tinuous rapping to admit of my removing the cloth and raising one side of the empty hive—and when, uncovering my own face to encourage them, I invited the spectators to witness the ascent of the remaining bees, their astonishment was unbounded; and I believe one spoke the sentiments of the majority when he expressed his conviction that I had "a-charm'd 'em."

The anger of the out-lying bees in the front garden at being so unceremoniously dislodged was, however, by no means appeased. Steady cart-horses shook their heads as they approached the house, snorted wildly, and turning short round set off on a return trip at vastly accelerated speed, despite the loud and oft-repeated "Whoa's" of their distracted drivers. Whilst restoring the bees to their original position, but in an unfurnished dwelling, I saw a frantic shoemaker charge wildly down the hill fighting desperately with hat in hand in the vain endeavour to distance or keep at bay a score of winged assailants which plied their weapons without mercy. When cutting down the combs afterwards, Mrs. S. came in with the information that a sack of flour had been left at the door. "What d'y'e main?" said her husband. "I don't want no sack o' v'lour." The explanation was that the miller was passing on horseback with a sack of flour, when his horse took fright and incontinently deposited his load on the spot.

Altogether the driving of farmer S.'s bees was nothing less than a nine days' wonder, and it was declared on all hands that the inhabitants of the village of C— would long remember the visit and the exploits of—A DEVONSHIRE BEE-KEEPER.

UNITING BEES.

I AM a beginner in bee-keeping. I have five hives, four of them swarms that I mean to keep, one an old hive, dome-shaped, that I mean to rob. Will you tell me the best way of adding the bees of this hive to one of my others?

In looking over your back Numbers I see one of your correspondents recommends us by a smart blow to shake them out into the other hive. Not knowing the exact amount of smartness required, I am afraid of sending out combs and honey with one. Is it a safe operation? or is the tedious work of driving better? and which is the best time for it?—WYESIDE.

[The best mode of uniting bees in common hives is by driving in the middle of a fine day, as directed in "Bee-keeping for the Many" (page 59, new edition). You must have mistaken our correspondent's meaning, who doubtless referred to bees clustered in an unfurnished hive. A blow smart enough to dislodge the bees of an old stock with well-filled combs must, as you surmise, send combs and honey with them.]

EXPERIMENTING ON BEES AND FOUL BROOD.

I THINK there is not a reader of your valuable paper, that keeps bees, who is not very much indebted to "A DEVONSHIRE BEE-KEEPER" for the information he is so ready to give. Had it not been for his letters many bee-keepers would have lost their bees. The dwindling away of his apiary has nothing whatever to do with its being an experimental one, but has arisen from his introducing the disease to it. I think if his brother apiarists had lent their assistance in endeavouring to find out the cause, it would have been more like brother fanciers than to dilate on his misfortunes. His coming so freely forward and stating his loss will be the saving of many a hive of bees to other apiarists, for had it not been for his letters I should have lost the hive as stated in your paper of the 25th ult., and have also introduced the disease into my apiary.—A. W.

WAX MOTHS.

LAST September one of my strongest stocks of bees was observed to be in great commotion. The bees made almost as much noise as when they swarm, and multitudes of them came in at the open windows of the house to the great disturbance of the family.

About a month ago I lifted up the hive and found the entire comb reduced to a mass of decay, appearing almost like yellow moss. In the centre there was a large cone attached to the roof, of which I have broken off a piece, and forward it to you by this post. The top of the hive was also covered with single cocoons like those in the enclosed mass. Each appears to contain a grub, and the moth which I enclose was adhering dead to the side of the hive. It appears to me (who have very little knowledge of these things), to be one that has come forth from the chrysalis, but that never has flown.—S. E.

[This inquiry reached us in March last, but none of the moths came to perfection until the 30th July. They turn out to be *Galleria mellonella* (Linnaeus), probably the worst kind of wax moth, and appear, as far as we can judge by the illustrations in Mr. Langstroth's work, to be identical with the species which is so much dreaded by American apiarians. The male is the *G. cereana* of Linnaeus, *G. cereola* of Guénéé, and is smaller than the females, which also it outnumbers by about twenty to one. Fortunately it is scarce in this country, and the mass of cocoons you sent have proved quite a boon to all the entomologists in our neighbourhood.]

A NEW AND SUPERIOR MATERIAL FOR HIVE-MAKING.

ONE consequence of my trip to north Devon, the incidents of which have been already described, is the discovery of a new material for hive-making, which promises the best results. It is *Elymus arenarius*, or Upright Sea Lyme Grass, which grows plentifully on the sand-hills in many parts of our coasts, and the principal use of which is to bind sand-banks so as to prevent encroachments of the sea, and keep the sand itself from drifting during high winds. The dwellers on the north coast of Devon have also applied it to the manufacture of a cheap kind of broom, as well as a substitute for straw in hive-making. Being informed that hives fabricated of this material were much neater than, and lasted thrice as long as, those made of straw, I purchased and brought away with me a sufficient quantity for a Woodbury frame-hive. This I have placed in the hands of Messrs. Neighbour & Sons' hive-maker, who eulogises it most highly; and if it at all equals his expectations, the apiarian world may hereafter rejoice in the fact that the cottagers of north Devon, although much behind the rest of us in many respects, were yet able to afford a valuable hint to—A DEVONSHIRE BEE-KEEPER.

FOUL BROOD PRODUCED BY FEEDING BEES WITH FOREIGN HONEY.

I WAS sorry to see the report in THE JOURNAL OF HORTICULTURE, of July 21st and 28th, of "A DEVONSHIRE BEE-KEEPER'S" apiary suffering from foul brood, and am afraid I have not yet found out the right cause. I have been a bee-keeper now some thirty years, and have only known one case of foul brood from English honey. It was a hive which had been sent to the moors and came back about 60 lbs. weight, when the owner set it up for winter stock. The following spring the bees did not appear to increase, but gradually dwindled away, and when the bee-keeper came to examine his hive he found the combs and honey cankered, and disagreeable in smell.

I will give my own experience. About twelve years ago I bought a quantity of foreign honey for myself and friend. I gave to one of my stocks a quantity of the honey just as it was, and the following spring the bees commenced working as usual; but still they never increased, and, besides, I perceived some of the bees crept out and died. So I turned up the stock and examined it. The combs were partly covered with a brown substance, and the smell from it was most offensive. Besides this, the combs were nearly rotten, and the few bees left were crawling about, poisoned with the honey and foul smell. The honey I sold to my friend he boiled away with lump sugar, and the following spring part of his bees died, but towards the latter end of April they partially recovered their strength, but were not as good

hives as they ought to have been at that season. Both my friend and myself laid the blame at the time to the foreign honey, as my hives, which had all honey given them, dwindled completely away, whilst his which had only part honey mixed with sugar, recovered after losing part of their bees. If "A DEVONSHIRE BEE-KEEPER" has fed his bees with foreign honey, I should say that is the cause of the disease. I merely suggest this from my own experience, and I have never used foreign honey since.—C. B. H.

[This narrative confirms the correctness of German apiarians, who state that foul brood is usually produced by feeding bees with imported honey. In my own case, however, I have no reason to believe that it had anything to do with the misfortune, since, although I used a portion of foreign honey, I parted with some of it to my friends, Messrs. S. B. and George Fox, in neither of whose apiaries were any evil effects produced by its use.—A DEVONSHIRE BEE-KEEPER.]

BEES IN CUMBERLAND.

PERHAPS a short account of apiarian doings in Cumberland may be interesting, and I will, therefore, write a few lines upon the subject if you think them worthy of publication.

In the first place, I may say that it has been generally considered a very favourable season, although swarms were not so early this year as last. The first that I heard of was on the 30th of May, and during the first week in June they were frequent; and for numbers a very old bee-keeper assured me he never knew such a season, he having a top swarm which swarmed four times, two of which swarms he lost. Another individual has a hive which has swarmed seven times since the 19th of June last, all of which swarms he secured; and another person has a hive which swarmed twice in one day. So much for swarming.

I have watched with interest the progress of the Ligurian species, and rejoice to hear that they have acquitted themselves so well; but I think they must not be allowed to carry off all the honour and glory. An old friend of mine who has been a successful bee-keeper with the cottage straw hive, although knowing little about bees scientifically (calling the queen "the Maister Bee"), took from a hive a top swarm lately, which weighed 8 stone 2 lbs., and a top he took off the same hive before weighed 8 lbs. That, I think, the Ligurians will find it difficult to exceed. I have often thought that the elevation of the bee-stand has a considerable influence upon their successful swarming. If too high they are apt to fly away, and if on the level they are very slow in swarming. A gentle elevation I think answers best. A few hives under my own care stand low, and the swarming was so tedious that I have practised artificial swarming for the last ten years by driving, and always with success. I only once failed in driving the queen at the first operation—five minutes I find sufficient time to drive. A bee-dress or gloves I never think of. A few puffs of smoke from a puff-ball keep them quiet.

With regard to family affairs, I have kept them quite dark; but, if it be true that Huber heard them speaking the French language, some of your readers that speak French might inquire if they are at all sensitive upon the subject.—A FRIEND OF THE BEE.

OUR LETTER BOX.

SHEFFIELD POULTRY SHOW.—In reply to "EXHIBITOR," R. H. Nicholas and T. Davies, of Newport, Monmouthshire, beg to state that they have not received their prize money from the late Show.

RABBITS KILLING THEIR YOUNG (*F. M. Parkes*).—The only cure is to kill the infanticide.

TAKING HONEY—HUMBLE BEES (*A. G.*).—Honey may be taken as soon as the honey-harvest is over, but this varies very much in different localities. In some districts all increase ceases in July, whilst in others it continues till October. The bees you have purchased belong to the only species of hive bee indigenous to Britain. The large, heavy, black-velvety bees you describe are a species of wild humble bee, the females of which alone survive the winter. They do not store honey like the hive bee, and their natural history precludes their being domesticated in the same manner.

WORK ON BEES (*Not an Old Subscriber*).—You will find all hives worth notice described, and many depicted, in the fifth edition of "Bee-keeping for the Many," just published at our office. You can have it free by post for six penny postage stamps. All communications to our departmental writers must be in the pages of our Journal.

SQUIRRELS (—).—You will find an article on the subject in our next Number.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 66.9°, and its night temperature 45.7°. The greatest heat was 84°, on the 17th 1843; and the lowest cold, 29°, on the 17th, 1840. The greatest fall of rain was 0.90 inch.

AMARANTHUS MELANCHOLICUS RUBER AND COLEUS VERSCHAFFELTI.

APID though the increase of plants has been which the enterprise of collectors sent to distant lands has placed within our reach, and notwithstanding the many improvements which the hybridisers of the present day have effected in bedding plants, it is questionable whether the plants cultivated in the most fashionable flower gardens of the present time present so large an array of names as similar lists did fifteen years ago; for the yearly additions are counterbalanced by corresponding weedings-out. Probably in many instances the latter work has exceeded the former, so as to leave fewer names on the flower-garden list than existed before variegated plants became such an important feature; or before the Cuphea and more recent introductions found their way into general use. That successive

weedings-out are wanted there can be no doubt; and some go to great extremes in this respect; while others, anxious as much to retain a collection as to produce an effect, preserve a longer list of names. There are, however, plants which have gone out of fashion through the current of public opinion having set in against them, and this latter class is every year receiving fresh accessions, often from plants that have scarcely had a fair trial.

So fastidious have our flower-gardening connoisseurs become of late, that it is not an easy matter to please them now. The properties possessed by a plant are far more carefully examined than years ago. To be a favourite in the flower garden now it is requisite that a plant be ornamental from June until November, no lack of servitude during that period being permitted. A freedom but not rankness in growth is also required, as well as sufficient hardiness to withstand cold winds, and many other points of merit. This strict and almost unreasonable service on the part of a plant has of necessity in some cases driven flowers from the stage, and substituted foliage instead, the latter being more constant and lasting; and the increasing use of foliage instead of flowers in our flower gardens threatens to drive the latter from the field: but a change in public opinion may take place, and flowers be again in the ascendant. Now and then, however, useful additions in the way of coloured foliage have been tried with good effect. The Perilla is grown in many places to a large extent; and not long ago, in a popular flower garden in Yorkshire, I noticed

that Red Beet had been introduced into the flower-beds with tolerably good effect. Purple Orach had been tried many years before, but its use is now on the decline; the more accommodating habit of Perilla fitting it better for the various duties a plant of extraordinary-coloured foliage is called on to fulfil, and in its peculiar tint perhaps no more suitable plant could be had. There are, however, other plants to which it would be desirable to give a trial for out-door work of this kind, and probably with a little coaxing at starting they might do good service.

The AMARANTHUS MELANCHOLICUS RUBER, which I acknowledge to having recommended to the notice of all flower-gardeners last year, has, in a very great many cases, failed this season in giving that satisfaction which it was expected to afford; and at several gardens which I lately had an opportunity of seeing in Lancashire, Yorkshire, and adjoining counties, it was pronounced a complete failure. I confess to having my own misgivings as to its utility in the early part of the season. Since then, however, or rather since the last week in July, it has made rapid progress in the garden here, and at the present time (September 1), it is second to no plant in the garden for general effect; and a plant with a better habit could not well be conceived. I have two rows of it forming lines of colouring in two striped or ribbon-borders, consisting of four rows each, which are respectively Lobelia speciosa, yellow Calceolaria, this Amaranthus, and Cloth of Gold Geranium. The three plants which form its companions are well known, and the Calceolaria and Lobelia are generally regarded as free growers. The Geranium Cloth of Gold is not so free; but the Amaranthus at the present time far outstrips them all. The foliage from the spreading branches having touched the ground on all sides it has been necessary to stop, otherwise it would have spread over the adjoining Calceolarias and Geraniums. The colour, I may observe, is of that rich purple-crimson which contrasts so well with everything around it; and looking at it either in the direction of the sun or the reverse way it is equally beautiful, although it must be observed that there is a difference in the tints it presents when viewed in opposite directions. Its utility is, however, so well established, that I feel disposed to give it a more extended trial next year, but will treat it in a somewhat different manner, having learned from experience that the usual treatment given to ordinary bedding plants is not alike suitable for all.

Taking a view of the treatment which the four varieties of plants forming the ribbon-border above mentioned received, I would observe that the Calceolaria Aurea floribunda was planted out some time about the middle of April. Some in another place were planted out earlier than that and did well; but the Geranium, Lobelia, and Amaranthus were all planted at one time, the second week in May—too soon for the Amaranthus, as the sequel proved: for a great many of the plants dwindled away, forming a sort of abortive seed-stem. The places of those which failed were filled up about the beginning

of June, and up to the end of that month plants were occasionally put in, but it was not until the middle of July that any show was made, the *Calceolaria* and *Lobelia* having done good service in the flowering way for some time. It was now the time for the *Amaranthus* to show its good qualities, for the dry warm weather which set in with July was just the weather that suited it, and just what the *Calceolaria* and *Lobelia* did not like. The *Calceolaria*, after an unusual display of bloom in July and August, is now almost done for; the dry weather not having favoured its growth: a succession of flowers has not been formed, and it is too late to expect them now. The *Lobelia* has done better, and is still gay and likely to be so; the *Geranium* has made little progress; and now, as before stated, the *Amaranthus* requires rather severe amputations to keep it in its due proportion of height and width.

Now, taking the merits of this *Amaranthus* in competition with the *Perilla*, I have no hesitation whatever in giving the preference to the latter for early and general work in all but the most favoured places, as the *Perilla* may be planted early in May and succeed well. Even seedling plants taken from the hotbed with scarcely any hardening-off, and planted out of doors, have done tolerably well, but, of course, better when they were hardened-off a little. The *Amaranthus* most certainly will never endure this. But it has its merits: when it does grow and prosper it far excels the *Perilla* in appearance; the rich hue it presents contrasting strongly with the bronze tone of the *Perilla*, while the habit of the plant is equally good—indeed better in many respects, being more disposed to spread than the *Perilla*, and as an individual plant much its superior. That it may be so treated as to become a more useful member of the flower-gardening family I have no doubt; but I fear it requires a greater amount of warmth or sunshine than it can receive in the north of England, excepting in unusually fine summers. It is, however, well worth trying; and the experience of the present year points out that it is not prudent, even in favoured places, to plant it out before June, and by so doing it is likely it may be made a useful adjunct to the flower garden.

COLEUS VERSCHAFFELTI.—While speaking of the *Amaranthus* it is but right to mention this plant also, which was announced as likely to answer as a bedding plant. In my case, I am sorry to say it has fallen short of what the *Amaranthus* has become, but I did not plant so much of it. A bed in a geometric garden was, however, planted with this *Coleus*, and as it was well sheltered from the north and east I expected it would have done well; but the plants, which were, like most others, all planted before the middle of May, made little or no progress until the middle of August; and since then they have grown a little, but the colour is not that rich hue which the plant has while in the hothouse. I will, however, speak of this plant later in the season, or perhaps some one else will do so. My experience of it goes to prove that it is less promising than the *Amaranthus*, but I believe this is not the universal opinion. Certainly the only plants of it that I have seen doing well had not been long out of the hothouse, so that they could not be said to have grown out of doors. In hot dry summers like 1858 and 1859 I have no doubt that it will succeed; but summers suitable for growing stove plants out of doors are not of yearly occurrence, so we must wait for one to try those delicate ornaments outside with something like a prospect of success. It is many years since I tried *Torenia asiatica* as a bedding plant with *Pentas carnea* and some others with a fair share of success in a hot year, but I met with a complete failure in a dull damp one. Since then I believe *Begonias* have been tried with like success. That it is desirable to make such experiments cannot be denied, but it is better to hold fast to such tried friends as never deceive us for doing service in important places, and to let those on probation have a berth to themselves which will afford them every advantage for doing well; and if they do so let their culture be extended another year, taking care, however, not to be deceived by the well-doing of a plant in a season well adapted for it, so as to be led to expect that it will do equally well in one of a contrary description.

Having extended the above remarks to a greater length than I intended, I must defer until another opportunity the somewhat ungracious task of "weeding" the flower garden

of its useless or superfluous occupants. I would also be glad to have the opinion of others on this head, and would suggest that each writer should class his favourites under different heads—as Class 1, which might include only the very best; Class 2, a secondary section; and Class 3, those which might be used occasionally; but any other arrangement that would convey the idea intended to be expressed would do. The introduction of a new plant is not more serviceable to the gardening community than the removal of existing useless ones, and a good and fearless weeding-out will be of much service.—J. ROBSON.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—SEPTEMBER 9TH.

ON this occasion the Exhibition was held in the deserted saloons of the French refreshment department of the Exhibition building, and the attendance of visitors was such as to render the propriety of holding exhibitions in September very questionable indeed. Those who have country seats have now retired to them; those who are sportsmen are thinking of sport; the larger class of tradesmen with their families are either off for their holiday to the seaside, to the north, or to the continent, or have just returned and have no time to spare; and there only remain those who are chained to the wheel of business, and who, therefore, are amongst the least likely to come in force to flower shows. So numerous, too, have these been this summer, occurring week after week, and too often presenting the same general features, that the public have tired of them, and would now gladly rest for a season. Rain in the morning, continued in some parts round London till noon, combined with a lowering sky, warning drops of rain, and every indication of an approaching thunder-storm, no doubt served, in addition to the above causes, to deter many from visiting the Exhibition; but fortunately, however, during the time this lasted the weather remained fair, though not fine, and it was not till ten o'clock at night that a sharp thunderstorm came on, accompanied by such a downpouring of rain as would have ruined the hopes of many an exhibitor had it occurred on the previous day.

The productions which were exhibited were arranged in four divisions, no one of which could be seen from the other—an arrangement which from the internal nature of the building was inevitable, but which had the effect of spoiling the Exhibition as a whole. It presented no long vista, as at the Crystal Palace, of flowers and fruit—no long array of earnest gazers—and, consequently, being taken in detail, no grand impression could be produced. The rapid demolition going on in the Exhibition building, and visible in all its nakedness through several glass doors, was also little in harmony with what should have been a scene of beauty, although it seemed to be viewed by the visitors with a feeling of complacency rather than otherwise.

We now come to the particulars of the Show itself, which, with the exception of some things in the Miscellaneous Class and those submitted to the Floral Committee, consisted principally of Dahlias, Hollyhocks, Asters, and Gladioli, all of which, and particularly the first and last, were shown in great perfection.

DAHLIAS were even finer than they were at the Crystal Palace, and Mr. Turner and Mr. Keynes again took off the principal prizes in the Nurserymen's Classes.

In 48's no stand could have been finer than that of Mr. Turner; his blooms appeared at the Crystal Palace as if they could not have been surpassed, but on this occasion they were still larger, still more perfect. It would have been impossible to have picked out an inferior bloom among the whole, and it would be tedious to merely give the list of their names, but the following are some of the most striking—viz., Norfolk Hero, Warrior, Sidney Herbert, Mr. Stocken, Criterion, Goldfinder, Pre-eminent, Mrs. Henshaw, Lord Palmerston, Chairman, Bob Ridley, Charlotte Dorling, Earl of Shaftesbury, Beauty of Hilberton, Princess of Prussia (a beautiful canary yellow), Lord Derby, Juno, and Hugh Miller. In the second-prize stand from Mr. Keynes, the blooms were not generally so large, nor were some of them so perfect as Mr. Turner's. Criterion, Lord Derby, Regularity, Fanny Purchase (a fine yellow), Sir J. Douglas, and

Bob Ridley, were some of the most remarkable. Mr. Cattell, of Westerham, was third with an excellent stand, in which we noticed Criterion, Lord Derby, George Elliott, Cygnet, and Charlotte Dorling.

In 24's Mr. Turner was also first with Criterion, George Elliott, Umpire, Mauve Queen, Midnight, Bob Ridley, Juno, Goldfinder, Lord Palmerston, Norfolk Hero, Mr. Stocken, Lord Derby, Andrew Dodds, Delicata, and others. Mr. Keynes was second—Baron Taunton, Anna Keynes, King of Sweden, Leopard, Fanny Purchase, and John Wyatt, being some of the best; and Mr. Perkins, of Northampton, was third, his blooms being also good. Mr. Legge, of Edmonton, Mr. Cattell, and Messrs. Garraway, of Durdham Down, were also competitors.

In the Amateurs' Class of eighteen, Mr. Thornycroft, of Floore, near Weedon, was first, with some very fine blooms of Norfolk Hero, John Dory, Cygnet, Mrs. Piggott, Hugh Miller, Juno, Lord Derby, Mrs. Henshaw, Volunteer, Mr. Critchett, Andrew Dodds, Admiral Dundas, Baron Taunton, Lilac Queen, Model, Lady Popham, Lord Palmerston, and British Triumph. T. Charlton, Esq., of Kebleworth, was second with a capital stand, in which there were many of the kinds already named. Mr. Corp, of Milford, was third; and the Rev. Mr. Fellowes, of Shottesham Rectory, was fourth with a stand in which a yellow seedling, Mauve Queen, Lord Dundreary, and Hugh Miller, were noticeable. Mr. Hopkins, of Brentford; Mr. Sladden, of Ash; Mr. Perry, of Castle Bromwich, and several others also competed creditably.

In eighteen Fancies (Nurserymen), Mr. Keynes was first, with Baron Alderson, Garibaldi, Patent, Triomphe de Roubaix, Polly Fawcett, Carnation, Pauline, Mrs. Crisp, Reliance, Lady Paxton, Oliver Twist, Mrs. Wickham, Nora Creina, Regularity, Leopard, Harlequin, Queen Mab, and Sam Bartlett. In the stand of Mr. Turner, who was second, were fine blooms of The Flirt, Zebra, Summertime, Stafford's Gem (a very pretty crimson tipped with gold), Garibaldi, Harlequin, and Lady Paxton. Mr. Legge was third; Messrs. Cattell, Garraway, and Perkins also competing.

In the Amateurs' Class of twelve, the Rev. C. Fellowes was first with excellent blooms of Pauline, Lady Paxton, Fancy Queen, Oliver Twist, Harlequin, Queen Mab, Flirt, Summertime, and some seedlings. Mr. Corp was second, Mr. Slade third, and Mr. Perry fourth.

HOLLYHOCKS were not remarkable. Mr. W. Chater received first prize; Acme, Warrior, Princess of Wales, Invincible, George Young, and Rev. Joshua Dix were the best. Messrs. Minchin & Sons, of Hook Norton, were second; Messrs. Paul & Son third.

ASTERS.—Both German quilled, and French varieties were first-rate, Mr. Betteridge taking off the first prizes in both classes. Mr. Wyatt, of Epsom, was second, and Mr. C. Sandford third in each class.

GLADIOLUS.—With this flower a grand display was made by Messrs. Youell and Mr. Standish, of Ascot, who were respectively first and second; but it must have been a difficult matter for the Judges to have decided on their respective merits. Owing to the late heavy rains, however, many of the flowers had suffered somewhat, more especially those shown in the Amateurs' Class. Of Messrs. Youell's collection Madame Vilmorin, Ophir, Princesse Clothilde, Napoleon III., Madame Rabourdin, Mazeppa, and Pliné were fine. Mr. Standish had Etna (a fine red), Impératrice Eugénie, Mrs. Dix, George Stephenson, Brian Boru, Charles Davis (a beautiful scarlet with white markings in the throat), and others of which an account will be found in the report of the Floral Committee. There were also extensive collections from both the above exhibitors, which, though not for competition, were very interesting. Mr. Prince, of Oxford, had third prize. La Quintinye, Reine Victoria, Ambroise Verschaffelt, Le Poussin, Rembrandt, Madame Basseville, and Fanny Rouget were those shown best. Mr. Cattell had also good spikes. Among Amateurs Mr. Sladden, Mr. Perry, and the Rev. H. Dombrain were the successful competitors, ranking in the prize list in the order in which they are named. In their stands were good spikes of Prospero, Calypso, Le Poussin, Sappho, Jeanne d'Arc, Victor Verdier (small, but fine in colour), Endymion, and Bridesmaid.

MISCELLANEOUS.—Verbenas were shown in excellent condition by Messrs. Perkins & Son, and Mr. Perry, of Castle Bromwich, who received first and second prizes; fine large

trusses of Phloxes by Mr. Turner, of Slough; several boxes of Roses in good condition by Messrs. Paul & Son, and some excellent Asters in pots by Messrs. Cutbush. From Messrs. Veitch came the beautiful sweet-scented *Lilium auratum*, the curious scarlet *Anthurium Scherzerianum*, the fine crimson-foliaged *Dracæna ferrea variegata*, *Odontoglossum grande*, the large white-flowered *Pancratium zeylanicum*, and other plants, which were submitted to the Floral Committee. Mr. Bull had likewise an extensive group of new and rare plants, among which were *Gesnera Radiancy*, with highly ornamental foliage, some new arborescent *Begonias*, *Adiantum radiatum*, and the beautiful *Marattia elegans*, *Drosera dichotoma*, and several new *Caladiums*. Messrs. A. Henderson had the Cotton-plant in pod; Mr. Salter, variegated plants for ribbon-borders; and Messrs. E. G. Henderson, a selection of Ivies and variegated *Geraniums*; whilst Messrs. Carter & Co. had excellent double *Zinnias*, French Marigolds, Asters, and Everlastings.

The following remarks on the Gladioli and Roses exhibited, are from our valued contributor, "D., Deal:"—

[Notwithstanding the prevalence of disease amongst Gladioli, the stands exhibited were of surpassing excellence, and it was evident that it could not have affected those growers whose magnificent spikes of bloom and luxuriant foliage displayed the very perfection of vigour and growth. The positions of the two great combatants in the Nurserymen's Class were the reverse of that at the Crystal Palace Show, Messrs. Youell being first, and Mr. Standish second. The spikes of bloom exhibited by the former were longer and fuller; but in variety and quality Mr. Standish's were unquestionably the best. He had besides several boxes of blooms, which made a grand display. Amongst the most conspicuous of his flowers were—Ganymede, a fine flower in the style of Poussin; Mrs. Dix, white, of good substance; Lord Clyde, a large and very fine flower; Etna, glowing red; Charles Davis, beautiful crimson with white feathers; George Stephenson, claret, a novel shade of colour; Princess Alexandra, a very novel flower, creamy buff, crimson feather, almost of the colour of a *Dendrobium*; Randle Jackson, light pink splashed with carmine, deep crimson feather; Boadicea, dark crimson splashed with deeper crimson; Brian Born, very large, crimson, violet feather; Edith Dombrain, soft salmon, splashed with deeper shade; Demosthenes, fine shape; Euterpe, white, with violet feathers; Roscius, red, with violet lip; Pollux, cream, with dark red blotch; Mr. Marnock, cherry red; Aurelian, very bright crimson; Margaret, fine white; La Belle, beautiful soft pink; Mrs. Peach, peach, with deep crimson markings; and Mrs. Dombrain, a beautiful flower, something like *Impératrice Eugénie*, but better. In Messrs. Youell's were some fine blooms of Achille, Madame Vilmorin, Ophir, Oracle, Napoleon III., Poussin, Linné, Marie, Pliné, Ophir, and other well-known French kinds admirably bloomed. The same may be said of Mr. Prince's flowers, and of Mr. Cattell's, who had some promising seedlings.

In the Amateurs' Class, Mr. Sladden, of Ash-next-Sandwich, was first with seedlings Cleopatra, Hector, Volunteer, Prospero, Philip Van Artevelde, Sappho, Lord Clyde, Poussin, Adonis, Fanny Rouget, Madame Breol, Courant fulgens. His stand was very effective and excellently bloomed. Mr. Perry, of Castle Bromwich, was second with Jeanne d'Arc, Sulphureus, Calypso, Le Poussin, Madame de Vetry, Mazeppa, Raphael, Marie, Achille, Janire, and Premier de Montrouge. The Rev. H. H. Dombrain was third with Standish's Mrs. R. Hole, Earl of Carlisle, Mrs. Dombrain (fine), Viola, Lucifer, Mrs. Livingstone, and Lemonade; seedlings Lord Warden, Orange Boven, and Bridesmaid, and Victor Verdier and Endymion.

Roses were exhibited in goodly number by Mr. Turner, Messrs. Paul & Son, and Mr. Clarke, of Brixton; they were good for the season of the year, and the prizes were awarded as named. Sénateur Vaisse, Madame Falcot, Maréchal Vaillant, Catherine Guillot, Victor Verdier, Céline Forestier, Triomphe d'Angers, Souvenir de Leveson Gower, Madame Furtado, Comtesse de Chabillant, and other well-known kinds were on most of the stands; but it was surely quite a mistake not to offer prizes at this season for them.]

FRUIT.

The effect of this portion of the Show was much better

than that produced by the floral department, and there was an aspect of order about it, combined with variety, which was very pleasing. Still, as an Exhibition of fruit, it was far from complete, and no exhibition can be considered so where such important articles of the dessert as Pines, Grapes, and Melons are excluded from competition. There is certainly less merit in producing these fine now than at an earlier period of the season; still we think it was a mistake to entirely exclude the above fruits from competition, and to restrict the prizes to out-door fruit only, and that at a time when Apples and Pears are for the most part unripe. Grapes in particular, had they been invited, would have afforded a useful field of observation as regards their comparative earliness and lateness. It would have been desirable, for instance, to have seen whether we could not have really ripe Muscat Grapes in September; for, with the exception of those shown by Mr. Drummond at the Crystal Palace, none have been seen this year at the metropolitan shows exhibiting that beautiful russeted amber colour which is indicative of perfect ripeness. The ripening, too, of the Grapes in the conservatory at Chiswick would also have afforded an excellent opportunity of comparing different varieties, with which view prizes might have been offered for collections of these.

The collections of eight dishes, notwithstanding that good fruit was shown, looked meagre when confined to out-door productions only, and none of them could be considered as furnishing a good dessert. Mr. Turner had first prize for Peaches, Nectarines, Williams' Bon Chrétien Pears, Morello Cherries, Washington Plums, Brown Turkey Figs, and Red Currants. Mr. Henderson, of Trentham, was second, with Téton de Venus and Barrington Peaches, Pitmaston Orange, and Elruge Nectarines, Moorpark Apricots, Brown Turkey Figs, Morello Cherries, and Reine Claude de Bavay Plums. Mr. Kaile was third; and collections also came from Mr. Bousie, gardener to Lord Taunton, Mr. Brush, and Mr. Sandford.

PEACHES.—There were Classes for four dishes, and for single ones, forty-five dishes in all being shown. *Grosse Mignonne*, *Violette Hâtive*, *Barrington*, *Bellegarde*, and *Walburton Admirable*, were the chief kinds. In four dishes, Mr. Dawson, gardener to Earl Cowper, was first with *Violette Hâtive* and *Barrington* (large and fine), *Champion*, and *Téton de Venus*; and Mr. A. Henderson was second with *Bellegarde*, *Madeleine de Courson*, *Barrington*, and *Late Admirable*. In single dishes, equal first prizes were awarded to Mr. Rust and Mr. Kaile; to the one for *Walburton Admirable*, to the other for immense fruit of what was stated to be *Barrington*, but more like the *Shanghai*. Mr. Dawson was second with good well-coloured fruit of *Violette Hâtive*; and Mr. S. Snow third with *Bellegarde*.

NECTARINES, for the most part, consisted of *Violette Hâtive*, *Elruge*, and *Pitmaston Orange*, and were very ordinary in appearance. Mr. Dawson was first in four dishes with *Pitmaston Orange*, *Violette Hâtive*, *Elruge*, and *Balgowan*; Mr. Henderson second. In single dishes G. Wilson, Esq., Weybridge, had the first prize for the *Stanwick* grown in pots in an orchard-house; and third prizes were awarded to Mr. Bailey, of Shardeloes, for *Elruge*, and to Mr. Snow for *Violette Hâtive*.

FIGS.—Only twelve dishes were shown. *Brown Turkey* being almost the only kind. In three dishes Mr. Bousie had first prize for *Brown Turkey*, *Brunswick*, and *White Genoa*; and in single dishes Mr. Bailey had *Brown Turkey* (excellent), and Mr. Sayers and Mr. Snow were second and third with the same kind.

CHERRIES.—Only fifteen dishes were shown, and, with the exception of *Kentish* from Mr. Earley, and *Florence*, they were all *Morellos* and generally very fine. Mr. Snow was first; Mr. Turner second; Mr. Budd, gardener to Lord Darnley, third.

PLUMS were both numerous and good. Some very fine *Jefferson* and *Washington* were shown, also *Victoria*, *Goliath*, *Coe's Golden Drop*, *Green Gage*, *Kirke's*, *White Magnum Bonum*, *Diamond*, and some others. In four dishes Mr. Snow was first, Mr. Cox, Redleaf, second, and Mr. Bailey third; and from Mr. Wilson came some excellent fruit from an orchard-house. Mr. Sayer had *Pond's Seedling*, fine; Mr. Budd, *Jefferson* and *Washington*, very good. Extra prizes were awarded to both of the last-named exhibitors. In

single dishes Mr. Snow was first with *Jefferson*, large and finely ripened; Mr. Knight, *Twickenham*, second with *Coe's Golden Drop*; and Mr. Alves, *Bromley*, third with *White Magnum Bonum*, very large.

APPLES.—More than a hundred dishes were brought forward. Nearly all were unripe, and therefore could not be said fairly to represent the varieties to which they belonged. There were some well-coloured examples of *Fearn's* and *Cox's Orange Pippins*, *Kerry Pippin*, and *Red Quarrenden*. We noticed that some of the exhibitors had evidently been polishing up their Apples with the hand or otherwise, the effect of which proceeding was to remove the bloom; and we would recommend to their consideration how their *Black Hamburg Grapes* would look if subjected to the same process.

In dessert kinds the first prize was awarded to Mr. Bousie for *Fearn's*, *Cox's Orange* and *Ribston Pippins*, all of which were very good; the second to Mr. Mortimore, who had *Cox's Orange*, *Old Nonpareil*, and *Ribston Pippin*. Mr. Wren, of Wallington, was third with *Kerry* and *Ribston Pippins* and *Nonsuch*. Mr. Grover, of Hammersmith, had *Kirke's* incomparable beautifully coloured.

Of kitchen Apples large fruit of *Reinette du Canada*, *Alfriston*, *Hollandbury*, *Alexander*, *Dutch Codlin*, *Dumelow's Seedling*, *Hawthornden*, *Yorkshire Greening*, and some others were brought for competition. Mr. Snow was first with *Alfriston* (very large), *Golden Noble*, and *Cumberlean*; Mr. Anstiss, *Chiswick*, second with *Blenheim Pippin*, *Hollandbury*, and *Lord Nelson*; Mr. Lane, *St. Mary's Cray*, was third with *Alfriston*, *Blenheim*, and *Chancellor* (a large showy yellow and red kind). *Grenadier* and *Cox's Orange Pippin* from Mr. Bousie; *Lord Derby*, *Lord Suffield*, and *Royal Russet* from other exhibitors, were also large.

PEARS.—Williams' *Bon Chrétien*, *Louise Bonne*, *Gansel's Bergamot*, *Chaumontel*, and *Beurré Bosc* were the principal. A first prize was taken by G. Wilson, Esq., with fruit grown in pots in an orchard-house, and which were certainly large and very fine. The varieties were *Louise Bonne* (the best in the Show), *Beurré d'Anjou*, and *Conseiller de la Cour*. First prize was also awarded to Mr. Wren for *Marie Louise*, *Crasanne*, and *Chaumontel*, also remarkably fine. Mr. Beasley, *Twyford Abbey*, was second with *Belle et Bonne*, Williams' *Bon Chrétien*, and *Beurré Diel*. Some very good fruit of *Gansel's Bergamot* and *Marie Louise* were also shown.

MISCELLANEOUS.—A collection of about forty kinds of Grapes from the Society's Chiswick gardens attracted great interest. It contained most of the varieties exhibited in a similar collection at the great October Show last year. There were some fine bunches of *Muscat of Alexandria*; *Golden Hamburg*, very fine; *Frankenthal*; *Dutch Hamburg*; *Raisin de Calabre*, which by-the-by, though not first-rate, is excellent for late keeping; *Albee*, very beautiful; *De Candolle*, and *Chasselas Rose de Falloux*, also very pretty kinds; *Barbarossa*; and many others which may be seen growing at Chiswick, where the conservatory hanging with bunches of all kinds and colours is a sight well worth going to see. Messrs. Lane & Son had some Vines in pots bearing splendid bunches for that mode of culture, also good Pears, Cherries, and other fruit in pots. Mr. Henderson had a fine box of *Moorpark Apricots*, for which he received a first prize; and Mr. Terry, the Hyde, St. Albans, had second for six kinds of Currants, of which *Ruby Castle* were very fine. Mr. Hall, gardener to Lord Scarborough, sent a *Queen Pine* of 5½ lbs., but over-ripe. Some good Melons, consisting of *Golden Perfection*, *Egyptian Green-fleshed*, *Beechwood*, and *Scarlet Gem* were also shown. *Melon Apple*, an American kind, from G. Wilson, Esq., was of large size and had been grown in a pot; and some very fine *Ridge Cucumbers* came from Mr. Leslie.

FLOWERING OF THE AMERICAN ALOE.—I have just read an article from the *Oxford Journal* about the *American Aloe*. I thought long since that English gardeners had given up the idea of the *Aloe* only blooming once in a hundred years. I saw the *Aloe* in bloom at New Orleans in the garden attached to the Mint, and ten years before that it had bloomed. I also was in Mexico for two years, from 1845 to 1847, and had the opportunity of seeing many young plants

bloom; by the appearance of the plants I should say they were not more than from four to five years old. I have no doubt but it is quite a century-plant if grown in the way gardeners are used to grow it in England. The Mexicans take from the Aloe a juice, which, when put through a process, makes a strong drink, so strong that an Englishman would not like a second dose. The natives drink it to intoxication.—E. B. PRINCE, *Darlington*.

CHEMISTRY OF SOILS IN RELATION TO GRAPE VINES—SHANKING.

I AM very much interested in the statement made by Mr. Robson in his account of the graperies of Mr. Meredith (*vide p. 166*), where we find it stated that Mr. Meredith's knowledge will enable him to pronounce whether a certain soil will suit the Grape Vine apart from all those outward appearances which are the only guide to a less practised hand. Until I read this statement it had been my impression that, notwithstanding the present advanced state of chemical science, it was not in the power of any man by a chemical knowledge of soils, combined with a practical knowledge of horticulture, through analysis to determine the due proportion of ingredients requisite to furnish proper aliment, both in quantity and quality, to the roots of any plant—in other words, to be able to take a handful of soil and by analysis to say there is so much of one component in excess or so much of another deficient. Yet it has been my idea ever since I have been able to think for myself that the horticulturist must be continually at fault until chemical knowledge can be thus applied. It is beyond the power of any one by mere inspection to determine without risk of mistake the adaptation or otherwise of a given soil for a given plant: hence the failures which so frequently result from following rules which are in fact incomplete, although they have been proved by a practical man, in his experience, to be sound and good.

My meaning may be made clear by example: A recommends for the culture of a particular fruit a particular kind of loam, say turfy, having been six months cut from a pasture, moderately sandy, and also moderately rich. Well, any gardener has a pretty clear idea of the meaning of these terms, and if a dozen intelligent horticulturists were required to furnish a wheelbarrow-load each for comparison by ordinary inspection, the samples would not be found to differ very materially. Now, if the bulk from which these samples were taken was used in a like proportion, all other points at the same time being equal—say in the composition for a Vine-border—we should expect to see like results; but I affirm that although by mere chance the results may be nearly alike, the probability is that they would vary very much in the different cases.

I should like to have a word upon that perplexing matter, the shanking of Grapes, not by way of attempting to elucidate the mystery which so many cleverer heads than mine have failed to clear up, but rather to elicit opinion, for the more I have studied and observed hitherto the more inexplicable has the matter become. I will, therefore, if you will allow me, for the sake of calling forth opinion and advice, state some of the observations I have made.

In the place where I served my apprenticeship we had a viney filled entirely with Hamburgs. Throughout the whole of this house during my first three years, and likewise for some years before I saw them, they shanked more or less every season. It became desirable to divide this house into two compartments, one of which was subsequently started about January 1st in order to cut from it about the first week in June. The other division was made to ripen its fruit about two or three months later. Now, for the four or five years over which my observations extended, after the division was made, there never appeared, so far as my remembrance serves me, a shanked berry in the earlier forced end, whilst in the later division three-fourths of the bunches were spoilt, as to form and size, through the berries shanking. I must state here that the conditions under which the Vines grew were in no way altered at the time of the division of the house, only that one end was forced and the other not at all, or but very little. The whole of the border was covered with about 9 inches of stable-dung

during winter, as there were no means of bottom heat provided.

In two succeeding situations it fell to my lot to have the care of several vineries both early and late, the borders of some of them underlaid with hot-water pipes, others having none; but in neither of these places do I remember at any time the berries shanking so as to injure the appearance of a bunch of Grapes.

At the place where I am at present I found, five years ago, a late house filled with comparatively young Vines, and here again the Grapes had the old complaint, but not so as to materially injure the crop. Each year since the mischief increased, until in 1862 we had not a good bunch of Grapes in the house, after which I succeeded in persuading my employer to allow me to lift the Vines and make the border entirely anew. This we did in December, when I found the border very compact, being composed of a rich loam which had apparently received a large admixture of rotten dung, there being no grit or rubble in the mass. Large roots were in abundance, but the formation of fibres seemed gradually to have ceased, for scarcely one such calculated to feed a plant could be found.

I, of course, thought the cause of complaint evident enough, and the remedy, therefore, easy and sure; so, after having gathered all the information I could from writers on the Grape Vine, I decided to follow Mr. Thomson's directions, only not using any stable manure in the compost. Good turfy loam from a pasture had been provided, mortar rubbish, half-inch bone, and charcoal in the prescribed proportions being well internixed with it. The Vines were planted in mild damp weather, their roots being spread regularly over the border and covered to the depth of 6 inches. The border was made 2½ feet deep and covered at once with long stable-dung to protect it from the weather. Furthermore, the drainage and aspect are thoroughly good. The Vines broke in March, strongly but rather more slowly than usual; but after a while they, of course, showed the effects of removal. They renewed their growth healthily but not vigorously after the sun had warmed the border to the temperature of 58° or 60° at 1 foot deep. This was towards the end of May. Most of them carried a few bunches of Grapes, which I allowed to remain. On their beginning to colour in August shanking took place as bad as before. This I at first thought might be attributed to the natural inability of the Vines to ripen fruit whilst their energies were so taxed for the formation of young wood. On examining the border I find that the young roots have permeated the whole mass at least to the depth of 12 or 15 inches, but that they are all in a state of decay! The temperature of the border has remained throughout the summer about 6° higher at 1 foot deep than the temperature of the earth as registered at Chiswick. The roots have never at any time been allowed to become dry, although they have not received much watering, as I prefer in hot weather covering slightly to prevent evaporation. As this vinery is in two compartments I intend, all being well, to force the one division rather early next season, in order to see if the result will be the same as it was in the case of the first house of Grapes which I ever had to do with. If any of your correspondents can throw light upon this matter they will greatly oblige.—EPSILON.

LIFTING AND PRESERVING GERANIUMS THROUGH THE WINTER.

"AGNES" says—"I am promised by a friend some of this year's plants of variegated Geraniums—Bijou, Alma, Flower of the Day, &c., also, Golden Chain and Christine, but cannot receive them till the season is nearly over. What is the best method for preserving them during the winter? Should roots or heads be pruned-in or left? Should the pots be large or small? I should like them to look well in the greenhouse during spring and winter if I could, and to be bedded-out in the summer. Does Mr. Thomson mean, in No. 123, that the Geraniums are to be left in the eight-inch pots till bedded-out? and what does he allude to when he says they will be managed the same as detailed in the case of the variegated sorts?"

[When you receive the Geraniums let them be stripped of

all the leaves that choke up the centres of the plants, leaving only those which are fresh and healthy-looking about the points of the shoots. If allowed to remain in the bed till the usual time of lifting such plants, the majority of the leaves of the variegated sorts named will have assumed a somewhat sickly appearance, and these, and all that would be likely to droop and decay about the plants, should be removed at once before beginning to pot. It is not advisable to cut or prune back the stems, because they are apt to die back and cause decay at the main stem of the plants. When we want to prune such plants they are allowed to make roots, and show indications of active life first, and this is not generally the case till after the turn of the year. They may then be cut back, if dwarf plants be the object, and they will soon break at the eyes left, and the tops may be made into cuttings, which strike freely in heat in February. They may either be put singly into five and six-inch pots according to the size of the plants, or several plants may be put into larger pots. The roots should not be pruned beyond cutting back any strong, straggling ones. The soil with which to pot them should be of equal parts loam and well decayed leaf-mould, with about a sixth part of sand, all well mixed together and passed through a three-quarter meshed sieve. Drain the pots well, and in potting see that the roots are well distributed amongst the soil, not bundled into the pot and some soil pressed on the top of them as we have often seen. The soil should be pressed firmly about the roots. When potted give the plants a watering through a fine rose sufficient to wet the whole soil, and place them in a light airy part of your greenhouse. The system of crowding them together in any close frame or house, and keeping them close and shaded, should be avoided as much as possible; it is attended with damping and decaying, and is entirely opposed to the nature and constitution of Geraniums. Through the winter they should just have water enough to keep them from shrivelling, and very little indeed will be sufficient for this. It is a good plan to cover the surface of the pot with dry material, such as charred refuse or very dry fine mould, immediately they are watered at potting time. This prevents evaporation and the necessity for frequent watering, which is undesirable. All damp leaves and shoots should be removed, as soon as they appear, throughout the winter.

If you can introduce them into a gentle heat about the middle of February, they will soon grow and make nice bushy plants that will look well in the greenhouse for a while before planting-out time. But unless potted early, and put into a house with fire heat for a while in autumn, you must not expect them to look very well in your greenhouse in winter, the variegated sorts in particular. But Christine being a very hardy Geranium will sooner recover the shock, and by careful lifting and a slight degree of fire heat after being potted will soon look fresh and nice.

The Geranium cuttings are not left in eight-inch pots till bedded-out, but are potted singly in three and four-inch pots, according to the size of the young plants. This is done in February, and when a little heat can be afforded them after potting, they will the sooner make fine plants, but they are left no longer in heat than just to give them a start. It was simply the "autumn propagation" and winter management that were treated of in the article you refer to, and after they are rooted the common Scarlets are treated the same as the variegated sorts. They are all potted-off into single pots in spring, although I have frequently planted them from the pots they were rooted in; but this course has never been followed except from necessity, either for want of room or pots—disadvantages which I am not called to cope with now. Geraniums will do very well shaken out of the cutting-pots and planted in the beds in the end of May, but they never bloom so freely as nice rustling plants that have been a month or two in single pots, and not crowded together; and shaken-out plants are much later in making a display of bloom.—D. T.]

MUSHROOMS.—I do not think any one need despair of ultimately obtaining Mushrooms because his bed does not bear in the customary six or eight weeks; for I made up two beds in frames last January, and they never produced a Mushroom. I then grew Cucumbers in loam and cocoa-

nut refuse on the beds, and last week the beds, to my astonishment, began to produce Mushrooms among the Cucumbers.—LEX.

THE GLADIOLUS AND ITS DISEASE.

I know of a certain Horticultural Society, whose members, not contented with dry formal committee meetings, used to have occasionally a more social gathering; and it is said that whenever there was a flagging in the conversation some one would begin to talk about this flower, and immediately controversy sharp and strong would spring up as to the proper quantity of its syllables. I do not believe to this day that it is settled—indeed I know but very lately it was proposed to refer it to Dr. Todd, one of the Fellows of Trinity College. Whether THE JOURNAL OF HORTICULTURE will be more successful with its readers I do not know; but I hope its Editors will forgive me if I call in question their *ex cathedra* dictum on the point, for of the three methods of pronunciation that which they have fathered seems to me the most untenable. Gladiolus is unquestionably a diminutive form of *gladius*, a sword, and as a rule all derivatives are short—*e. g.*, *fides* makes *fidicula*; *nutrix*, *nutricula*; and, more to the point, *filius*, a son, makes *filiculus*. Then, again, one vowel before another is short, so that Gladiolus would be even more correct; but I think all analogy is in favour of the pronunciation being Glidiolus. As to the first syllable, that, too, should be pronounced, I fancy, shortly—glid, not glade; but I do hope the Editors will withdraw their sanction to such a barbarism as Gladiolus.

As to the more serious matter of the disease which has manifested itself in the bulb in various places, I wish I could give positive information or suggest a certain remedy. My own experience on the point is, I am happy to say, "nil;" for my small collection of some two or three hundred bulbs is almost, if not altogether, free from it. The question seems to me much in the same condition as the Potato disease, to which it bears a striking similarity, when everything from electricity down to Smee's Aphid vastator was considered to be the cause of it. Let us look at the data which we have—

1. This is not the first season of its appearance. Some collections suffered largely last year; so that we must not, I think, in seeking for causes lay too much stress on the exceptional character of the present season.

2. It is prevalent on the continent as well as in England, though I do not know whether to the same extent; therefore our climate must not be charged with it, as is too often the case.

3. It seems to be more prevalent on heavy than on light soils. Mr. Standish is free from it in the light peaty soil of Ascot; and so is Mr. Youell, whose soil approaches closely, I believe, to that of Holland. In my own light, friable, but rich soil I have hardly seen a trace of it, while from heavy lands and on the London clay it seems to be very severe.*

4. The plan of leaving the roots in the ground advocated by some, and suggested by your correspondent "R. T. E., Shrewsbury," as a probable remedy, does not seem to answer, as your correspondent "T. H. C., Walsall," says that it was only those left in the ground that exhibited this tendency.

5. Potting the bulbs and then planting them out is no protection against it, as my friend Mr. Andrew Henderson told me that that was the system adopted by his firm this year, and that their beds had totally failed.

Such are a few of the facts which have been brought forward, and although by no means sufficient to form an accurate judgment from, they are enough to make a probable one; but as this flower is now become so much in vogue, and is so great an addition to our autumn flowers, it would be most desirable that those growers of it who are readers of THE JOURNAL OF HORTICULTURE should send in a statement of their own experience, where they obtained their bulbs from, the nature of the soil, situation, mode of treatment, and results. I happened to meet my friend, M. Charles Verdier, at the Crystal Palace Autumn Show the other day (where the paucity of exhibitors in this flower told the tale

* I know this is contrary to "H.'s" experience in the "Florist and Pomologist," page 123; but he gives no instances, and it is not so in the cases I know.

of disease), and had with him some little conversation on the point. His opinion (which rather coincides with my own notions and is opposed to that of Mr. Standish), is that it is the result of the excessive moisture of last summer, and, indeed, I may say of the last two years—at least the autumn of 1861, when bulbs were maturing, was so; and that hence the bulbs were not sufficiently dried-off. I am the more confirmed in this from my own slight experience. My stock consisted of a quantity of my own harvesting, some that my friend Mr. Standish was good enough to send me, a few of the new sorts obtained from MM. Thibaut and Keteleer of Paris, and a few from Messrs. Barr & Sugden, also French roots. In only the two latter, and that in not more than five or six instances, have I had failures; and even they were not in the manner described by your correspondents, but simply the rotting-away of the roots.

My own plan of drying is very rigid, and I know Mr. Standish is equally particular, although, from having an immense stock and larger means of harvesting at his disposal, he adopts more effective plans. But I watch carefully the beds; and as some sorts are earlier than others, I take them up as they ripen-off, and put them into a small flower-pot with their label, and bring them into the house. In the back kitchen there is a copper close to a patent kitchener, where there is considerable heat, and here I place them. They remain for a couple of weeks until they are quite dry, when I put them into paper bags and lay them by. That they will bear some considerable drying-off I have proved, for a small box of mixtures was forgotten for some weeks, and when taken out I did not think they were good for much. I, however, planted them out in an out-of-the-way place under the shade of trees, and there they have grown and bloomed most vigorously. I have not watered this summer—at least one of my beds, and that the most vigorous, has not had a drop, so that I do not think M. Loise's notion is likely to be correct; however, as I have said, we hardly have data enough to go upon as yet.

Those of your correspondents who fancy that the bulb formed will be all right, will be, I fear, mistaken; but at the same time I would not have growers discouraged. It would seem almost hopeless at present to grow them on heavy soils, unless very materially lightened by a good admixture of leaf mould and sand; but I should say that in all light or lightish soils they may be again attempted.

The disease seems in some way to be connected with climatic influences, and results, probably from exceptional causes. These may be removed, and the bulb itself acquire more hardiness. Hollyhock-growers will remember, as I was reminded by Mr. Laing, that some years ago the same thing took place in that plant. Collections were cut up, and the attempt to grow the flowers pronounced hopeless. It, however, after some years of much heart-burning to growers, wore itself out, and the plant is now seldom attacked with it. So with the Gladiolus, I believe. We may hope to see it tide over its present difficulties; and no one, I think, who has seen a collection of them as cut blooms but will desire to see them extensively grown. As ornamental plants for gardens I question if they will ever be very effective, but as cut flowers they have few rivals. They bloom so well in water, daily expanding their flowers, and are so vivid and varied in their colour, that they must be great favourites.

My ideas on their cultivation would be, Dry the roots well, keep them in a cool place to prevent their growing too early, manure highly in the autumn, and again give a slight coating in spring, and do not plant too early.—D., Deal.

STRAY NOTES ON RED BEET.

HAPPENING lately to be in a nobleman's garden in the north of England, in passing along the kitchen garden a plot of Red Beet attracted the attention of my friends, and it was determined by the head gardener, a shrewd, well-informed member of his profession, to examine a root of each of the three kinds grown. One of the varieties presented a rather coarse-looking leaf, much veined with green; another was somewhat like it, but with less top; while the third would have been a great acquisition to the flower garden, its foliage being small and firmly set on, and of the

most beautiful rich crimson that could be wished for, each leaf shining in the sun; and many would have pronounced this at first sight to have the best-coloured root. But on examination it was found not to be so. The best one of the three kinds grown was the one with the large coarse-looking top, thereby affording another illustration of the proverb, that we are not to be led away by outward appearance only, and as this is not the first time I have observed the same thing in Red Beet, I thought it would be well to record it. Red Beet of good quality has always been an article anxiously looked for, and as the best kind is apt to degenerate, new varieties, or rather the maintaining of a good quality in its colour and character is an important affair, as, like most other objects of merit, seed from the very best is much less plentifully produced than from a common sort. Soil and situation have also some influence on its colour, not that a really good variety would come bad on an unsuitable soil, but simply it would be a shade less beautiful than the same on a soil better adapted to it. The dark sandy soils bordering some rivers produce the best Beet that I have seen, while on the other hand the best varieties degenerate in two or three years if confined to a chalky district, and, consequently, require to be renewed by importation of seed from a more favoured locality. Beet, therefore, like everything else, requires renewing; and although it may, under favourable circumstances, have reproduced itself in good condition for a great number of years, such success is chiefly due to the care evinced in removing all defective roots, and each year cultivating it on fresh ground. But the question has yet to be asked, Are not a great number of the roots reared yearly from seed saved on the same spot deficient in some point necessary to entitle them to be regarded good, which might not be the case if a change or cross took place?

It is needless here entering into the details of culture which have been given elsewhere, but I may state that a too rich soil is by no means wanted for Beet, as the amount of watery juice it there imbibes drains away after the root is cooked and sliced, and the root assumes a withered appearance. As my object was more particularly to direct attention to the deceptive character of the foliage as indicative of what the roots are, I must leave to other hands the task of explaining the necessary points in the cultivation of this vegetable.—H. T.

PROPAGATING CLOTH OF GOLD PELARGONIUM.

IN answer to an inquirer signing himself "NORTH BRITON" in No. 126, I am afraid that by the time this is in print it will be too late to do much in propagating the Cloth of Gold Pelargonium from leaves. Succeed he may to a certain extent, but he will perceive presently that the season is too far advanced to carry out the principles on which this mode of propagating is best conducted. But I hope that "NORTH BRITON" and others who may read this will remember that I am only an amateur, and that, while I describe my own process, others may be able to give a far better; and no doubt experienced propagators at nurseries would laugh at a poor parson daring to leave his pulpit to occupy their bench and lecture on propagating Pelargoniums. But as I believe numbers of your readers are, like myself, amateurs, who would be glad to give others the benefit of their own limited experience, or any discoveries they may make; and as I also knew it to be a fact that many first-rate professionals in gardening are unacquainted with a very simple but rapid mode of propagating Pelargoniums, I venture, very humbly, to lay my own little secret before them.

In order to convince you, ladies and gentlemen, that my process is a really good one, I beg to inform you that when Pelargonium Christine first came out a small spring-struck cutting, with only some four or five leaves on it, was given me in a certain month of May, and, believe me, the May following was a very merry one to me whenever I looked at the children, grandchildren, and great-grandchildren of my spring-struck mother Christine; for there they were, eighty of them, as blooming, hearty, and strong as if I had gone to Messrs. Henderson or Kinghorn and paid 2s. per dozen for them, which was about their price that season.

With reference to Pelargoniums, the phrase "Propagating

by leaves" is not suitable. Begonias, Cacti, and several other succulent-leaved plants may be said strictly to propagate by leaves, but not Pelargoniums. Together with the leaf you must have a joint, and at the union of the leaf to the joints there must be a bud visible. Pelargoniums, therefore, may strictly be said to propagate from eyes or from single joints, and yet it is not every joint that will make a plant. For instance: those joints which have a leaf on one side and a flower-stalk on the other, though they may succeed in rooting, will seldom grow into a plant. But take a good strong cutting of your Cloth of Gold Pelargonium—say it is 4 or 5 inches long, with four well-developed leaves growing on opposite sides at each alternate joint, besides two top joints, the lowest with the bud just bursting into leaf, and the topmost with two or three young leaves on it. These two last had better be put aside till you have two or three more of a similar growth to pot with them. Take now your four lower leaf-joints, cut them in the usual way about the eighth of an inch below and rather more above each joint, and you have four leaf-joints with buds in the axil of the stalks, besides the two top ones—six in all. Have a pot ready with plenty of drainage, and filled to within half an inch of the rim with soil made up of light loam and leaf mould, and a good quarter share of silver sand in it. Press the soil firm, and add a little more if after pressing the surface is more than half an inch from the rim. Prepare now four little sticks about 9 inches long, take one and push it firmly into the soil. Close to the stick make a small hole half an inch deep, and in the hole just press one of your joint-cuttings so that the leaf stands at right angles to the rim of the pot; tie the leaf to the stick. Proceed in the same way with the three other joint-cuttings, and you have a pot with four masts and four lug sails set to catch every breeze and ray of sun to convey the cargo below on to the next potting season. Give the pot a shake, and sprinkle over the surface of the soil about the eighth of an inch of silver sand. The two little top joints may be treated in much the same way when you have others of a similar growth sufficient to fill a pot. Your cuttings so prepared will require to be dewed only with a syringe, and shaded from hot sun for three or four days. After that the hotter the sun the better, being careful only to give a syringing three or four times in the course of the day; keep, however, from drenching rain. In three or four weeks the buds will be pushing out tiny leaves; and if you began propagating in July, by September each bud will be a plant from which you may take some half dozen more leaf-cuttings.

There is, however, a mode of preparing the mother plants from which to propagate, by a system of alternate forcing and hardening, which I shall be happy to lay before your readers on a future occasion. The season is now too late for it. It is not too late, however, for leaf-cuttings, and I shall probably be making some hundreds this week; but when they have formed a callus I shall give them a little bottom heat to start them and strengthen them for the winter, in hopes of getting more stuff off them in the spring.

I am sorry that my absence from home prevented me from sending you this before; but "NORTH BRITON" can try his hand, nevertheless, if he begins at once.

What a magnificent season this has been for crossing Pelargoniums! I hear there are lots and lots of fine things coming out next year; but what wonders shall we see the season after! By-the-by, these names "Pelargonium" and "Geranium" are a great nuisance. I know "Pelargonium" is right botanically; but is it not possible to come to some general understanding that "Geranium" means all the bedding classes, while "Pelargonium" means the exhibition varieties, blotched, spotted, and foreign and fancy? Let the heads of the trade meet before their next catalogues are out, and give the public some decided signification to the two words "Pelargonium" and "Geranium."—F. W. ADEY, *The Cell, Dunstable.*

EXTRAORDINARY BROCCOLI.—A specimen of the "Southampton Broccoli," grown in the parish of Mortimer in this county, was recently exhibited for a week in the window of Messrs. Sutton & Sons, of Reading. The weight in cooking order was 17 lbs. 6 ozs., and the measure round 4 feet 6 inches.—J. S. B., *Hurst, Thoyford, Berks.*

WELL HEAD GARDENS, HALIFAX, YORKSHIRE.

(Continued from page 194.)

THE next house is a stove, 62 feet by 18, with a centre bed, under which run several hot-water pipes, and there is a shelf all round on a level with the glass. At one end of the pit a tank containing aquatics is charming. The Sacred Bean (*Nelumbium splendens*), was in flower, and *Nymphaea Devoniana*, *dentata*, and *cerulea* occupied the remainder of the tank. Of plants *Lasiandra Fontainesiana*, 6 feet high by 3; *Ixora coccinea superba*, 4 feet by 3, and *I. javanica*, *alba*, &c.; *Clerodendron fallax* and *C. Thomsoni*, *Centradenia grandifolia* (very fine), and the curious *Aristolochia trilobata*. All the varieties of this genus are grotesque enough for anything, and form fitting companions to *Nepenthes*, or Pitcher-plants. *Aristolochia ornithocephala* is the most singular plant I ever saw. It has the head of a hawk and the beak of a heron, with the wattles of the Spanish fowl, which, however, are grey netted with brown; the head the same colour veined, whilst the beak is grey—the gorgeous flowers of *Echmea fulgens* contrast well with the foliage, thereby fitting it for a good place on the dinner table. *Musa Cavendishii* is well cultivated. Fruit weighing 42 lbs. was lately cut, a notice of which appeared in this Journal, but it was stated to have been weighed with 14 ozs. to the pound instead of 16 ozs. However, there is no such local weight as 14 ozs. to the pound, though there is 16 lbs. to the stone; therefore the weight of the fruit was 42 lbs. avoirdupois. Here are also large specimens of *Allamanda Schottii*, *grandiflora*, and scores of fine-foliated and variegated plants, as *Croton variegatum* and *pictum*, 4 feet by 5, *Dieffenbachia maculata*, *Dracenas*, *Pavetta borbonica*, *Colocasia macro-rhiza variegata*, *Pandanus javanicus foliis variegatis*, 8 feet through, &c.

Descending by a few steps we enter, from the stove, the show-house, 30 feet by 18, now gay with *Petunias*, *Fuchsias*, and *Geraniums*. Here I fell in with that good old free-flowering plant, *Campylia elegans*, a plant of which, 3 feet across, is no despicable object. Plants of the old tuberous *Geraniaceae* are as curious as *Orchids*, but no one seems to care about them. At one end of the house was a fine specimen *Cyathia australis*, whilst the other was ornamented by a magnificent specimen of *Dicksonia antarctica*, *Cattleya Lemoniana* in flower, and in baskets suspended from the roof were *Stanhopea insignis* and *oculata*, both in flower.

Proceeding a couple of yards further on we enter the Orchid-house, 30 feet by 20, heated by hot-water pipes in iron troughs. These troughs, which can be filled with water when moisture is wanted, are about 2 feet wide and 10 inches or 1 foot deep, and at the bottom a couple of four-inch pipes are placed, of course longitudinally. Now, by this system—which, in my humble opinion, is superior to all others—the atmosphere of the house can be made moist, even saturated, without syringing much, or dry as circumstances require. Its other advantages are, the amount of evaporating surface is large, therefore the plants imbibe the moisture at a temperature never exceeding that of the house; and that there is none of the stew-pan tendency of hot-water gutters fixed on hot-water pipes, for the troughs are on the floor under the shelves, so that the heat and moisture must be thoroughly diffused through the house before it reaches the plants. In short, the troughs give the genial and beneficial effects of a tank without any of its drawbacks, as moisture in winter when it is not wanted.

The Orchid-house is divided by a partition of glass, and is a double span. Amongst a choice but not large collection I noticed good plants of *Anacochilus Lobbi*, *Lowi*, *setaceus*, *argenteus pictus*, *striatus*, and *xanthophyllus*, growing in fibry peat, sphagnum, and silver sand. The surface of the pot being covered with the last, the compost is kept moist. A bell-glass encloses the plants, and is tilted a little on one side, for these gems above all other plants detest a stagnant atmosphere, though it must be close, water on the leaves, and a sour soil. Of plants in bloom were *Calanthe masuca*, *vestita rubra* (crimson eye), *vestita aurea* (yellow eye); *Peristeria elata*; *Miltonia candida*, *Clowesiana*, and *spectabilis*; *Oncidium sphacelatum* and *papilio major*, and *Trichopilia suavis*. Out of flower, but not less interesting, were *Phalenopsis Schilleriana* with fine leaves, *P. amabilis*, and

grandiflora; *Vandas insignis*, tricolor, Roxburghi, and *corulea*; *Ærides crispum*, odoratum majus, quinquevulnerum, virens, major, and *Warneri*; *Oncidium Lanceanum*, pulchellum, &c.; *Saccolabium Blumei*, and very many more varieties of these now-popular plants.

In the other division I noticed the shelves or tables were covered with sea gravel about the size of a horse bean, which does not choke the drain-holes of a pot like sand, and it imparts a clean aspect to the whole. Here were two examples of that very odd-looking plant, *Alocasia metallica*, with more than a score of leaves on each, forming, with *Musa vittata*, the best set-off for a dinner table that I can imagine. Put the *Musa* in the centre and relieve it with *Adiantums* around it, and set the *Alocasias* one at each end of the table, and they will cause a sensation. The *Alocasia*, though a slow grower at the best, grows here like a Colts-foot, and sends up suckers like Willows. The *Musa* in question is the noblest-looking plant I have yet seen. It has the habit of *M. Cavendishii*, but with a somewhat longer and narrower leaf, having stripes of silvery whiteness cross-wise on the upper surface of the leaf. The plant here is 6 feet high with six leaves about a yard long. Here, too, is a plant for the curious, the Lattice-plant from the pools of Madagascar, growing in the water of an inverted bell-glass, and *Sarracenia purpurea*, *variolaris*, *rubra*, and *Drummondii*, flourishing in sphagnum, fibry peat, and cocoa dust. How happens it that these hardy plants require a high temperature? Not less interesting for the beauty of their foliage were *Pandanus elegantissimus*, with red-edged leaves, charming for dinner-table decoration; *Campylobotrys refulgens*, with bronzy red-coloured leaves, having a satiny lustre; *Saccharum violaceum* (Violet Sugar-cane), with the habit of a grass, having rosy-violet stems and young spray of the same colour drooping gracefully when mature, and excellent for the dinner table; *Cyperus alternifolius variegatus*, which requires a poor soil, and is sure to come in character if grown in pure sand only—green or variegated, no plant excels this for ornamental purposes—nice plants of *Gomphia theophrasta*, rightly named, as it much resembles a *Theophrasta*; *Eriocnema marmorea*, with a smooth *Gloxinia* leaf beautifully dotted with silver; *Quassia amara* (Bitter Quassia); *Maranta vitata*; *micans*, a pretty-leaved kind with a red midrib, &c.; *Caladium regale* and others, not excepting *C. Lowii*; and *Cissus porphyrophyllus*, just contrary to *C. discolor*, which loses the beauty of its leaves in proportion to their age; but this gains in colour with age; the leaves have more substance, and are round instead of ovate. I may add *Sphærogyne latifolia*; *Hibiscus Cooperi*; *Phyllagathis rotundifolia*; *Cypripedium villosum*, *Lowii*, *Hookeri*, and *hirsutissimum*, and many more new and rare plants too numerous to mention. I must not omit noticing a pan of seedling *Alocasias* just peeping from beneath the soil. There were about a dozen of them, but what they will be when developed is another question. The seeds were a cross between *Alocasia metallica* and *Caladium marmoratum*, the former being the female parent or seed-producer.—G. A.

(To be continued.)

NOTES ON THE BEDDING-OUT AT THE CRYSTAL PALACE, BY AN AMATEUR.

MR. ADEY has already given your readers the benefit of his opinions on the bedding-out at the Crystal Palace, but, perhaps, you will not object to insert a few further notes on the same subject by an amateur.

Like Mr. Adey, I took my first look at the garden from the doorway directly facing the Rose Mount, and the first thought which entered my mind was, "Oh! how different to last year!" accompanied by a feeling of disappointment, which, perhaps, prejudiced me throughout my visit. However, I took out my note-book and proceeded to take down the planting of the festoon-bed round the Rose Mount and the beds inside, and then hurried off to examine the beds round it on the outside. Here my feeling of disappointment was increased; for where I last year spent a long time taking notes, this year I scarcely found a single bed which attracted me or invited inspection.

One bed, which was planted with a light pink *Verbena*

edged with a white *Verbena*, was very tame from the entire absence of contrast or shading. Another, the arrangement of which consisted of alternate circles of *Cerastium* and *Gazania splendens*, seemed to depend for effect more on the contrast of the foliage than anything else, and the blossom of the *Gazania* rather spoilt it than otherwise.

There was a something which offended the eye when this part of the garden was viewed from the Rose Mount, but what it was I did not discover until I had seen the effect of the garden on the terrace from the Palace.

Judging from my experience of last year, I still felt sure that I had a treat in store in the chain-border. But, alas! here again I was doomed to disappointment. That which last year was the most beautiful and effective thing in the way of planting that I have seen, was this year not a chain at all, properly so called. Whatever can have induced the designer of those beds to sever all the links of the chain by connecting them with *Lobelia Paxtoniana*, instead of making the chain continuous as it was last year, by carrying the edging of *Alyssum* all round, and thereby entitling it to be called "chain"? This struck me as being the greatest mistake made in the planting in the whole garden; for not only is the beautiful effect of the continuous chain, over which last year the eye never ceased to wander with delight, completely broken, but two lines, one of white and the other of blue, running at right angles to each other, are by no means calculated to contrast well.

When I had mounted to the Palace and viewed the terrace-beds from that commanding position, I discovered what it was that had offended my eye from the Rose Mount. That which struck me as being the great difference between the planting this year and last, is, that last year the prevailing idea seemed to be *contrast*, whereas this year it appears to be *shading*. In consequence of the plan pursued in carrying out this latter idea, the eye is attracted by large and almost unvarying masses of scarlet shaded with pink, almost unrelieved, and the effect is very wearying to the eye. This it was which struck me in some of the beds near the Rose Mount, and much more strongly in the grand view of the terrace garden from the Palace.

The beds which interested me most, and the effect of which I was most careful to observe, were those in which appeared *Amaranthus melancholicus ruber*, *Coleus Verschaffelti*, *Centaurea candidissima*, and *Centaurea gymnocarpa*, the first and two last of which I do not remember to have seen before.

I was some little time making up my mind which had the best effect from a distance: *Centaurea gymnocarpa* edged with *Coleus Verschaffelti*, or *Amaranthus melancholicus ruber* edged with *Centaurea candidissima*; but I finally decided in favour of the latter, the *Amaranthus* having very much the effect of an extremely handsome blossom. There were other plants in the same beds, but those which were not hidden by the plants I have named by no means contributed to improve the effect. The unpleasant impression left on my mind by the rest of the garden was quite effaced by an inspection of these "coming favourites," though it is said that the *Coleus* is to be abolished as a bedding-out plant.

I cannot conclude without expressing my opinion that there is one great improvement which might be made, and which would be of great assistance to those who, like myself, go to the Crystal Palace to take notes of the bedding-out, in order to assist their friends in making their plans for laying-out their gardens the following year—it is to give the names of the plants used. It cannot be expected that an amateur who spends most of his time in working at a profession can know the names of all the different *Geraniums*, *Calceolarias*, &c., which are used in the bedding-out at the Crystal Palace and other large public gardens, and at the same time it is of little use for him to note down "*Scarlet Geranium*," or "*yellow Calceolaria*," when the former may be "*Crystal Palace Scarlet*," "*Cottage Maid*," or "*one of Mr. Beaton's new Geraniums*," and the latter may be "*Aurea floribunda*," or "*Gaines' Yellow*." Surely it would not cause much extra trouble if small tallies were placed in each bed showing the names of the sorts used. They need not be too conspicuous, and they would be a great convenience, and would add much to the very great interest which all who care to have their gardens

gay and planted according to the fashion must take in the system of bedding-out pursued at the Crystal Palace and other places which professedly set the fashion. A single mistake made in taking down the name of a plant may spoil a whole garden next year.—W. H. B.

ALOCASIA METALLICA.

This ranks among the most distinct and peculiar, as well as the most beautiful of the fine-foliaged plants which have been introduced from Borneo of late years. It strikes the eye at first sight as one of the most curious-looking objects of the vegetable kingdom, and those who have not seen it can scarcely form a correct impression of its polished bronzy appearance. Its leaves have all the solid and lustrous look which belongs to a shield of polished bronze; and their ovate-oblong, peltate shape presents an outline somewhat like a tortoise's back. Their stalks being short and stiff, the outline of the plant is compact and massive. Few subjects are more conspicuous in a collection of ornamental-foliaged plants, and where only a dozen kinds are grown it ought to be one of the number, more particularly as it is evergreen, retaining its leaves in beauty all winter, and is, moreover, a plant very easy of cultivation. Any person who can command a high moist stove temperature can have few difficulties to overcome in the culture of *A. metallica*. These remarks are intended for any readers who have not yet seen this plant, while the following brief directions as to its culture are at the request of a correspondent.

Very turfy peat and loam, broken up with the hand and mixed in equal proportions, with the addition of about a sixth part of the whole of well-rotted leaf mould, and a sprinkling of silver sand and charcoal broken up fine, is a compost that suits this *Alocasia* well. Supposing that you have a healthy young plant well established in a six-inch pot and in need of a shift, it may safely be transferred into a nine-inch pot. The drainage should be carefully secured, and the crocks thinly covered with a layer of the most fibry part of the soil. The operation of shifting need not have anything peculiar about it different from any other free-growing plant. In placing the fresh soil round the ball be careful to preserve the strong fleshy roots, and keep the bulbous-looking base of the plant rather high than otherwise. As already mentioned, it requires a high stove temperature to grow it freely, and a moist atmosphere is indispensable to a healthy development of the foliage. It should be placed near the glass, and carefully shaded from the direct rays of the sun for the greater part of the day from the 1st of April till the middle of October. To grow it with all the compactness and strength which it is capable of acquiring it should have plenty of room, and be kept quite close to the glass. When crowded among other plants, and far from the glass, it becomes drawn, and loses that massive and imposing appearance peculiar to it when well grown. With a high temperature—say 75° at night—and potted in open well-drained soil, it delights in a good supply of water, and under these conditions will in one season form a large handsome plant—an object well worthy of any extra care and trouble which may be bestowed upon it.

I recently had the pleasure of visiting the garden of an amateur who does all his own gardening so far as the care of his plants is concerned: and among the many operations which he performs with more than usual success I was particularly well pleased with the appearance of his Orchids and fine-foliaged plants, and struck the moment I entered the stove with the peculiar sweet and balmy atmosphere of the house. There was a high temperature, and a more than usually pleasant feeling on entering from ainery in which Grapes were ripening. It was not difficult to discover the means from which so desirable an atmosphere and so healthy a growth arose. The amount of hot-water pipes from which the heat was imparted was quite double that usually met with, and they just felt a little more than milkwarm. Over the pipes there was a strong sparred trellis, and on the trellis were placed sheets of lead turned up at the edge, so as to form shallow trays, which were filled with water. Common garden saucers were turned upside down in the water, and on the saucers were the fine-foliaged plants; while most of the Orchids were suspended overhead. The atmo-

sphere thus produced was certainly the most pleasant for a stove that could possibly be conceived, and the plants gave ample testimony as to its healthful influence on vegetation. The water used in the trays was rain water, and could be drawn off at any time when it became necessary or desirable by means of a few taps in the bottom of the shallow trays.

The heat derived from so large a surface of pipes in proportion to the amount of atmosphere to be heated can never have that scorching effect that exists when it is derived from a smaller amount of heating surface violently heated; and the water in the leaden trays over the pipes gave that supply of moisture necessary to the development of healthy growth in such plants in a much more natural way and to a better-proportioned extent than is attainable either by syringings over the foliage or by evaporation from a strongly-heated surface. Besides this it is a well-known fact that with such a supply of piping as was used in this case the consumption of fuel is less. In any case it is a great mistake to so limit the heating surface as to render a violent heat necessary to keep up a given temperature.—D. THOMSON.

BORONIA RUTOSMA (RUE-SCENTED BORONIA).

Nat. ord., Rutaceæ. *Linn.*, Octandria Monogynia.—Glaucous, much-branched; leaves oblong-ovate or obovate, sessile, fleshy, apiculate, one-nerved; flowers in trichotomous, corymbose, many-flowered cymes, pedicels thickened beneath the flowers; calyx-lobes ovate acute; filaments ciliate in the lower half.

This very pretty *Boronia* is known in cultivation as *B. spathulata*, but does not appear to be the species so named by Dr. Lindley, differing obviously in its much-branched habit and its many-flowered corymbose inflorescence. The whole plant has a tendency to trichotomous branching, and thus forms a dense bush, with terete branches scattered with glandular dots, and bearing opposite, fleshy, glaucous, oblong-ovate, or obovate apiculate leaves, furnished with numerous transparent dots, and one-nerved. The flowers terminate the branches, forming a kind of corymbose cyme trichotomously divided; the pedicels are about an inch long, thickened at top; the calyx-lobes are ovate acute, brownish-green, dotted, and traversed by forked nerves. The petals are ovate, apiculate, patent, twice as long as the calyx, pink, becoming deep rose when dry. The eight stamens are as long as the calyx, ciliate in the lower half, covered externally above with round glands, the anthers

attached below the apex. The ovary is seated on a broad hypogynous disk twice its own width, and is dotted, four-lobed, terminated by a simple style, with an obscurely four-lobed stigma. The cells of the ovary are two-ovulate, but only one seed seems to be perfected. The plant, both fresh and dry, has a strong odour of Rue.—(*Garden Companion*.)

MARKING TREES.

EVERY one has felt the want of some effective plan of marking fruit trees in the orchard. All sorts of labels have been tried; and most persons depend for strict accuracy on having a manuscript list made of the trees as they are numerically arranged on the ground. This is very well; but as one must have the list always about, or sometimes likes to graft several kinds on one tree, the plan is so far objectionable.

Now it is a well-known fact that the scratch of a pin on the bark leaves a scar that endures almost with the life of the tree. We were shown a Beech tree recently in Delaware county by a middle-aged man with the initials of his father still plainly traceable, which were scratched on the bark when his father was a boy. The same can be done with fruit trees, as we believe we saw suggested some years ago in an agricultural journal, but which, like a good many good ideas that yearly float over the great sea of the agricultural press, has nearly been forgotten.

We saw some trees a few days ago that had been marked in this way, and it reminded us that the idea was worth resuscitating.

The annexed cut will explain the idea clearly:

The letters of the name are scratched on the under side of the branch, and the letters one above the other. In the case we saw there were two kinds on the two arms of the tree—Baldwin and Northern Spy; the main or central stem being of another kind, the name of which we do not now remember.—(*American Gardener's Monthly*.)

RAPID DECAY OF ZINC TANKS.

ABOUT two years since I built a small greenhouse and propagating-house, which I heated by a tank of zinc covered with galvanised sheet iron, as being stronger to support the plunging material for propagating in than zinc. I found on opening the tank a few days since that a white deposit had formed on the under side of the sheets of galvanised iron, some of which I have scraped off and sent with this, and shall be much obliged if you could ascertain for me the nature of it. This deposit has fallen in places into the zinc tank and corroded it nearly through. The zinc is, in fact, worn into small holes, which are so nearly through that a pin penetrates them as easily as it would through brown paper.

My object in writing is twofold: first to be of use to any persons who may be about to make tanks of zinc in cautioning them not on any account to cover the tank with "galvanised iron;" and next, to ascertain what will be the most effectual and economical means to remedy this disaster. Would you recommend a wood tank or another zinc tank covered with slate? The tank worked so satisfactorily until it began to leak from the cause above stated, that I much prefer this plan of heating to that by pipes. If I put a zinc tank the present framework of wood would do; but if in a wood one, it must be new altogether. I conclude that in the course of the circulation of the water some of this deposit must have gone into the boiler, and I suppose that if I have a new zinc tank it will probably be again discharged to some extent by the same means out of the boiler into the tank, and will, probably, again corrode the new zinc unless its effect has become neutralised by remaining some weeks in the boiler. Of course, I could have the boiler cleaned out, but I do not want to have to do this if possible,

as it will involve considerable trouble and some expense in removing the boiler and replacing it.—A COUNTRY CURATE.

[We cannot spare the time nor incur the expense of chemical analyses. The white deposit is such as will be generated in zinc tanks wherever the water is not very pure, and even then, in time, the metal will be corroded by the carbonic acid in the water and the oxygen in the air. In your case the corrosion would be accelerated by the galvanic action induced by the iron and zinc being in contact. A wooden tank covered with slate would be far more lasting and useful. We have seen galvanised iron used; but whenever an opening in the galvanic covering is made, the iron inside corrodes very quickly. We have had zinc tanks in addition to pipes to give more heat, and, strange to say, the lids corroded much sooner than the sides or the bottom. For cheapness and lastingness combined, we would recommend a wooden tank. If you still resort to zinc, you had better have a zinc covering likewise. In your case there would be several chemical combinations.]

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—SEPT. 9, 1863.

FLORAL COMMITTEE.—The autumnal Exhibition of the Royal Horticultural Society was held on this day, and, as far as flowers and fruit were concerned, nothing more could be desired. The Floral Committee had much to occupy their attention. The entries for seedling Dahlias alone were very numerous, besides a long table well covered with other specimens for inspection. Not more than one-fifth of the seedling Dahlias exhibited received any notice beyond general approval; and out of the twenty certificates awarded this day, four only were first-class. The Committee have not awarded more than six first-class certificates to Dahlias of 1863. This most conclusively proves that this favourite florists' flower has arrived at its climax, and the innumerable good sorts now in cultivation cannot easily be surpassed by new ones. Our report must necessarily be a lengthy one; we shall therefore omit the description of the seedlings which received awards. They will doubtless be criticised by other writers in the Journal.

Dahlias—Mr. Wheeler, Warminster: Coronet, first-class; Watty, second-class; Symmetry, commended at the previous meeting. Mr. Kimberley: Messenger, second-class. Mr. Rawlings: Tom Thumb dwarf bedding variety, commended. Mr. Bragg, Slough: Useful, second-class; Garibaldi, second-class. Mr. Keynes, Salisbury: Anna Keynes, first-class; Samuel Bartlett, second-class; Maggie, second-class; Regularity, second-class. Mr. Burgess, Chelsea: Chelsea Hero, second-class. Mr. Turner: Prince of Wales, second-class. Mr. Legge, Edmonton: Roundhead, second-class; Enchantress, second-class; White Perfection, first-class; The Bride, first-class. Mr. Collier: Annie, second-class. Mr. Hopkins: Brunette, second-class. Mr. Perry, Birmingham: Sylph, second-class.

Messrs. E. G. Henderson, Wellington Road, exhibited a large and beautiful collection of the Pomponne Dahlias, some of them but a little larger than a Ranunculus, and as perfect in form. Beautiful and delicate in their colour and markings, they were much and deservedly admired. A special certificate was awarded them.

Messrs. Henderson exhibited also a very extensive and interesting collection of their far-famed variegated-foliaged Pelargoniums. Of this collection it is impossible to speak too highly. It was a great privilege for those who are now giving their attention to this interesting section of Pelargoniums (which we hope to see duly represented in our exhibition schedules for 1864), to have an opportunity of seeing so many and such good and distinct varieties brought together. We shall give their names for the benefit of those who did not see them, but who may feel anxious to lose no time in adding some of the best kinds to their collection:—Silver Chain, Lucy Grieve, Goldfinch, Miss Emily Dunelle, Rosette, Golden Harkaway, Snowflake, Mrs. Benyon, Golden Chain, Oriana Improved, Mrs. Pollock, Italia Unita, and a group of seedlings not yet named. A special certificate was awarded this most beautiful collection.

Some blossoms of Fuchsias from the collection of E. Banks, Esq., were sent by the same firm; they were extremely beautiful, and decidedly in advance of the Fuchsias of the present day. It would have been more satisfactory to have seen the plants; but the flowers, numbered 21, 46, 17, were all first-class, and if of good habit double-firsts—20, 40, 24 not being far behind them.

Phytolacca decandra foliis variegatis, also from Messrs. Henderson, received a label of commendation; *Centaurea argentea*, a very finely-cut foliaged plant of dwarf habit, suitable for the edging of beds, and superior for the purpose to *Centaurea gymnocarpa* and *Centaurea candidissima*, first-class certificate.

Mr. Salter exhibited a collection of bedding plants, which were arranged to form a flower-bed, the background consisting of summer-flowering *Pompona Chrysanthemums*. The plants used were *Centaurea candidissima* and *gymnocarpa*, *Veronica incana*, *Oxalis rubra*, *Tussilago farfara* foliis variegatis, and *Amaranthus melancholicus*. Mr. Salter sent also a plant of *Gazania splendens* foliis variegatis, adding one more to his extensive and interesting collection of variegated-foliaged plants.

Mr. Saltmarsh, Chelmsford, sent scarlet *Pelargonium* Princess Alexandra, deep rose, flowers in a large truss, but not of sufficient quality. *Pelargonium* Luna, a promising variety, with golden foliage and marked with dark reddish-brown zones. Plants from cuttings will better decide its merits; it too much resembles Mrs. Milford. *Pelargonium* Little Treasure, small zonate foliage, bright scarlet flowers—the specimen exhibited was too old to enable any decision to be arrived at, some portion of the old plant producing very small foliage, while the younger shoots displayed a much more vigorous habit. It should be sent again, and will probably form one of the family of Mr. Cowper and Waltham Pet.

Mr. Banks, Sholden Lodge, sent a seedling *Verbena* Lady Palmerston; but no advance upon better varieties.

Messrs. Smith, Dulwich, sent seedling *Pelargoniums* Excellent, a useful kind for bedding purposes, a pale rosy salmon; Silver Chain, a fine white-bordered foliage variety; *Pelargonium* Favourite, white deep-bordered foliage variety—younger plants of these two promising plants will more fully display their merits; *Pelargonium* Peacock, a variegated-foliaged plant. *Anemone japonica* Honorine Jobert, a useful hardy border plant, the flowers resembling *A. vitifolia*—commended.

Messrs. Carter sent a collection of annuals, consisting of *Asters*, *Marigolds*, in all sizes and colours, *Helichrysums*, and some very fine double *Zinnias*.

Messrs. Veitch sent a beautiful collection of plants, among them three seedling hybrid *Orchids*, raised by their persevering foreman Mr. Dominy; *Cattleya exoniensis*, a very beautiful late-flowering variety with pale blush flowers, the lower lip being marked with a deep rosy purple band, which terminates midway on the surface of the lip in a straight line, producing a very singular effect—second-class certificate. The other hybrids, *picta* and *hybrida*, have been described before. Among the other plants was a fine specimen of *Odontoglossum grande* covered with its peculiarly-tinted flowers, two specimens of *Lilium auratum*, *Lilium neilgheriense*, *Alocasia zebrina*, *Sciadopitys verticillata*, *Bambusa variegata*, *Dracaena ferrea*, &c.

Mr. Bull, Chelsea, also sent a large collection of interesting plants:—*Adiantum cardiophyllum*, not a new plant, first-class certificate; *Pteris pellicula*, a very handsome Fern, first-class certificate; three varieties of *Caladium*; *Schizocasia Portei*, a form of *Alocasia* with a widely jagged cut leaf, which when in better condition will certainly prove a useful and ornamental plant; *Gesnera velutina*, with dark refulgent foliage; *Cupressus Barkeri*; *Adiantum* (*Cheilanthes*?) *radiatum*; *Drosera dichotoma*; *Areca* species, a very handsome Palm with deeply ribbed foliage, and many others. Mr. Bull sent also six cut specimens of *Pentstemons*.

From Messrs. A. Henderson & Co., Pine Apple Place, came a fine specimen of the Cotton-plant with its seed-vessels in all their stages, and when expanded displaying the growth of the valuable article of commerce.

Mr. Dean, Shipley, sent a fine plant of *Cionidium Moorii*, a very beautiful Fern—first-class certificate.

Mr. Standish, Ascot, sent six seedling *Gladioli*, four of which received certificates; Randle Jackson, bright carmine, commended; Charles Davis, a rosy-tinted scarlet, second-class certificate; Mrs. Dix, a beautiful white with pale pink blotches on the upper petals, lower petals feathered with bright crimson purple—this will prove a first-rate flower—commended; Etna, very bright light scarlet, commended. These flowers were exhibited in Mr. Standish's stand of twenty-four varieties. They would have made a better appearance had they been shown singly as seedlings. We noticed one very fine seedling, *Prospero* in Mr. Sladden's stand of twelve *Gladioli*. The *Gladioli* are not so fine as they were in 1861. Mr. Youell's fine collection was inferior to what we have seen—the individual flowers had not attained their usual size.

There were no seedling *Hollyhocks*. The miserable appear-

ance of stands of single flowers gave everybody the horrors. What is the beauty of the *Hollyhock*? Its magnificent and graceful spikes of flowers. Why, then, deprive this splendid garden ornament of its honours by exhibiting single flowers, which reminded us of the three pips of *Auriculas* at the Spring Exhibition in the Botanic Gardens, Regent's Park, 1862, which brought down such ridicule on the exhibitors? We trust the *Hollyhock* will be shown in 1864 in all its primitive splendour and grandeur.

FRUIT COMMITTEE.—Only a Sub-Committee met on this occasion, consequently no certificates were awarded. The most important object brought forward was a new Grape from Messrs. Lucombe, Pince, & Co., of Exeter, called Mrs. Pince Black Muscat Grape. The Committee were unanimous in considering it a Grape of great promise; but, failing in detecting a sufficient muscat flavour, wished to see it again when it could be examined in full Committee.

From Mr. Tillery, Welbeck, came a seedling White Grape raised from the Trebbiano, and said to be earlier than the Black Hamburgh; also a bunch of Welbeck Black Tripoli, which always colours and is of very fine flavour. It was considered to be the true Black Hamburgh.

Mr. Rust, gardener to the Right Hon. Lawrence Sullivan, Fulham, had a seedling Peach raised from Late Admirable. The fruit was large, yellow tinged with orange, but had not arrived at perfection.

Mr. Bailey, of Shardeloes, sent a seedling Nectarine called the Shardeloes Nectarine. In shape it resembled the *Violette Hâtive*, and in colour was darker than the *Eldrage*. The Committee were of opinion that it was not better than the first-named kind.

A very good early White Grape of the Sweetwater breed came from Mr. Brown, gardener to Sir C. Knightley, Fawsley Park; and Mr. Melville, Dalmeny Park, sent a new Grape, which was large-berried, grizzly or amber-coloured, very sugary, and rich, but its colour was objected to.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE season has been very favourable for operations under this head. Weeds could with half the usual trouble have been quite eradicated. Potatoes and other crops are coming off early, so that the process of manuring and trenching may be prosecuted at every favourable opportunity. As a general rule, it is recommended to mark the trenches 4 feet wide to throw up good-sized steep ridges. It is not advisable, if it can possibly be avoided, to dig the ground intended for general cropping one spit deep, even if the soil be shallow and the subsoil ungenial. It is much better to remove the top and to well break up the bottom of the trenches; depend upon it these operations pay for a little extra trouble, and now is the time to commence them. *Artichokes* (*Globe*), cut off the stems as fast as the heads are used. *Broccoli*, earth-up the plants as they advance, it greatly promotes their growth; also, earth-up other plants that require it. Keep a watchful eye for the caterpillars. As soon as they are observed have them gathered off by hand, this being the only sure means of eradication. Remove all dead and decaying leaves from the *Brassica* tribe in general, to some ground under the process of trenching. *Carrots*, sow a few Early Horn in a sheltered place to stand the winter. *Celery*, the first earthing-up of the crop should not take place until it has made considerable progress. By commencing too early it is drawn up weakly, the earth to be closed round the stalks with the hand. *Endive*, tie-up for blanching when the plants are quite dry. Another plantation may also be made. *Onions*, a few Welsh sown now may come in useful where such things are in constant request. *Potatoes*, when the haulm is ripe to be taken up, as they are likely to grow again if showery weather continue, which will greatly deteriorate their flavour.

FLOWER GARDEN.

The favourable change in the weather will now enable those to proceed vigorously in their operations who intend making alterations or new arrangements in this department. As regards the formation of new plantations or the removal of large specimens, see that the ground has been prepared for the reception of the plants by trenching, and draining if the soil be moist and damp; for want of attention

to this, and especially to trenching the soil, the labour has in many instances been completely lost. Omit the barbarous mode too frequently practised of cutting off large portions of the roots. Whether the plants be large or small, be sure that the hole in which each is to be placed is large enough in its circumference to allow sufficient room for laying out the roots regularly and at full length in a horizontal position previous to covering them with soil. Deep planting too must also be avoided: rather have recourse to stakes to keep the plants steady, than that they should be sunk in the ground to such a depth as to insure slow but ultimately certain death. The four conditions necessary for success are—the trenching of the soil, the preservation and the regular distribution of the roots, and shallow planting. Sow the following annuals now on rather poor soil, and give them a top-dressing of manure in February, they will then flower freely in May and June. *Nemophila insignis*, *Collinsia bicolor* and *grandiflora*, *Godetia Lindleyana*, *rubicunda*, and *tenuifolia*, *Clarkia pulchella* and *alba*, *Eucharidium grandiflorum*, *Lupinus nanus*, *Gilia tricolor*, *Leptosiphon androsaceus* and *densiflorus*, and *Viscaria oculata*. All other hardy annuals may be sown about the middle of March.

FRUIT GARDEN.

Apples and Pears will now require constant watching to catch the favourable time for gathering, which must be as soon as they are detached from the shoot easily without using force. The plan of laying them in heaps to sweat, as it is called, will not answer for such as are required to be kept long, as it hastens the ripening process too much, and as a consequence decay will soon follow. Old Strawberry-beds intended to be left another season should have the runners and rubbish cleared out from them, and be well dressed with rich decomposed manure, but do not mow off the leaves. Strawberry plants in pots must not be allowed to be very dry, nor ought they to be drenched with too much water.

GREENHOUSE AND CONSERVATORY.

One of the first operations claiming attention at the present time is that of potting the bulbs, as much of the success of early forcing depends upon early potting. We never saw bulbs in finer condition than they are this season; they are not only large but sound and perfectly matured. Pinks and Violets must also be looked to; the latter, both for planting and blooming, to be planted out in a frame or pit. Remove those Azaleas which have set their blooms to the greenhouse, but the later kinds to remain in heat until the growth is matured and the bloom set. The greenhouse, if not already done, should be prepared immediately to receive the plants, as if we should have a return of the late frosty mornings, it will be advisable to house them without delay. In preparing the house let every part of the brickwork be lime-whited and the woodwork well scrubbed with soap and water and afterwards syringed with boiling water, to dislodge spiders and destroy the eggs of insects which have been deposited in the crevices of the wood, and look to the flues or hot-water apparatus, and see that everything is ready should severe frost come unexpectedly upon us. Have all the pots washed clean, and tie such plants as require it, so that there may be no delay in housing the plants should a change of weather render it necessary. Keep the structures open night and day after the plants are placed in them, only reducing the ventilation when unfavourable changes in the weather take place, and even then with particular moderation and caution, if sturdiness and blooming in mature perfection at the proper season are aimed at.

STOVE.

A certain and gradual reduction of temperature corresponding to the decline of external heat should be commenced. The plants will thus be prepared to withstand the prolonged gloom of the winter season. In the treatment of stove plants it is surely an error to act independently of exterior circumstances. The season and, in fact, variations of temperature, should be allowed in a certain and reasonable degree to exert their legitimate influence. Top-dress any plants that may require it, and see well to the drainage of all, especially established plants that have not been repotted for a considerable time.

PITS AND FRAMES.

Plants which have made their season's growth should be

freely exposed to sun and air on every favourable opportunity in order that the wood may be well ripened; but such as are still in free growth should be encouraged by every possible means while fine weather continues, keeping them rather close, guarding them carefully from cold winds, and giving a liberal supply of heated water at the roots. If anything requires pot room let such be shifted as early as convenient, keeping the atmosphere rather close, and watering very cautiously for some time afterwards until the roots take hold of the fresh soil.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Run the hoe through all advancing crops. Laid down some rather leggy Broccoli, so as to have the earth close up to the stem. Hoed young Lettuces, Spinach, and Onions. Took off the late Onion crop, not individually so large as usual owing to the dry season; and yet we have scarcely enough of those sowed for buttons, for our ground is too strong for growing them small, firm, and round as a marble, as we like to see pickled Onions, though we dare not eat them, for if we did our coat would have the odour of them for a month. The main crops of Onions will be strung on a wet day; and for this purpose, instead of depending on the stems plaited together alone, we generally have two or three stout straws of wheat plaited along with the stems. Onions so plaited in strings are very handy for taking into the kitchen, more especially if the bulbs are arranged in strings of the large, larger, and largest. If these are strung up dry, and kept dry, it matters but little where they are housed. We have seen fine close rooms made for Onions, and the chief advantage of such a place is that they grow and push out too early in spring. No place is better for them than an open shed, if thatched all the better. We have never known any amount of cold injure an Onion, provided it was kept dry. At least we have seen strings hanging against the wall of an open shed with the thermometer close on zero, and the Onions not injured in the least. A full-grown specimen is easily injured by extremes of temperature when subjected to alternations of wetness and dryness.

Housed all our early Potatoes in good condition; not a vestige of the disease to be seen, but we are not safe yet, as two years ago we harvested a beautiful lot without a speck, and in two months the sound ones had to be picked out. Cleared off decayed haulm of Peas as it became useless. Watered Cauliflower, the rain not having penetrated to the roots.

Earthed-up a little more Celery just to have enough to go on with, and have reason to be more and more satisfied with the Incomparable White Dwarf sent out, we think, first by Mr. Turner, of Slough. We have had immense Celery in September, and yet it did not please us half so much as this little kind. It is true we had a few gorgeous heads of the former to make people stare, but unless we covered it from autumn rains the very size of the plants kept the rains in their hearts, and caused the water to putrify and discolour the centre, if not to rot it outright. Here there is no such chance with our Incomparable friend. We can grow two or three plants for one of our old Giants; and if we grow the single plant as thick as our arm and 15 inches high, we can send a foot of beautiful, sweet, crisp Celery to table; and so long as people keep saying, "Never tasted such beautiful crisp Celery," we mean to keep to the Dwarf, and save the immense banks of earthing-up for all the Giants. Seriously, to all amateurs with little room we would say, Have your own Celery fresh for your cheese by growing the Incomparable. We find that some of our great gardeners in the north use it for the spring crops, because it is so hardy and dwarf; we should be inclined to give it the post of honour at all seasons. In general we must own we have been annoyed with Giant Celery. It passes through so many hands, from the gardener to the employer of the gardener, that it becomes reduced to a very little bit, and is so pared and pared again that a lover of Celery scarcely knows what is before him. Mind, we do not blame any one. Those who send up a tiny piece fit for a sparrow out of a bold stick of Celery do so from use and wont, and, as they think, for

the best. It often tells, however, against the growers. We know of one case where there was no end of grumbling about the Celery for cheese, but the employer and his friends happened to pass the vegetable-washing shed one day, and were quite enraptured with the Celery, and as instructions were given that the Celery should go to table exactly as it came from the gardener's hand, he has never heard a word about it from that day to this. A similar bother took place in another garden as to Sea-kale. Of course when blanched and about 6 inches high we expect the whole head as cut to form part of the dish that is sent to table; but the artiste of the kitchen was far too ethereal for such mundane treatment, and cleared all away but the little knob in the centre. The garden being little more than an acre in extent, no wonder that there were everlasting grumbings in the winter as to the deficiency of Sea-kale. What would have made six or eight good dishes cooked in the ordinary way for a good party, would not have made one in this *recherché* particular way; and so the grumbling went on until a great gardener was called in to give his opinion on the matter, and he candidly stated that thus treated, the whole garden put under Sea-kale could not yield a supply above six weeks. With such a mode of dressing and cooking it would hardly be possible for any gardener, except he had acres of Sea-kale, to be able to act on our favourite rule, which is to keep friends with the cook by always having plenty, and if at all scarce of anything, keep the knowledge of that scarcity to ourselves. To our young friends we would say that all this, to be done well, must be done in such a way that courtesy and a desire to oblige must ever appear paramount to fineness, and quite as transparent as integrity of character. We should feel we had not lived in vain could we impress our brethren with the vast difference conveyed with the words, "You must do," and "You will oblige by doing." A little courtesy does much to render pleasant the pathway of existence.

Other matters as to Mushrooms, Cucumbers, and other vegetables, much as before stated. The Mushrooms in our little beds have been so good that we have had no occasion to hunt the meadows. We are not much given to such dainties, but as the question is often asked as to the superiority of one kind of Mushroom over another, we must say that for our own eating we would much prefer those grown under our own care to any gathered from a pasture. We find that the cakes of spawn, especially the thin ones that Mr. Forsyth recommended to us as better than the thick ones, will soon do for spawning. We will make these cakes or bricks after this. This, though a small case, just illustrates the advantage not only of gardeners meeting each other, but the advantage that the employers of gardeners derive from their gardeners having an opportunity of comparing notes with their fellow gardeners. We are quite delighted to find that from various remarks on this subject in the *Journal* many gentlemen have not only given their gardeners the necessary time to make a tour and see what they could, but have also defrayed part or whole of the expenses. One most worthy man that called here had two five pounds put into his hands on leaving, and was told where to apply in London when that ran out. We feel sure that the money so spent will be seen in improvements many years hence.

FRUIT GARDEN.

Much the same as previous weeks. Find that since the rains Pears and Apples are increasing in size wonderfully, though some even now would be better of a little water at the roots to the extent of half a dozen of water-pails to a small standard tree. Figs are bearing well outside. Some in pots will be taken to a warmer place. Melons have had fresh linings given to those in frames, and others in pits have had the fruit elevated to keep them from cracking with the damp. More air and fire heat have been given to Grapes, not only to ripen late Grapes, but to keep them sound and free from damp. In some very warm days, with a powerful sun, the floors, stages, &c., were slightly syringed with pure water to prevent the house becoming too dry, as that has a tendency to make Grapes quite ripe to slightly shrivel. Attended to Strawberry-pots for forcing. Went on clearing those in the open air. Gathered fruit as it ripened. Find that Peaches and Nectarines in the open air will be over before their usual time this season. The Apples

chiefly in use for table are the Red Quarrenden, the Kerry Pippin, and the Strawberry Pippin. The Pears are chiefly Jargonelle and Williams' Bon Chrétien. The latter, with frequent gatherings of the largest, we manage to have in use at least six weeks or two months.

ORNAMENTAL DEPARTMENT.

Fresh arranged conservatory. Rolled walks and lawn. Picked over flower-beds, still beautiful. Tied-up tall plants. Picked off the flowers of Dahlias that had suffered from the drought. Put in cuttings of Geraniums as fast as we could get at them, so as not to injure the outline of the beds. Picked faded flowers from vases. Watered with manure water large Chrysanthemums in pots. Those who wish early Hyacinths and Tulips, should pot them as soon as possible in good loam, a little very rotten leaf mould, and a little silver sand. We prefer, instead of using much manure for such things in the soil, to use rich top-dressings and manure waterings. Those who wish an early display of bulbs for the flower garden should buy them as soon as possible. Place them on a north border, 3 or 4 inches apart, for Hyacinths, Narcissus, Tulips, and cover with 4 inches of loam and leaf mould. When the flower-beds are all cleared of their summer residents, well dug, and pulverised, these bulbs may be lited in balls and planted, and never feel the moving. Moved a lot of Cassia corymbosa into a deeper pit to give more room. These were struck this spring. This is a splendid orange colour, either for out-door adornment in summer or conservatory-flowering at any time. Repotted Chinese Primulas into 32-sized or six-inch pots, ditto with Cinerarias for early blooming. Pricked off younger seedlings of Primulas and Cinerarias for succession, also herbaceous Calceolarias. Gathered seed of shrubby Calceolaria from beds, which seems more mature than usual. Syringed Violets in pots and beds with sulphur water, to disperse all trace of the red spider. Find that there was a mistake last week as to Geranium cuttings being an inch in size, as, though small, they are mostly above that size. They are planted about 1 inch apart. The tenderest of these are placed under glass, and to prevent shading they have a skiff from the syringe in the heat of a sunny day. The same as respects Verbena cuttings. A little damping of the foliage in the middle of the day is often much better than much shading. There would be fewer mischances did we always recollect that shading, if necessary, is a necessary evil. The good propagator will give it only when necessary, and remove it as soon as the cuttings or the plants can do without it. Took Camellias into the house; and Heaths, Epacris, and the better greenhouse plants should no longer be exposed to the lashing rains of autumn. —R. F.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross.—*Descriptive List of Strawberries and Grape Vines.*

Barr & Sugden, 12, King Street, Covent Garden.—*Floral Guide to Winter and Spring Gardening.* 1863.

F. & A. Dickson & Sons, 106, Eastgate Street and Upton Nurseries, Chester.—*Catalogue of Dutch Flower Roots.* September, 1863.

B. J. Edwards, 222, Strand, London.—*Autumn Catalogue of Hyacinths and other Bulbs.*

COVENT GARDEN MARKET.—SEPT 12.

Fruit and vegetables of all kinds continue plentiful, and in all respects the supply of the different kinds, as well as their prices, differ little from last week. Grapes, Pine Apples, and Melons are in abundance. Some Marie Louise and Louise Bonne of Jersey Pears are making their appearance; also Ribston Pippins, which promise well. Of other dessert Apples the supply is rather short. Filberts and Cobs have somewhat declined in price; the latter may be obtained in excellent condition at from 45s. to 50s. per 100 lbs. The Potato market is still heavy. Flowers the same as last week.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

TRITOMA UVARIA CULTURE (J. L.).—*Tritoma uvaria* requires nothing that we know of beyond a deep, rich and moist soil to induce it to flower. It flowers freely with us in the early part of October. We should say your fine healthy plant will yet flower, the latter part of August being quite early enough, even for East Cornwall, to look for the flower-spike of this plant. We should think it is quite hardy with you; but a few inches of cocoa-nut fibre put over the crown on the approach of severe weather will make all safe. Remove the offsets in the spring immediately on the plant commencing new growth.

GLADIOLUS DISEASE (An Old Subscriber).—Your flower was smashed. Our correspondent says, "*Campanula garganica* is a good trailer."

COMPOST FOR GERANIUMS—CUTTINGS OF BEDDING PLANTS (An Amateur).—We think your compost well aired and turned might do very well for Geraniums, &c., in small pots; but for larger plants we should be doubtful unless we saw it. Much will depend on the sifting and the sweetness. We would not be liberal with dung or soot until fairly tried. We suspect your cuttings have been kept too close and too moist. We can hardly advise you how to succeed with them and the Grapes too, as too much damp will also injure the Grapes; but instead of planting we would advise you to put the cuttings in pots, and then you can more easily move them.

SEEDLING PRIMULAS (Idem).—The *Primula sinensis* if potted now, four in a small pot round the sides, and in a month or six weeks potted singly, will flower nicely next spring.

PREVENTING ENCRUSTATION IN BOILERS (J. Kearns).—We know of no better remedy than salt ammoniac, an ounce to sixty gallons of water, but the oftener the boiler is emptied the better. We think if potash or soda were mixed with the water and allowed to stand several days before being put into the boiler, that the evil would be lessened; but then it might not suit the purposes for which the boiler is used. All boilers will become encrusted with such water.

COCOA-NUT REFUSE FOR POTTING (J. L.).—Cocoa-nut dust is a good material for plants of any kind, from a Pine down to a Strawberry, and from an Orchid to a Calceolaria. All plants thrive well in it.

HEATING A SMALL HOUSE AND CUCUMBER-BED (O. H.).—The pipes in the bed had better be covered with 6 inches or so of rough rubble, clinkers, &c., and then an inch or two of fine washed gravel—leaving only the blue little stones. An inch of cement might go over this so as to give you a smooth firm bottom, then about 15 inches of soil. If you go deeper with the pipes they will be less effectual. For such a house and to have fruit so early we would like three four-inch pipes on each side for top heat and on the same level.

TRUS SUCCEDANEA (Sumach).—Unless under very favourable circumstances we fear this effective plant will not prove quite hardy with you. It is, however, well worthy of a trial in some of the lovely sheltered corners in the upper part of your unique grounds, or on a conservatory wall. A hot position with a light dry soil are the most likely conditions to that proper ripening of the wood, which with slight protection, may enable it to stand the winters of Bucks. But you are too well informed on all these matters to require any instructions for your guidance. We shall be happy to hear how it succeeds with you.

DISEASED VINES (B. A. S.).—You have a fungous rust on the Vines, the result of over-moisture at the roots, or an over-close moist atmosphere in the house. The first remedy is more air and heat in the house, a little sulphur on the walls or the heating medium, and it that does not answer, lifting the Vines or more drainage.

HARDINESS OF CUPHEAS (J. L.).—*Cuphea eminens* and the *Crystal Palace* crimson are probably hardy in East Cornwall. Try them. Cupheas in pots require about as much water as a Fuchsia—just enough to keep them growing in winter, but abundance when growing and flowering in summer.

UNHEALTHY ORANGE TREE—HOYA BELLA (C. Churchill).—We think the excessive flowering of the Orange and the bad health afterwards are owing to dryness at the roots. Soak the whole ball in a tub, allow it to drain afterwards, and until growing freely use nothing but clear soft water. In spring give all the heat you can, so as to promote free growth. Keep rather dry in winter. Strong manure now is like presenting beef-steaks to a poor invalid who can only sip a little liquid. You may allow the *Hoya* to bloom, but take it to the warmest end of the greenhouse and keep it rather dry all the winter, keeping the stems succulent by syringing them frequently, rather than by giving much water at the roots.

TEMPORARY HEATING A SMALL GREENHOUSE (P. J. M. F.).—The paraffin lamps will be better than the candles; but two would be of little use in a severe night and no protection used. We would recommend as the simplest and best, a small iron stove with a wrought iron tube through the roof, and a flat top, so that you may place a vessel or vessels of water over it. We think the plants will be safer in pots or boxes set on the border, instead of being planted out in such circumstances. You can more easily examine, move, and do what is wanted to them. A stove about 30s. complete ought to do all you want. If the fire-box is free of the sides so much the better.

SHELF FOR GREENHOUSE (Mrs. West).—You cannot do well with less than 2 feet clear round the fountain. The end shelves or platforms may range from 2½ to 3 and 4 feet in width. You would see the whole matter referred to the other week. The plants will not suffer from the air being admitted as proposed, but it must be done moderately at the sides in cold weather. The air at the top would then be the principal thing.

HEATING A SPAN-ROOFED FORCING-PIT (Yorkshire Subscriber).—The cheapest plan would be to take a strong flue along the centre and make the top of the flue the pathway. The best way would be to take two four-inch pipes round the house for top heat, and continue the linings as now. You will find much in the present and late Numbers to suit your case. Of course if you wish two hotbeds, one on each side, the best plan would be to have two pipes on each side for bottom heat, and two for top heat.

DENDROBIUM CHRYSANTHUM TREATMENT (Orchidophilus).—You had better give a little warm water now to the *Dendrobium*, but not much until a good many buds are opening.

COKE FOR HEATING (Idem).—There will be no difficulty as to the coke; if broken small and a damper used it will keep alight quite as long as coal, and after lighting there need be little smoke. This will be lessened by introducing a small stream of air, by pipe or otherwise, over the fire-place.

STACHYS PALUSTRIS AS A SUBSTITUTE FOR ASPARAGUS (Stachys palustris).

—This is a native, deciduous, herbaceous plant, growing 2 feet high, and has purple flowers in August. It is commonly known as Marsh Woundwort, or Clown's All-heal. The root is tuberous, and is used in the non-corn-producing countries of Northern Europe as a substitute for bread in times of scarcity. Dr. Hogg, in his "Vegetable Kingdom," says, "The tubers contain a large quantity of nutritive fecula, which is made into bread in the north of Europe in times of scarcity, and from which starch can be obtained. These were called by the old writers *Panax colona*. The underground stems are of the size of small Asparagus, and are eatable." We have not seen the stems of this plant used so extensively as the young shoots of the Wild Hop (*Humulus lupulus*), as Greens by country people, though we have known some do so, and they pronounce them to be delicious. We have eaten the shoots of the wild and cultivated Hop after being boiled like Asparagus, and like them better than woody Asparagus with about an inch of eatable head to suck, and consider them equal to it when the Asparagus is eatable its entire length as it ought to be, and as Hop-buds, as country rustics term them, always are. The plant in question grows naturally in moist low pastures or meadows, and so requires a moist soil to grow in. Were we going to cultivate it we should dig the ground deeply, even trenching it 2 feet deep, and when this was done cover the plot with manure 6 inches thick, and fork it in, and divide the ground into beds 4 feet wide, pointing north and south, with two-feet alleys between the beds, driving a stake at each corner of the beds. We would then place the roots on the surface, a row along the centre 1 foot 6 inches from plant to plant, and the like distance between the rows, placing the plants in the outer rows in quincunx arrangement. Throw out the alleys over the beds, covering them 3 inches with soil above the crowns of the plant, levelling the surface with the spade, but not beating it. The best time to plant would be in March. The plants would need watering copiously in dry weather, and weeds to be removed at all times when they appear. The stalks to be cut off in the autumn after they decay, and 6 inches of partially decayed leaves spread over the beds. The stems would strike through the leaf mould in the spring, when they would be cut off 6 or 8 inches below the surface, similar to Asparagus, and boiled and served up in the same way. We have no doubt that *Stachys palustris* which has stems as thick as small Asparagus in a wild state, would become the thickness of well-grown Asparagus shoots by liberal treatment, just as Asparagus itself, Sea-kale, and many other plants, which were used from time immemorial, by the rustic population, have become under cultivation the pride of the dinner-table, and of so much import to man as to become articles of commercial importance. The plant would not thrive in light dry soil unless it were very rich, and watered abundantly in dry weather; but in such soils the Hop grows freely, and gives a supply of shoots, which might become finer and larger by cultivation, that are not inferior in tenderness and flavour to any vegetable we possess. The best way to obtain plants would be to apply to some friend in the country, or a dealer in herbs would probably obtain them for you. We have heard the same tale about Chestnut leaves being poisonous, but have used them without any deleterious results. Oak, Beech, &c., make the best leaf mould, but there is not so much difference after all between the leaves of one tree and that of another genus after they become decomposed. Leaf mould from Chestnut leaves contains more potash than any other; but in other respects it does not differ materially. Some people say manure poisons coniferous trees; and, probably, the same people will tell you that Chestnut-tree leaves are poisonous to any plant to which they are applied. We advise you to try them.

NAMES OF FRUIT (W. N. S.).—You should have sent the leaves as well as the fruit of your Peaches and Nectarines, as the character of the glands is very important in determining the names. 1 appears to be Royal Gorge; 2 was too much bruised; 3 a Clingstone Nectarine, apparently Newington; 4, hard and unripe; 5 and 7, Bellegrave; 6, Nobleess; 8, Grosse Mignonne; 9, Elruge. (W. Harrison).—Your Plum, which arrived in very bad condition, is the Diamond. (Old Subscriber).—We cannot undertake to name so many as thirty sorts of unripe Apples. Correspondents must be reasonable in their demands upon our time in this respect. 31, 32, Royal Muscadine.

HEATING A VINERY (T. H. L.).—Your plan will answer admirably for pot Vines; but unless you make your flue wide enough, so as to borrow top heat for the house from it, you will not be greatly better-off for your early ripening of the general crop. We think you may do so. No plan could be worse than having a tier of flues against the back wall only. You have also a fine opportunity of renewing your vinery by planting in that border outside, and then making openings in your outside wall. If the house is wide you might shut-in a part longitudinally, so as to forward the Vines in pots before forcing the others. Glazed earthenware pipes are capital for heating where you can place them on the level, and where they are not likely to be injured by clumsy labourers. Mr. Niven, of Drumcondra, and others use them largely.

MADAME VAUCHER GERANIUM (Devoniensis).—If you supply Madame Vaucher Geranium liberally with water at the root it will prevent it from turning pink when planted out. When turned out of pots such plants are apt to suffer from dryness at the root till they take hold of the ground, and we know that when exposed to drought this Geranium assumes a pink shade; but so soon as the ground is well watered it regains its usual colour.

DESTROYING WOOLLYCE (A. B. C.).—If you can pour boiling water into crevices between the brickwork and wooden framework, it will certainly destroy your troublesome pests. If it is not possible to introduce boiling water into the haunts of the woollice, the most effectual way will be to raise the framework and destroy all of them that you possibly can; and then scrape away all the loose mortar, and bed the woodwork firmly down on to a layer of Portland or Roman cement, so that every crevice may be filled up and defy their making use of such a retreat. To destroy the stragglers that may have taken up their quarters inside the frame, boiling water may be applied to the inside of the walls, on which they are generally found creeping, after dark. Poisoned fruit, such as Pears or Peaches, laid in the frame at night will also destroy them, as they are fond of feeding on fruit. Toads are great enemies to them, and one or two such lodgers will make short work of great numbers of them. Any or all of these remedies will enable you to overcome your marauders.

FRUIT TREES FOR POT-CULTURE (A. B. C.).—The following varieties of fruit trees for pots will answer your purpose:—*Apricots*.—Moorpark, Royal, Large Red. *Peaches*.—Early York, Royal George, Violette Hative, Noblesse, Walburton Admirable. *Nectarines*.—Violette Hative, Pimston Orange, Elrège. *Plums*.—Green Gage, Kirke's Seedling, Jefferson, Cox's Golden Drop. *Grapes*.—Royal Muscadine, Black Hamburgh, Chaptal. Although you do not ask for advice regarding the arrangement you propose in the cultivation of these fruits in pots, having at the same time Vines trained over them near the glass, it may be remarked that in order to succeed with the fruit in pots the Vines over them must be trained much wider apart than is usual when a house is devoted to the growth of Grapes entirely, otherwise the fruit trees in pots will not receive that amount of light and air necessary to their well-doing. If possible it would be much more satisfactory if the trees in pots could have a division entirely to themselves. It will not be easy to succeed with them; and, at the same time, secure a crop of early Grapes over them.

GNAPHALIUM LANATUM (N. W. B.).—*Gnaphalium lanatum* is a hardy herbaceous plant, therefore likely to stand the winters of Norfolk.

RUSSELLA JUNCEA CULTURE (Idem).—*Russelia juncea* is a stove plant from Mexico, and one of the most graceful plants in cultivation. It requires a compost of equal parts turfy loam and fibry peat, chopped with a spade, but not sifted unless through a riddle with inch meshes, and a liberal admixture of silver sand. We presume yours is a small plant; if so, pot it and keep it in a moist atmosphere to induce free but not luxuriant growth. Shift into a pot a size larger immediately the roots reach the sides of the pot. Repeat the same until the plant attains the size you wish, when you will give the last shift, double the sized pot of any of the former being employed. When this pot becomes full or roots the plant will show flowers; but much will depend on pinching the strong shoots back when they are a foot in length. The branches may be tied to a stick, from which the laterals droop gracefully. It flowers more abundantly on moderate than luxuriant growths. You will, therefore, stop all strong and rampant growths, encouraging the weaker until growth begins to slacken, when stopping will be discontinued and syringing too, the plant being kept drier at the root and less moisture given above. Any straggling blooms to be removed if they appear whilst it is growing. Sudden changes of temperature are inimical to its well-being; and it rarely does well after flowering once, consequently young plants must be ready to grow on to supply a worn-out specimen. It is easily propagated, either by single joints or the shoots or cuttings in a little bottom heat, or from suckers and division.

TUBEROUS TROPÆOLINS (E. L. C.).—The seeds of tuberous-rooted *Tropæolins* are best sown immediately after they are ripe in sandy peat and loam in a Cucumber-frame, or where a bottom heat of about 75° prevails—top heat about the same. The seeds are best placed separately in thumb pots, for they can then be shifted into larger pots as they advance in growth without disturbing the roots. When the plants are fairly up remove them to a warm greenhouse and near the glass, placing a small stick for the plant to climb up in the pot. The seedlings will need but one shift the first year, say into a 48-sized pot. When they have grown as much as they will and the leaves begin to turn yellow, lessen the supply of water, gradually dry them off, and give them a rest of three months by keeping the tubers dry in a cool place. Pot early in September in after-years, and grow in a warm greenhouse, giving abundance of air and all the light practicable. *Tropæolum tricolor* usually commences growing in September, growing on through the winter and flowering in April in the greenhouse; dying down immediately after flowering, when the pot may be laid aside until September in a dry cool place. It is then to be potted and trained on a fan-shaped or some other trellis. The seed may be sown now in a little heat not more than 75°, nor less than 65°, or early in February on a gentle hot-bed; but it is best to sow them immediately they are ripe.

GARDEN-PLAN.—(*Aster*).—We are sorry that we can only reply to you, as we have replied to others—we never arrange the planting, or recommend the plants to be employed. We only criticise what our correspondents propose doing, and point out their errors, if any.

ALOCASIA METALLICA (C. S. N.).—You will find an article on this plant in another column.

PORTRAITS OF FLOWERS.—(*N.*).—"The Botanical Magazine," "The Floral Magazine," and "The Florist and Pomologist," are all published monthly, and furnish coloured portraits of flowers and fruits.

POKE (B. A. S.).—In the Southern States of America it is cultivated for use as Asparagus and Spinach, and a very nice vegetable it is. If you were to take a stroll in the morning into some market—say New Orleans, you would be led to exclaim, "What is this we have stacked-up here?"—E. B. STENCE.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*T. F.*).—Your Ferns are—1, *Adiantum asmilie*; 2, *Adiantum tenellum*; 3, One of the *Dennstaedias* (*Dicksonia*), and apparently *D. nitidula*; 4, *Neprolepis exaltata*. (*Tyrol*).—1, *Blechnum spicant*, the common hard Fern; 2, *Athyrium rheticum*, the erect Lady-Fern; 3, *Asplenium adnigrum*, the Black Spleenwort; 4, *Lastrea cristata*, the Crested Buckler-Fern; 5, *Cystopteris fragilis*, the Brittle Bladder-Fern. (*C. B. H.*).—Only seventeen specimens! and some of them leaves of Begonias. It is perfectly unreasonable to expect us to name more than three or four at a time. 1, *Cyrtotum lacinum*; 2, *Lastrea aristata*; 3, *Anemodictyon phyllitis*; 4, *Pteris geraniifolia*; 5, *Adiantum capillus-Veneris*; 6, *Blechnum brasiliense*. (*F. C.*).—Your plant is the *Veratrum nigrum*, a noble plant for the shrubby border. The Passion-Flower you mean is the *Passiflora curulea*, the most hardy, if not the very handsomest, of the genus. (*G. E.*).—1, Common *Phlox*, *Paula denticulata*; 2, Common *Centaur*, *Erythraea centaurium*; 3, Eyebright, *Euphrasia officinalis*. (*Eaton Cliff*).

—We do not undertake to name a plant from a leaf only. We believe yours to be from the Common Hydrangea; and the Geranium was too fallen to pieces to be judged. (*Old Subscriber, J. C.*).—*Hedychium Gardnerianum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FRESH GROUND FOR CHICKENS.

WE cannot help thinking much good might result and great information be derived if amateurs would be more communicative one to another through the columns of periodicals devoted to the objects in which they are interested. Many of the queries sent to us are evidently from competent and observing people, and afford ample evidence of the ability of the writers. Such, while they want information on one point, could evidently afford it on twenty. One has written to us on "Tainted Ground." Although he has four or five acres at his disposal, yet, for security's sake, he has reared his chickens for years in a small enclosed space. They did well for two or three years; but afterwards, although supplied with all they could require, the chickens languished, many died, and the survivors were sickly. He was not a man who would accept such a position without inquiring the cause, and was soon told by a gamekeeper the ground was tainted, consequently unfit for rearing chickens. The assertion was to be tested by the removal of a brood that was daily becoming less to the open space. They recovered directly. A change of ground is good for old birds; but it is necessary for chickens that are artificially kept. There is not on a lawn or small paddock the constant change of surface there is in a farmyard, nor is there the same process of natural chemistry in operation. Where Pheasants are bred in large numbers, it is a common thing to be obliged to relinquish ground possessing every advantage, because it is tainted. Birds will not grow up—they cannot be reared upon it. The old birds are not affected by it; but even in them, as in the human being, change of air and scene are beneficial. It is impossible to say in what this taint consists. Analysis has failed, so has dissection. Wherever it can be done, prudence would, therefore, dictate that the spot where chickens will be put with the hens under the rips should be as much as possible kept quite free from poultry till it is required for the purpose. We have no doubt many of the complaints we receive of inexplicable deaths from no apparent cause, and spite of every precaution, provision, and provision, may be attributed to this cause. Meeting the subject may, perhaps, turn the attention of competent people to it.

MANCHESTER AND LIVERPOOL POULTRY EXHIBITION.

THE Manchester and Liverpool Agricultural Society held its first meeting in the year 1847. It was then constituted by the amalgamation of the Manchester Society, whose first meeting dates back so far as 1767, with the Liverpool Society, formed in 1830. With, therefore, an undivided interest, and embracing so populous a district as that in which its annual meetings now take place, the natural result has been progressive improvement; and it is patent to every one that any feature that might by its utility and popularity add to its advancement in public favour, has invariably received the ready and earnest attention of its controllers. This Society enjoys also the untiring help of one of the most indefatigable of secretaries, Mr. Ryder,

whose energies are thus annually severely taxed in connection with this Meeting. Courteous to every one, and with ready advice to any exhibitor requiring it, it is only fair thus to admit the Manchester and Liverpool Meeting is in no slight degree indebted to this gentleman's personal exertions for its present high position.

To give a slight idea of the gigantic proportions of this year's meeting we at once consult the printed catalogue. In it we find registered no less than 3141 entries, entailing an amount of labour in its management none others than the actually experienced could imagine. This total of entries, of course, included horned cattle, horses, sheep, pigs, implements and machinery, grain, roots, cheese, butter, fruits, flowers, and last, though not least, dogs and poultry. So vast a display as that of this year, and one so well calculated to amuse and instruct the public eye, has rarely been exhibited at a single meeting.

The carrying-out of the general arrangements was entrusted to the Messrs. Jennison, of Belle Vue Gardens, near Manchester; and although compelled to do battle with most unpropitious weather, these gentlemen eventually brought all to a favourable conclusion. The day and night also previous to the Show being opened was one continuous heavy rain, nor at the break of day was there any symptom whatever of abatement. About seven or eight o'clock, however, and this only just as the Arbitrators were about to commence their duties, the sky suddenly cleared, the sun broke brightly, and every face beamed with congratulation at a result all had deemed, till now, an utterly hopeless one. But expressly to the poultry.

This department contained considerably beyond 200 pens, and as a whole, the collection was unquestionably a good one. It is true many classes were damaged in appearance (particularly to the inexperienced eye), by the bulk of the specimens being then in full moult; but as at this season it is useless to expect anything different (because naturally so), the few remarks we purpose offering our readers will not bear particularly on this shortcoming.

The Black *Spanish* class was a strong one, the well-known breeder Mr. Rodbard, of Aldwick Court taking both first and second positions. The quality of the faces of this gentleman's chickens was quite beyond exception; but we cannot help noticing that these birds were of a very diminutive size when compared with many shown from the same yards during past years. The same amount of character, combined with a larger size, would be a decided improvement. In Grey *Dorkings* Captain Hornby was pre-eminent, all his specimens being quite above the remaining competition—in short, they were all exceedingly well-built large early chickens, and matched most effectively. The moult of the *Game* fowls told seriously against them, but here again Captain Hornby stood well. Mr. Julian, of Beverley showed also some very worthy birds of these varieties. In *Cochins* the muster represented many of the first things of this year from our most noted amateurs. Our attention was particularly directed to a feature, that though somewhat general in the Buff *Cochin* class, by no means justifies the practice—viz., the exhibition of Silver Cinnamon pullets with a Buff cockerel. Another very fatal objection ruled rather heavily against the interests of several exhibitors. It arose from dropping and waved combs in one or more pullets, though otherwise unexceptionable. From these shortcomings the *Cochin* classes, though "very taking at first sight," would ill bear to be closely scrutinised. The *Hamburghs* were a very strong feature of the Show; and the *Polands* though few in numbers were decidedly good. Harvey Dutton Bayly, Esq., stood far above competition in the *Bantam* classes. It was as complete a "walk over" as we could imagine.

In *Aylesbury Ducks*, Mrs. Seamons stood as completely beyond the reach of rivals, even a single glance of the Judges determining all the three prizes in her favour. In *Rouen Ducks* faulty bills were sadly prevalent, though the class was most extensive. It is well worthy of remark that a faulty Duck of this breed as to her bill, nearly without exception, perpetuates the failing in every duckling. To breed from such is the certain forerunner of disappointment; and as a selection may be made at a very early age, to hand over to the cook at once such ducklings as are evidently not fit for exhibition would prevent much unnecessary

outlay, besides providing for the table at a time when their appearance thereon would be decidedly far the most acceptable.

The *Turkeys* and *Geese* were as good as we have seen this season. The rage for exhibiting two, or even three ganders together instead of a male and two females seems, however, to extend itself.

Decision on the part of our poultry Judges must be here called into action, or sales of these really useful birds will fall sadly below what has been the usual demand. We know several agriculturists whose hopes have been thus frustrated, and their tempers not a little soured into the bargain, by having eventually to roast a large proportion, and perhaps all of a pen of so-called *Geese* thus "claimed" at high prices.

DORKINGS.—First and Second, Capt. W. Hornby, Prescott. Third, J. Robinson, Garstang.

SPANISH.—First and Second, J. R. Rodhard, Warrington. Third, W. Woolley, Farnbury.

GAME COCK.—First, H. M. Julian, Beverley. Second, J. Fodden, New Ferry. Third, C. W. Brierley, Rochdale.

GAME (Black-breasted Red).—First, H. M. Julian, Beverley. Second, Capt. W. Hornby, Prescott. Third, W. Gamon, Chester.

GAME (Brown-breasted Red).—First, Capt. W. Hornby, Prescott. Second and Third, J. Wood, Wigan.

GAME (Any variety).—First and Second, J. Holme (Duckwing). Third, C. P. Ackers, Wigan (Duckwing).

COCHIN-CHINA (Buff or Cinnamon).—First and Third, T. Stretch, Ormskirk. Second, G. Fell, Warrington. Highly Commended, G. Fell. Commended, E. Musgrove, Ormskirk.

COCHIN-CHINA (Grouse and Partridge).—First, T. Stretch, Ormskirk. Second, E. Tudman, Salop. Third, Capt. Heaton, Manchester. Commended, T. Stretch.

HAMBURGHS (Golden-pencilled).—First, Messrs. Carter & Valiant, Poulton-le-Fylde. Second, J. Dixon, Bradford. Third prize withheld.

HAMBURGHS (Silver-pencilled).—First, H. Pickles, jun. Skipton. Second, J. Dixon, Bradford. Third, J. Platt, Bolton. Highly Commended, S. Fielding, Middleton.

HAMBURGHS (Golden-spangled).—First, J. Dixon, Bradford. Second, S. H. Hyde, Ashton-under-Lyne. Third, J. Roe, Manchester.

HAMBURGHS (Silver-spangled).—First, J. Robinson, Garstang. Second, J. Dixon, Bradford. Third, T. Rigby, Winsford.

POLANDS.—First and Second, J. Dixon, Bradford. Third, P. Unsworth, Warrington.

BANTAMS (Game).—First, T. H. D. Bayley, Biggleswade. Second, J. W. Morris, Rochdale. Third, J. Dixon, Bradford. Commended, W. Lawrenson, Poulton-le-Fylde.

BANTAMS (Any other variety).—First and Second, T. H. D. Bayley, Biggleswade. (By some mistake both this gentleman's pens of Sebrights were exhibited in one pen. The Silver-laced stood first, and the Gold-laced second.) Third, J. Dixon, Bradford.

ANY OTHER BREED.—First, J. Dixon, Bradford (Black *Hamburghs*). Second, W. Dawson, Hopton (White *Cochin-China*). Third, Mrs. M. Seamons, Aylesbury (Brahma *Pootra*). Highly Commended, H. B. Lee, Bewdley (Brahma *Pootra*); J. Robinson, Garstang (White *Dorkings*).

GOSLINGS.—First and Second, D. R. Davies, Knutsford (White and Grey). Third, T. Burgess, Whitchurch (White).

DUCKLINGS (Aylesbury).—First, Second, and Third, Mrs. M. Seamons, Aylesbury.

DUCKLINGS (Rouen).—First, J. Holme, Knowsley. Second and Third, W. Gamon, Chester.

DUCKS (Any other breed).—First, F. W. Earle, Prescott (Black *East-Indian*). Second, J. Dixon, Bradford (Grey *Call*). Third, C. P. Ackers, Wigan (Wild). Highly Commended, J. R. Jessop, Hull (Black *East Indian*).

TURKEYS.—First, Capt. W. Hornby, Prescott. Second, J. Dixon, Bradford. Third, J. Ellis, Hale Bank.

EXTRA STOCK.—Commended, Mrs. G. H. Cook, Hartford Hall, Cheshire.

Mr. John Douglas, of The Cottage, Ellenhall, near Eccles-hall; and Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham, were the Judges.

KEIGHLEY POULTRY EXHIBITION.

TWENTY-ONE years have now passed away since the first agricultural Show was held at Keighley, and for about the half of that period the addition of poultry has led to a great increase of its attractions. It is a gratifying result for us to announce that the meeting of last week not only showed a large increase in the number of entries over those of previous years, but a still more important feature was that the poultry competing was as good as can be met with at the largest of such exhibitions. Although the weather for the last few days proved most precarious and unpromising, most luckily the day on which the Show was actually held proved quite a fine one, and by this happy coincidence a company far beyond precedent assembled at Keighley. That the Committee really work hard to insure success must be obvious, even at first glance, among those who attended last week, and this has always been so. Their just reward is pretty well expressed by the somewhat quaint inscription that met the eye among some of the first on

leaving the railway station, "Perseverance wins the day." Similar banners, expressive of a varied host of sentiment, evidently the first impulses of their respective owners, we had almost said, filled up the streets from the station to the show-yard, combined with such quantities of evergreens and paper flowers as to be really astounding, nearly every spare yard of space being thus temporarily dressed out. A volunteer rifle band proved a really good help to carry out the festivities of the day. As the clock struck the hour of six the church bells rang merry peals, and very quickly the din of transit to the show-yard, the morning sun brightly shining on the passers-by, proved there would certainly be no lack of either cattle, implements, or poultry, and that the much-desired fine day appeared certain. Things progressed in this orderly and general manner until between ten and eleven, when, the band being summoned, the Committee and Judges walked down to the Exhibition, the band playing right lustily all the distance. This plan drew together a multitude of visitors, and on their arrival all who chose to give the higher rate of entry were at once admitted. Open judging, as it is sometimes called, was therefore the only course that could be pursued in the immediate presence of owners, the most anxious as being the most interested. Our own opinion, that Judges should in all cases conclude their arbitrations before the public are present, is well known; and very little extra trouble is by this plan entailed. It is quite worthy the attention of those societies which have not as yet adopted it. The poultry were arranged, as on all previous Shows, in one single tier in the open field; and, on first entering, so capital a collection proved very imposing.

Cochin-China fowls of any feather formed the two first classes. In the adults Captain Heaton's well-known Partridge-coloured pen, and in the chickens their capital Buff ones readily walked away from all competition; in fact, the Captain secured both at first glance. For the second prizes in these classes a good struggle ensued. It must be well remembered *Cochin* fowls must never be shown with irregular combs, a general defect throughout the whole of these classes at Keighley save the winners of the two highest premiums. The *Spanish* were good, but not exhibited in good feather.

We now come to the best classes we have seen for many years past, the five varieties of *Hamburghs*, for of Black ones, for which prizes were duly allotted, no less a number than seventeen pens were entered. These latter were all so good that truly it appears the Black *Hamburghs* now well deserve a class to themselves. These fowls are really a useful description of poultry, they are very far harder than most breeds, lay large-sized eggs and that frequently, and are unquestionably in good place as table fowls. In *Silver-pencilled* and *Silver-spangled Hamburghs* the classes were pre-eminently good. All the best known breeders of *Hamburghs* having entered the lists, it ceases to be a wonder that the greatest amount of anxiety was manifested as to the results, and a reference to the annexed prize list will prove that none of these prizes were of easy attainment.

The *Grey Dorkings* were, without doubt, the superior class through; but we much regretted to find a well-known exhibitor showing a cock so rumpy that it was equally offensive to the eye as the nostrils, even at some yards distance from the pen. This bird should by all means have been returned to its owner without any delay whatever, but some circumstance or other prevented it. It was the worst case of rump that has been seen at any show for years past. To send birds thus afflicted is absolutely an injustice to others, as this complaint is most infectious.

The *Game* were not equal to expectations, and fell far short of holding their particular classes with the credit due to the Show generally.

In *Geese*, *Ducks*, and *Pigeons* Keighley Show stood most creditably.

The extra class for new varieties of fowls was also well filled. In this class a sad ill-luck attended the exhibition of one pen of first-rate *White Polands*, which, of late, are becoming a far greater rarity than in years back. The cockerel, as soon as it was penned, flew up against the top, and fell so prostrate as never to be able to stand afterwards from concussion of the brain. Although so materially injured, the quality of this pen was so good as to elicit a high commendation. Though not probable, we trust its recovery is

not impossible. The *Poland* exhibitors, with Mr. Dixon, of Bradford, at their head, showed the most creditable collection seen for a long time back of every known variety. These added very much to the credit of the Keighley Show, for, when good, they invariably gain the best attention of the public eye from their combined beauty and singularity.

COCHIN-CHINA.—First, Capt. Heaton, Lower Broughton. Second, J. Firth, Halifax. Highly Commended, J. G. Sugden, Eastwood House. *Chickens*.—First, Capt. Heaton. Second, E. Smith, Middleton. Highly Commended, S. Shaw, Stainland; M. Mahoney, Gilt Stock, Bingley.

SPANISH.—First, E. Beldon, Gilstead. Second, J. Dixon, Bradford.

CHICKENS.—First, S. Robson, Brotherton. Second, J. Siddle, Halifax. Commended, E. Beldon.

CHITTERPAT.—First and Second, E. Beldon, Gilstead. Commended, J. Dixon, Bradford; A. Houghton, Micklethwaite. *Chickens*.—First and Second, J. Dixon. Highly Commended, T. C. Midgley; E. Hutton, Pudsey. Commended, W. Bairstow, Bingley; S. Shaw, Stainland.

PRESANT (Golden).—First, E. Beldon, Gilstead. Second, J. Newton, Sisco. Highly Commended, J. Dixon, Bradford. *Chickens*.—First, J. Ellis, Kirkgate, Leeds. Second, J. G. Sugden, Eastwood House. Highly Commended, J. Dixon; R. Naylor, Braithwaite; A. Brag, Holmfirth. Commended, E. Beldon.

HAMBURGH (Golden-pencilled).—First, S. Smith, Northwram. Second, J. Dixon, Bradford. Highly Commended, E. Beldon. *Chickens*.—First, E. Beldon. Second, S. Smith. Highly Commended, S. Shaw, Stainland; R. Hemingway, Shelf. Commended, J. Dixon; J. Binns, Keighley; F. Taylor, Laycock.

PRESANT (Silver).—First, E. Beldon, Gilstead. Second, J. Dixon, Bradford. Highly Commended, E. Beldon; J. Thompson, Sil-den. *Chickens*.—First, A. Brag, Holmfirth. Second, J. Fielding, New Chnrch. Highly Commended, W. Smith, Kildwick; E. Beldon; J. Dixon; S. Shaw, Stainland. Commended, T. Hanson, Thwaites; W. Bastow, Bingley; J. Richmond, Langley; W. Sagar, Saltaire.

PRESANT (Black).—First, E. Beldon, Gilstead. Second, J. Dixon, Bradford. *Chickens*.—First, J. Dixon. Second, S. Shaw, Stainland. Highly Commended, E. Hutton, Pudsey. Commended, J. Dixon; J. Tempest, Haworth; E. Beldon; J. Smith.

POLAND PRESANT (Gold or Silver).—First and Second, J. Dixon, Bradford. Highly Commended, E. Beldon, Gilstead. *Chickens*.—First, W. Newsholme, Bingley. Second, J. Dixon. Highly Commended, J. Dixon.

DORKING.—First, E. Smith, Abdduton. Second, J. Dixon, Bradford. *Chickens*.—First, T. E. Kell, Wetherby. Second, F. Key, Beverley. Highly Commended, E. Leach, Rochdale; W. Newsholme, Bingley. Commended, G. Greaves, Pool.

GAME (Red).—First, J. Firth, Halifax. Second, W. Bentley, Scholes, Cleckheaton. Commended, J. Sunderland, jnn., Coley Hall. *Chickens*.—First, H. Snowden, Great Horton. Second, E. Beldon, Gilstead. Highly Commended, R. Hemingway, Shelf. Commended, T. Dyson, Halifax; T. Spencer, Haworth; J. Firth, Halifax.

GAME (Any other variety).—First, E. Beldon, Gilstead. Second, J. Sunderland, jnn., Coley Hall. *Chickens*.—First, J. Firth, Halifax. Second, J. Hanson, Shelf.

GAME (Black or White).—First, J. G. Sugden, Eastwood House. Second, E. Beldon, Gilstead. Commended, J. Dixon, Bradford; S. Schofield, Heckmondwike. *Chickens*.—First, S. Schofield. Second, J. Dixon. Highly Commended, E. Hutton, Pudsey. Commended, E. Hutton.

ANY DISTINCT BREED.—First, J. Smith, Keighley (Black *Polands*). Second, J. Dixon, Bradford (Malays). Highly Commended, E. Beldon, Gilstead (Black *Polands*). Commended, J. Dixon (Black *Polands*). *Chickens*.—First, J. Smith (Black *Polands*). Second, E. Leach, Rochdale (Dark *Brahmas*). Highly Commended, J. Shackleton, Laycock (White *Polands*); J. Dixon (Black *Polands*). Commended, J. Pares, Childown Hall (Brahmas).

DUCKS (Rouen).—First, S. Shaw, Stainland. Second, J. Dixon, Bradford. Commended, S. Shaw; E. Leach, Rochdale.

DUCKS (Austrian).—First, E. Leach, Rochdale. Second, F. M. Hindle. *DUCKS (Black Indian)*.—First and Second, J. Dixon, Bradford. Highly Commended, S. Shaw, Stainland. *Ducklings*.—First, S. Shaw. Second, T. E. Kell, Wetherby. Commended, J. G. Sugden, Eastwood House; J. Dixon; T. Spencer, Haworth.

GESE.—First, J. Dixon, Bradford. Second, T. Brigg, Guard House.

TURKEYS.—Second, J. Dixon, Bradford. First, Withheld.

MR. MANOR FROD'S PRIZE.—Silver Cup, J. Dixon, Bradford. Highly Commended, J. Fielding, Manche-ter; S. Shaw, Stainland.

PIGEONS.—*Pouters or Croppers*.—First, S. Robson, Brotherton. Second, E. Beldon, Gilstead. *Hens*.—First, S. Robson. Second, S. Shaw, Stainland.

CARRIERS.—First, W. Smith, Skipton. Second, S. Shaw. Highly Commended, E. Beldon; S. Robson. *Hens*.—First, E. Beldon. Second, J. Thompson, Bingley. Highly Commended, S. Shaw. *Almond Tamblers*.—First, E. Beldon. Second, S. Shaw. *Balds, Beards, or Mottled Tamblers*.—First and Second, S. Shaw. *Orls*.—First and Second, E. Beldon. Highly Commended, H. Shuttleworth, Skipton. *Turbits*.—First and Second, S. Shaw. *Jacobins*.—First and Second, S. Shaw. *Fantails*.—First and Second, E. Beldon. *Turbs*.—First, S. Shaw. Second, E. Beldon. Highly Commended, W. Smith, Skipton. *Dragons*.—First and Second, J. Wadsworth, Halifax. Highly Commended, J. Laycock, Keighley; J. Thompson, Thimpton. First, E. Beldon. Second, S. Robson. Commended, S. Shaw, Leeds. *Maggies*.—First and Second, S. Shaw. Commended, J. Wade, Leeds. *Archangels*.—First, S. Shaw. Second, J. Thompson. Highly Commended, J. Thompson. *Any other breed*.—First, E. Beldon (Nuns). Second, S. Shaw (Spots). Highly Commended, J. Thompson (Swallows); S. Shaw (Swallows); J. Wade (Silver Runt).

RABBIT.—*Long-Eared*.—Prize, J. Sunderland, jnn., Coley Hall. *Any other kind*.—First, C. Hodgson, Keighley. Second, J. Reedy, Keighley.

The Arbitrators for poultry were Mr. Edward Hewitt, of Sparkbrook, near Birmingham; and Mr. Thompson, of Bradford, Yorkshire.

CRYSTAL PALACE POULTRY SHOW.—By the time this paper is in the hands of our readers it will want but one month to the

Crystal Palace Show. It is time the entries were made. We hope amateurs from all parts of England will support this our London Show, and that the Exhibition will be worthy of the locality. It must be borne in mind this is instead of the winter Show. The time is altered to insure finer weather and longer days than in December; also to allow birds to be shown both at Birmingham and this place without injury to themselves or inconvenience to their owners.

THE SQUIRREL.

THIS pretty little animal is classed by naturalists among the Rodentia, or gnawing animals, on account of its teeth; the front ones being formed, like those of the rabbit or rat, for cutting or gnawing, while the hinder ones are adapted for grinding. In a wild state Squirrels feed on nuts, acorns, beechmast, and the seeds of coniferous and other trees. Thus autumn and early winter are their times of plenty, and it is a question on what they feed when their favourite food becomes scarce, as it must do in spring. Probably they eke out their scanty store with bark, buds, and tender shoots until the birds begin to lay, when a plentiful repast is offered to them in the form of eggs and young birds, of which, no doubt, they destroy a great many.

The Squirrel's nest, or more correctly the dray, is a rather large structure composed of moss, &c., and not unfrequently having for its foundation the old nest of a Wood Pigeon or some other bird: it is domed over and has two openings. I believe they usually have two young at a birth, which, when tolerably grown, may be taken and reared by hand, when they become very tame and amusing pets. The best plan I know of is to suckle them on new milk by means of a phial, with a duck or other small quill put through the cork for them to suck through. The phial of milk may stand in a basin of hot water till the milk is blood warm. Great care must be taken that they have no sour milk, and that they are kept warm, particularly at night, or they will not thrive.

The best cages I know of are those usually made with the centre like a large wheel that revolves, and having a compartment at each end, the one to be filled with moss or soft hay for the dormitory; the other provided with a pan for bread and milk, and to be used as a feeding-room and for other necessary purposes. It should be provided with a sliding bottom, to be sanded or covered with some absorbent substance so as to be easily cleaned. Some persons object to these revolving cages as suggestive of the treadmill; but in reality they afford the confined Squirrel an unbounded field for exercise, which to such a naturally active animal must be very conducive to health. I know of no other form of cage that could give the same amount of exercise in one continued and uninterrupted burst. The only objection I can see to the revolving-wheel cage is where two Squirrels are kept together, that one attempting to pass while the other is spinning the wheel it is liable to be hurt; but for one Squirrel I consider this the best form. Such cages are commonly to be purchased at most of the London cage-makers or in almost all large towns; the price I do not know.

The food I would advise for a Squirrel in confinement should be a little sopped bread and milk, corn, and nuts; but if any one having greater experience in keeping Squirrels can advise a more wholesome diet I hope he will do so.

I find pet Squirrels are very tender, and usually come to an untimely end—I mean such as are brought up tame, and consequently are often indulged with a run about the rooms. Their active habits prompt them to climb almost everything and everywhere, while smooth-planed doors, polished furniture, and curtain-poles do not offer the secure footing which the rough bark of trees does, and consequently the pet Squirrel in his gambols often meets with a fatal fall, to the great grief of an admiring circle of friends.—B. P. BRENT.

FRAME-HIVES.

I SHOULD like to trespass on your space and ask your esteemed correspondent, "B. & W.," a question or two.

I intend to adopt in my apiary either Mr. Woodbury's frame-hives, or his thirteen-inch bar-boxes; I can hardly

make up my mind which. I want a frame-hive, but my bee-house and hive-covers are too small for the 14½-inch hive, and I want to retain them, as otherwise they answer very well.

"B. & W." says the single advantage of frames is the facility they afford for moving the combs without crushing a single bee, and the ease with which operations can be performed. I would ask him what he thinks about a plan I am almost determined to adopt to suit my case, and that is to fasten pieces of perforated zinc three-quarters of an inch wide, and long enough to reach to the bottom of the hive, to the ends of my bars, and so adjust them as to hang a quarter of an inch from the sides of the hive, affording the bees space to pass between them and the hive. This would prevent the combs being attached to the hive itself, and would give me, unless I misjudge, the "single advantage" of frames, with the advantage of a hive taking less room than when a full frame is used. With this half-frame, if I may call it, I would use thirteen-inch square hives, which happens to be the extreme size I can conveniently adopt.

Or would "B. & W." object to the adoption of thirteen-inch square hives 10 inches deep as an alternative with the above, with full frames?

Will Mr. Woodbury, or "B. & W.," say if they would ever resort to driving bar or frame-hives? If they would drive them, could it be effected by removing the crown-board and driving upwards?—A. B. C.

[I cannot imagine any circumstances under which it would become necessary to drive bees in a frame-hive; but I doubt not that they could be driven upwards. "A. B. C." had better enlarge his thirteen-inch boxes by deepening them to 11 inches inside, and use complete frames rather than resort to the contrivance he has described.—A DEVONSHIRE BEE-KEEPER.]

INTRODUCING SEALED COMB INTO A STRANGE HIVE—COMB FALLING.

CAN you tell me where to procure a Ligurian queen bee? We are told in books after driving a hive, if brood is in the combs and you give them immediately to another hive, they will hatch it out and thereby strengthen a hive. My first experiment in driving a hive succeeded in less than ten minutes. I found the driven hive with beautiful new clean comb partly filled with sealed brood, which I instantly placed on the top of a box-hive under a bell-glass, which I covered with a straw hive. Next morning, instead of hatching, the bees were working busily at removing all the brood. I left the comb for several hours, and then, thinking the bees were only wasting their time, I removed it and examined the brood, and it appeared perfectly healthy in different stages, but only one bee hatched whilst I was looking at it after placing it under the bell-glass.

Can you also remove another difficulty? Last year I bought a Woodbury bar-hive, and wishing to take out two bars of honey in the beginning of this month, I found I had first to cut away the comb from each side of the hive where it was attached and then the weight of the honey broke it away from the bar, so the only way was to lift the hive and let the comb drop through on to a dish.

I have had frames made to put in instead of merely the bars, and how am I to proceed with the remainder of the bars? as next year I am looking forward to experiments in making some artificial swarms, having mastered driving and uniting; but if the combs all break off the bars what am I to do?—A LADY BEE-KEEPER.

[Mr. Woodbury having ceased to send out queens and confined his attention to the multiplication of Ligurian stocks, we do not know where the former are to be procured. Bees will usually hatch out sealed brood under the circumstances you describe. If you had attached the combs to bars and placed them in an inhabited hive, they would certainly have done so. The accident of a heavy side-comb falling from its bar might have happened to any one, but a novice would be especially liable to it. By carefully severing the side attachments, and a little more skill in manipulation, you may avoid it in future. A Woodbury bar-hive is too small for the reception of frames. It should have been enlarged to 14½ inches inside from front to back, and would then take nine frames of the usual size.]

PARTHENOGENESIS—BEE SUPERSTITIONS.

THANKS to our chief for his reply respecting the age of a queen. Let all writers on the subject of bees and bee-keeping refrain from giving "pokes in the side," and, doubtless, amongst us we shall arrive the sooner at the true history and nature of the honey bee. If the history of the honey bee, as given by one of the Hunters (surgeons), in his medical works were published piecemeal during the winter months it might prove acceptable to the fraternity. I think his account of their habits is as near the truth as any I ever read.

I do not myself quite accept parthenogenesis as a fact, neither do I believe in the great longevity of the queen. If "I am slow to believe," I trust all the brethren will forgive me that wrong, and honour him the more who in convincing me proves the truth we are all aiming to know. I was not surprised at the announcement of the two queens at one time at large in a hive, I had long suspected it might be so. When a hive is in a flourishing condition, the inmates work, I have little doubt, by certain rules. Adverse seasons, accidents by flood and field disarrange the system, and hence bee-masters are led to jump at false conclusions. I imagine queen bees are turned off from the hive when they are useless, just as drones and neuters are. What becomes of them I have not the least idea. Sometimes you may find a young queen bee dead before a hive, sometimes a few drones and workers, but not always. I had a hive this year fuller of drones than usual (owing to my having given them too much drone-comb), not one of the many thousands in it are now to be accounted of. If they drop in their flight away from the hives, why do we not meet with them in their travels, falling on our aristocratic noses as we turn them up to the skies? My parish is full of hives from one end to the other, and I never stumble upon a dead bee of any sex, unless it be a few within a few yards of an apiary. Still confessedly they vanish, and that speedily too. For a short time, therefore, I think it probable an old worn-out queen and the princess regent may exist and be found in a hive; but experience says not for long. The old queen will go where her subjects, and "the good niggers in due time go." Perhaps to fairy land, or Jonas Jackson may tell us where. By-the-way, it is a shame to laugh and joke too much, even at the surmises of Jonas Jackson. I can tell him for his comfort, that I once lived in a village where every bee-master was more or less imbued with the superstition attendant the death to bees when their owners have died. Need I say I combated the opinion on every occasion as in duty bound? Nay, I even accepted a hive in the winter (heavy and full of bees), belonging to a lord just dead in order to prove the fallacy of the superstition. I made it known all round my parish and asked all the bee-masters to witness the result, and my mouth was shut for ever after—for, alas! the hive did no more good and died in the spring. I am not superstitious, believe me, but I have known other instances and been told of many more where similar results have followed.

With reference to honeydew or falls, I once had a hive in Yorkshire whose inhabitants gathered and stored honey on or about the 10th August, when my other hives had gone to the moors. I lived in Yorkshire as a bee-master upwards of fifteen years, and I never knew of honey gathered, except on the moors, after the second week in July. That honey was dark, and I found bees working on the oak leaves at the time. The gathering lasted about three days. I was told that previous to my living in the village a similar case had happened, when a hive left at home did more good than others sent to the moors.

If the "DEVONSHIRE BEE-KEEPER" will observe for the future, he will find the truth of my surmise, that it is no use (at least late in the summer), to return bees from a removed super. They would have no place in the hive, no work to do, their occupation would be gone, and the cry would speedily arise, "Away with them!" They would not be killed like robbers from another hive, but they would be driven off as useless.—A HAMPSHIRE BEE-KEEPER.

[If "A HAMPSHIRE BEE-KEEPER" will refer to my articles in Nos. 25 and 30 of THE JOURNAL OF HORTICULTURE, he will see the evidence upon which parthenogenesis rests. It really amounts to absolute demonstration, and it appears to me perfectly impossible to produce stronger evidence of any fact whatever.

The practice of turning hives completely round when a corpse is carried out of the house is even now by no means obsolete in this county. I know an instance in which it was resorted to no longer ago than last winter; but, to the astonishment of the natives, even this operation did not prevent the bees dying of starvation in the absence of more substantial assistance after a very bad honey season. A friend of mine relates a laughable story of a hearse and mourning-coaches starting off at a terrific pace and leaving the astonished bearers with a heavy coffin on their shoulders and no hearse to deposit it in, owing to the bees not comprehending the necessity of this forced revolution, and resenting it by an attack on the unoffending horses.—A DEVONSHIRE BEE-KEEPER.]

OUR LETTER BOX.

CROSS-BRED FOWL (*Notice*).—The birds you mention as cross-bred can be shown in the class for "Any other new or distinct variety." It is especially intended for those that have no other place—i.e., that belong to none of those breeds not which separate prizes are offered. You can call them by any name you please; or you can describe the process by which they were produced.

DUBBING A BANTAM GANE COCK (*Idem*).—It should not be dubbed before it is six months old, and if it is older so much the better. If dubbed when younger the comb grows again, and necessitates a second operation. It should not be done while the bird is changing plumage, and it must not be done in frosty weather.

PULLETS LAYING (*Idem*).—The pullets began to lay because they were seven months old. The breed may have something to do with their now sitting. They will lay as well without a cock as with one, and they will become broody. But, of course, the eggs are clear.

DISTINGUISHING THE SEX IN YOUNG GESE (*Farmer's Wife*).—It is very difficult to distinguish between Goose and Gander, especially when they are young. Among many other methods, it is said that if the birds be put in a pen or any enclosed space and a door be thrown in, the Geese will all withdraw, while the Gander extends his neck and pokes. Another is, that the sack or bag that hangs down between the legs of both sexes is double in the male, and single in the female. Again it is said the neck of a Gander is shorter and thicker than that of the Goose. If that be all put together a proper judgment may be sometimes arrived at, but not always. Close observations and examination are the only certain guides.

CHICKENS DYING SUDDENLY (*Lock*).—Be some means or other your chickens get at something that is poisonous. One or two might do it, and it might be attributed to giddiness; but as that is not contagious, and as the disease seems to be the rule with your chickens, you must seek the cause in their diet.

FLOOR OF HEN-HOUSE (*Young Begonia*).—Cover the floor of your house with gravel, as well as your yard. Ashes are sharp and prickly to the feet of chickens, especially of heavy ones, and they can only walk on them with pain and often injury. This would make them disordered for exertion, and the complaint you make might arise from the constant use of one or the other of the legs while the other rested.

PRIZES AT THE SHEFFIELD POULTRY SHOW.—I have been informed that some of the local exhibitors at the late Sheffield show have had the prize money paid them. Can any of your readers say if this be true?—C. S.

TIGONS AT POCKINGTON.—(*Exhibitor*).—We cannot insert such a communication. General charges, and unsigned by the complainant's real name and address, are inadmissible.

POINTS IN PARTRIDGE COCHIN-CHINA PULLETS AND COCKRELS.—(*J. C.*) Light breasts and bodies are great faults in Grouse or Partridge Cochins, and fatal faults in competition. In these, as in all others, the combs should be straight. The cock should have a perfectly black breast; hackles and saddle, deep orange, with black stripe down each feather; black thighs and red wings. The hens should be grouse coloured all over, with as little yellow tinge as possible. Both should have yellow legs, well feathered.

BASKETS FOR GLESE AND TURKEYS.—(*J. G.*)—Open baskets are the lightest; but they are liable to the very serious objection that the tenants are then subject to the attacks of any one. Many a bird has arrived at a show tailless, because he was sent in an open basket. Our belief is that, for a short journey of from two to four days, a round stout wicker-basket, covered with sack or strong cloth, is all that is required. It should be fastened round, with the exception of about one foot, which should have temporary ties that may be undone for the purpose of feeding on the road. They should be high enough to allow the birds to stand up.

BEGINNING BEE-KEEPING (*A Notice*).—You may remove your hive at once, but it should be done carefully so as to avoid injury to the combs, which ought to be heavy at this season. Tie it up in a coarse cloth of open texture (cheese-cloth), and have it carried steadily by hand. You may cover the old straw hive with a neat case, but do not attempt to transfer the bees to another hive. Buy "Bee-keeping for the Many," which will give you the information you require.

LONDON MARKETS.—SEPTEMBER 14.

POULTRY.

We have little change to note. There is a good but not a large supply of Partridges. Grouse remains scarce. There is little or no demand for poultry.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 65.7°, and its night temperature 44.5°. The greatest heat was 82°, on the 25th, 1832; and the lowest cold, 26°, on the 26th, 1855. The greatest fall of rain was 1.68 inch.

HARDY AQUATICS.

ATER, when well displayed, is always acceptable in scenery of any kind, but more especially in ornamental gardening, and rock-work is generally considered to belong to it. Rock-work, however, in my estimation is no ornament to

water, for in nature rocks do not generally accompany inland waters. Though they often do so in mountain torrents, yet in lakes near them the ground partakes more of the character of a bog than of high ground where we generally look for rocks, and it cannot be denied that Nature is the best teacher, yet the aim of the gardener is mostly directed to bringing as large an amount of interest and beauty into as small a compass as possible. He cannot produce a natural effect in the compass of a few yards, but he may so diversify his subject as to bring a large amount of beauty into a limited compass, and if the area were extended, a natural effect, or an effective picture would be produced.

Now, my aim being to deal practically with the question, I will endeavour to treat of water under the forms in which it presents itself in gardens, and in giving a few hints, hope to benefit those in possession of streams, lakes, or pools of water, already in, or passing through their grounds. "But I have no water in my ground," I hear some one say, "and I like aquatics." For your benefit I will introduce a chapter on making and fitting up a basin or pool for the growth of aquatics.

The selection of a suitable position is the first step towards forming an aquarium, and that depends on the supply of water quite as much as on surrounding objects. Economy must govern us in selecting and carrying out the plan when the water is conveyed in pipes.

Any place not shaded from the sun will do for aquatics, though it is better if situated in a hollow, for then the expense of digging is less, and the designer may be enabled to throw up some rockwork over which the water can trickle in feeding the reservoir, or if the fall is great he may indulge in a fountain. Of course, any person can have a basin with a fountain in it, a pond accompanied by rockwork, or simply a pool according to his taste. It is not necessary even to have shade where there is rockwork, for there are numerous shrubs and alpine plants that are adapted for sunny situations; but when such plants as Ferns are desired, a certain amount of shade is required, which if placed so as to obscure the water will be detrimental to the growth of the aquatics. Aquatics require an unclouded sky, therefore shade is a disadvantage. The plants may grow in shade, but it is need-

less planting them under the shade of trees, and expecting them to flower. The situation, therefore, should be open; and as surrounding objects will in a great measure determine the manner in which that situation should be furnished or finished, I cannot do better than proceed with directions for forming an aquarium for the growth of plants.

If the aquarium is to be situated in the centre of a flower garden it should have a formal outline, and be large or small in proportion to the design. Little rockwork should be introduced in such a place, and if at all it should be low, and not wider than one-quarter the width of the water, extending all round; or if openings are left they should harmonise with the design of the beds, and be planted with plants of trailing habit that flower at the same time as those in the beds, with which their colours should harmonise. If a fountain be introduced it should be ornamental in design, and low, so as not to break the arrangement of the design. I consider a border of stone more ornamental than rockwork round an aquarium in such a situation, for then the plants can be better attended, and their peculiarities examined. In either case a walk of gravel one-fourth the width of the water should be made round it, unless the design be on grass, when a walk would be superfluous.

If the water is to be accompanied by rockwork the latter should be placed on the north side, the earth that comes out of the hole in forming the aquarium being raised into a mound there; or if it be desired to have a walk to the water on that side the earth may be piled up in two heaps, placing stones by the side of the proposed path to keep the soil up, and making the path narrow where it abuts on the water, and from that point abruptly widening outwards. If the walls of the path be 6 feet high adjoining the water, and the trunks of trees remarkable for their peculiar shapes be thrown across it, it would appear as if the aquarium were approached by a rustic arch or subterranean passage. In this passage Ferns would revel; and on the southern side, presuming it to be formed into a rockery, alpine would be charming, whilst the top of the rockery might be planted with *Juniperus procumbens*, *Cotoneaster microphylla*, &c., which would answer the twofold purpose of clothing the rockery as well as shielding the Ferns on the northern side from the burning rays of the sun. Massive lumps of stone are more effective than small ones, and more lasting than trunks of trees in forming the arch. Where any attempt is made to combine rockwork with water, both should be of an irregular shape, or if the water be regular in outline the rockwork should be equally so. If the outline of the rockwork were regular it would be bad taste to have water trickling down or over it, but highly ornamental if it were irregular. Fountains in like manner belong to the polished or regular outline, and should not be employed where irregularity predominates.

Probably the most simple form of aquarium is the pond with grass down to the water's edge, and in such plants grow quite as well as in more costly because elaborate sheets of water. But still water wherever it is in-

roduced should be made in conformity with the surrounding scenery. I have seen a fountain rise from a circular basin and throw water 80 feet into the air in the rustic part of a well-kept garden, and seen in the same place the front of the house disfigured, certainly not ornamented, by rockwork before it. Now, had the fountain changed places with the rockwork it would have been more in accordance with good taste. Fountains belong to polished scenery, and rockwork to the natural or rustic. A basin of water is not improved by anything rustic about it in ornamented ground, but a fountain improves the latter just because throwing water into the air is the result of art, and, consequently, does not appear in nature: therefore it would be unnatural to introduce a fountain in natural scenery.

With these preliminary remarks I will proceed to the construction of the aquarium, polished or natural, for all the difference between one and the other is in the outline and ornamentation. As a general rule, pools of water should be deepest in the middle, and gradually be made shallower as the side or edge is approached. It is not necessary to adhere strictly to this rule, though it is essential to have the water deeper or shallower in one place than another in order to afford facilities for growing as great a variety of plants as possible; yet in basins having a regular outline it is as well to have the basin deepest in the middle, or from 3 to 4 feet deep, and to let that depth prevail over half the width of the basin, and then to form the bottom into terraces as we approach the edge, rising from 3 to 2 feet, then to 1 foot, which should be the depth of the highest step or terrace. The steps should not be less than a foot wide, but as much wider as the width of the basin will allow. In digging out the basin it should be considered how the water is to be kept in. Lead is the most objectionable material, zinc is worse, and cement almost, if not quite as expensive, though the last is not so detrimental to the well-being of the plants as either of the former. I am persuaded nothing is so good as clay puddling, and to make it leak-proof it should not be less than 1 foot in thickness over the bottom, and to the height the water is expected to rise, which should be but a few inches below the level of the surrounding ground. The basin or pool should, therefore, be dug out 1 foot deeper and wider than the depth and size it is expected to have when completed. Very stiff clay is best for this purpose, and it should not be very wet, though it should be moist. Spread a thin layer of clay over the bottom, and ram this down with wooden rammers not more than 6 inches in diameter, rounded a little at the bottom, and made small at top so as to handle nicely, occasionally moistening the clay so as to make it work better and having a bucket of water near in which the rammer is frequently to be dipped to prevent the clay sticking to it.

It is scarcely possible to ram the clay too hard, for unless the interstices be completely closed the water will find its way through. Add more clay and ram this down like the first, continuing to add more clay and to ram until the bottom is completely covered with well-wrought clay to the thickness of 1 foot. A gutter or pipe should be provided at the top to take away the superfluous water, and if a fountain is to be introduced the pipe should be brought into the basin below the surface of the water, but it should be so situated as to be handy for repairs, and not so that the basin would have to be pulled to pieces in order to repair the supply-pipe. It is not unusual to have a statue on a short or low pedestal with the water pouring from the mouth of a snake that has entwined its cold body round the breast and neck of the statue. In others, a basin supported by a column is provided for the water to fall into after it escapes from the jet, which, of course, is situated in the centre of the basin, which last has a furrowed edge, thereby causing the water to fall or drip from it in pearly drops into the pool beneath. I do not think water is at all improved in appearance because it issues from the mouth of a statue, nor consider it more ornamental from an elevated basin than when it proceeds from a jet on a level with the water. I rather incline to the opinion that it is more ornamental by the latter plan than by either of the former. In any case it is simply a matter of taste, for in ornaments of this kind taste varies quite as much as the designs. Still, I cannot forbear remarking that water issuing from the mouth of a serpent, the nostrils of a statue, or mouth of an animal, are an out-

rage on good taste, and not in keeping with the quietude of the surrounding objects. If the jet be on a level with the surface of the water it will be necessary to fix the pipe firmly to something, or it will be liable to become displaced, besides trembling, owing to the pressure of the water, which hinders the water from being delivered steadily in one unbroken column.

A piece of masonry will best serve to secure the supply-pipe in a proper position, for it is easy to let or run lead into it to which the pipe may be soldered. The masonry should rest on the clay, more being put in to prevent its sinking deep into the clay, and so making a way for the water to escape. The clay should not be worked round the masonry, for the water would find its way down by the side of it, and so escape—that is, presuming the masonry to be fixed prior to the puddling. After the puddling has become dry, and it should be left a day or two to do so, and no cracks appearing, as there will be if it has not been rammed sufficiently, throw in as much soil as will cover the bottom 6 inches deep, lessening the quantity so that it will not be covered more than a couple of inches at the edge.

The soil may consist of bog earth, or where that cannot be had, peat one-fourth, rich and rather strong loam one-half, and one-fourth gravel. If, however, the clay has cracked, the rammers must be brought into requisition again, and the clay rammed still firmer, which being done quickly, as it ought to be, allow it to remain a day, and if it shows no disposition to crack put in the soil, and let in the water, taking care that it does not wash the soil down into the deepest part of the basin. Having filled it allow it to stand to see that it does not leak, trying the fountain if there be one.

With regard to the size of the jet, M. François says the diameter should be one-fourth that of the supply-pipe, and he estimates the height of the column of water thrown into the air to be "1 foot below the level of the source for every hundred yards distance." These calculations, however, must be taken with considerable reserve, for the bulk of water at the source has quite as much to do with the height the water is expected to rise. For small fountains where the pressure is not known it is an easy process to ascertain by means of a lead nozzle, the orifice or opening of which can readily be increased or diminished, the width of the opening best adapted to throw the highest and fullest jet of water the pressure is capable of throwing. The width of the basin is quite high enough for any water to be thrown.

This being done and working satisfactorily, the basin will require an edging of stone or some such material of an ornamental character; or an edging of green glass edging-tiles will answer as well as anything, and form an agreeable contrast with the whiteness of the water and grey of the surrounding gravel path. In case there is no fountain the pipe that supplies the basin should be carried in unseen, for no beauty is gained by showing how the water is supplied. Beyond the above a basin needs no other ornaments except the plants, unless the bottom of the jet be considered improved by the raising of some rockwork round it. The idea, however, of water rising from a piled cone of stones is preposterous. Remember, I am writing of water in the midst of an artistic flower garden, where everything is art-supplied, and from which everything natural is excluded. For that reason a flower garden, where the corners of nature are rounded-off, should not contain anything of an irregular outline, or that, whatever it may be, will fail to harmonise.

I may observe that if the pressure be too great it can be lessened by the agency of a stop-tap let into the supply-pipe, so that it may be regulated to throw the water any height; and whilst providing for the conveyance of the water to the aquatic basin, see if a tap cannot be conveniently placed to which the gardener can fasten some india-rubber tubing, and so water the beds in as many minutes as it takes him hours to do with the watering-pot. The beauty of a garden is in proportion to the amount of sunshine in it, and it really is astonishing to see how fast very faces disappear when these little conveniences are given to the gardener.—G. ABBEY.

(To be continued.)

MUS AT HAMBURG GRAPE LOSING ITS FLAVOUR.—I have the Muscat Hamburg Grape worked on the Black Ham-

burgh and Canon Hall Muscat, both of which were full Muscat-flavoured when first ripe; but have now, through hanging, lost every particle of that flavour.

I should be glad to hear through the pages of THE JOURNAL OF HORTICULTURE if any one else has observed the same result? and if such is its habit I will certainly discard it, as it is already subject to shanking very much; and if it also loses its Muscat flavour it is comparatively valueless.—S. TAYLOR, Terrace Villa, Bourbourn, Worcester.

CULTIVATION OF HEATHS.

WHEN I saw the name of Mr. J. Fairbairn at the head of an article on the cultivation of the Heath, I knew from his success as a cultivator of that genus that none could be better qualified to give information upon the subject. Mr. Fairbairn was a man who endeared himself to all who knew him, and members of our craft will always entertain a kindly recollection of him. As it is well known, he was a successful cultivator of *Ericas*, and knowing so well how to grow them he was not one likely to mislead others in describing the treatment of them.

But there are growers of this beautiful genus who differ materially on minor points of culture, although in the main there must be a certain similarity of treatment. For instance: good sandy peat or heath soil is necessary, and no one that I am aware of has succeeded in growing them without it. The difference is in the mode of preparing it, and some of the best growers have peculiar methods of their own in this respect. My object, however, is not to describe the practices of others, but to give my own, and if my remarks are found in any way useful that is all I desire.

A short time ago a correspondent drew a comparison between the cultivation of the Heath and the Fancy Geranium, and in the main appeared to conclude that there is more art in growing the latter well than the former. To a certain extent I perfectly agree with him, and believe that to grow a collection of Fancy Geraniums to perfection requires a degree of skill and nicety that is not easily acquired. But, then, a Fancy Geranium is a plant that can be easily grown if no particular point of excellence is desired; and supposing a gardener who knew very little of the treatment of either, were to undertake to grow a collection of, say, twenty good sorts of Fancy Geraniums, and as many good sorts of Heaths, I will answer for it, that while he might be able to keep the Geraniums alive for a long time, perhaps for years, it is more than probable that the Heaths would soon sicken and die. It is a fact, that while it is the work of a skilful cultivator to produce really good specimen Geraniums, yet Geraniums are grown in nearly every cottage window; but Heaths are rarely seen there at all; and if they do decorate windows, they are merely put there to serve the time while they are in flower, and afterwards are given into the hands of some one who knows how to manage them, and, in instances that I have known, merely to die, or at least to be so far injured that it would be no loss to throw them away at once.

This may not prove that the Heath is more difficult to cultivate than the Geranium, but it shows that the Heath requires a mode of treatment peculiar to itself; and even if the rudiments of that treatment are known, some further knowledge is required, and also a peculiar handling, suggested by the habit of the plant, and acquired only by practice. This, however, is necessary in the cultivation of all plants, and should offer no discouragement in the attempt.

Happily, in this class of plants, as in others, there are species much more easy to cultivate, and which will stand a greater amount of rough treatment than others, and it is always advisable for beginners to ascertain which they are, and commence operations with them. *Erica gracilis* is a very useful sort for flowering in the autumn, winter, and spring; there being two sorts or varieties, one called autumnalis, the other vernalis. I have had the first in flower from October till February, and the latter from February till April. The flowers are small but come in abundance, and are of a bright pink colour, and highly ornamental at a time of the year when flowers are somewhat scarce. This sort I have found to be of the easiest cul-

ture, and also readily propagated, as it strikes very easily from cuttings, which cannot be said of some sorts. But more of propagation presently. *E. hiemalis* is another sort that I consider easy to grow, and a very pretty kind, but it does not last in bloom so long a time as *gracilis*. I have had it regularly in bloom from November until February, so that I may consider it truly a winter-flowering sort. *E. colorans* I have usually in bloom about the same time. It lasts in bloom rather longer than *hiemalis*, is more erect in habit, and not quite so free in growth. The flowers are nearly white at first, but change to a reddish-pink when past their best. *E. mammosa pallida* I have generally had in flower late in the autumn. *E. cerinthoides* has often flowered with me in the winter. *E. Willmoreana* is a spring-flowering sort, and a very strong grower. These are what I have found to be free growers, and such as I believe are suitable to begin with, supposing any one wished to begin cultivating Heaths. The treatment I have usually given them is very simple—merely cutting them down after flowering, and standing them out of doors in May, fully exposed to sun, wind, and rain, housing them in September, and giving them ordinary greenhouse treatment from that time until the beginning of May.

But this sort of treatment will not do for most kinds of Heaths. *E. caffra*, for instance, is a winter-flowering sort, at least so I have found it; but it is of a more delicate constitution, and will not stand the rough treatment described. *E. mutabilis* I have in bloom the whole year round; but this also requires careful management, but the treatment of these is the same as what is necessary for what I call the choice varieties; and as I intend to give the details of my own method of treating them, I will here merely remark that the time of flowering with certain varieties varies much, and that variation depends considerably on the treatment, but sometimes on the season. *E. fastigiata*, *E. lutescens*, and *E. Vernoni*, have flowered with me this season in March and April. The latter is now in full bloom, being the second flowering this season. *E. vestita coccinea* I have usually known to flower in the spring, but this season I have seen it flowering in August. This variation in the time of flowering frequently happens, but a good grower can generally keep them to the proper season. What I consider to be the better sorts of Heaths are mostly summer-flowering, and are often grown for exhibition; but at present I will merely name such as are my own favourites, and what I have had to deal with.

E. ampullacea major.—A compact-growing sort, flowers in July and August; the flowers of a light colour, changing to a reddish hue as they pass their best. This is a characteristic of several others, if not most light-coloured ones. *E. Cavendishii*.—A close compact grower of fine habit and foliage, with deep yellow flowers which open in May and June. This sort is a general favourite. *E. crinita*.—One of the very best; a close compact grower, first-rate habit, and exquisite in the form and colour of its flowers, and usually lasts in bloom a long time. Flowers in June and July. *E. Hartnelli*.—Flowers about the same time as the last; flowers fine and full, but not quite so full and free in habit as the above-named, but good for exhibition. *E. jasmyniflora alba*.—Rather free in habit; one of the best white ones. Flowers same time as last. *E. Massoni*.—This sort I like as well as any Heath grown, both from its habit of growth—the shoots always putting me in mind of the ascent of a rocket—and also on account of its fine flowers, which it produces in June and July. *E. metuliflora bicolor*.—Another favourite, which, when well grown and flowered, is second to none for beauty; but it is not quite so profuse a bloomer as some—at least, so I have found it. Flowers in June and July. *E. retorta major*.—A most profuse bloomer, of excellent habit, compact, and free, hanging over the sides of the pot, and flowering at every point. June and July. *E. tricolor rubra*.—A good sort, as it shows up the flowers well; but rather spare than otherwise in habit. *E. tricolor Wilsoni*.—Good both in flowers and habit. These flower in June, July, and August, consequently are good sorts to grow for exhibition.

The above are known to Heath-growers as good sorts, and there are others equally good; but what I have named would be a good selection, though a small one; and it is always advisable to begin with a few, as before said. Those who have had little to do with this genus had better use a

little caution and begin with the strong-growing sorts, for, after a little practice with such, they will acquire a certain amount of confidence that may soon enable them to handle choicer kinds, it being a consideration that while a small plant of *gracilis* may be bought at a nursery for one shilling, a plant the same size of *Massoni* would most likely cost five shillings, perhaps more.

Most growers differ on several minor points of detail. Almost every Heath-grower has his own peculiar ways and opinions, and I will confess that I have mine; but then nothing suits me better than to learn the exact methods of other growers, so that, if I find their ways better than mine, I gladly adopt them. My object in penning these notes is simply with the idea that others may like to learn from my practice as much as I should like to learn from theirs. I will, therefore, give my experience in detail, and begin first with—

SOIL.—When in the neighbourhood of London I have used a peculiar kind of peat or heath soil such as I have not seen elsewhere. From what I can understand this came from a place in Kent, called, I believe, Shirley, but I am not sure. This peat, with the addition of a little more silver sand than it naturally contained, made a most perfect soil for Heaths, and they were sure to thrive in it; but then this peat may not be obtainable everywhere, so that we must do what we can with the best within reach. Peat earth of some kind it must be, but the more fibry the better—just the mere turf pared off, if possible—the tougher it is and the harder to chop up the better. But even fibry peat may not be at hand, and then, when it is for growing the choicer sorts of Heaths, great care is necessary; and I will just explain how I bring it into a condition that I can trust the roots of Heaths in it. I first chop it up with a spade, and then rub it through a sieve. This latter operation is not necessary, but I prefer doing it for the sake of the rougher fibre, which I consider an important ingredient in the drainage; but if white moss can be obtained that will answer the purpose, and the peat need not be sifted. Whether sifted or not sand must be added—I add about a third of silver sand. If silver sand is not to be had, drift sand or any other sand may be used; but it should be well washed of all earthy matter. The way I have done this is to nearly fill a pail or bucket with sand, fill up with water, stir well, pour off the water, add more, repeat the process until the water runs off clear, then dry the sand, and it is ready to be well incorporated with the peat. Peat itself without sand, or with very little, is a very unsuitable soil for putting any plant in. When wet it soon turns sour, and if it once becomes thoroughly dry, it is difficult to make it properly moist again. Plenty of sand mixed with it makes it both porous and absorbent. Any kind of well-washed sand will accomplish this object, and will do provided there is no pernicious quality in it. Silver sand, however, is best; and even if another kind of sand is used it is still advisable to mix some of this with the soil, since it is said that the Heath derives its silica from it; it, therefore, supplies an article of food. But, in addition to sand, I invariably mix with the peat a large quantity of broken pots. This I consider most useful, for it makes the soil still more porous and absorbent, and there is little chance of the soil becoming sour. The soil when ready for potting is about one-half peat, the other half equal portions of sand and broken pots.

POTTING requires a little care and skill, for much of the success depends on it; indeed, so much so that I can scarcely consider a plant under control unless I know how it has been potted. In the first place the pot should be thoroughly clean, and just dry enough to show no moisture on it. If too dry it is apt to absorb the moisture from the soil. The plant about to be potted should be just nicely moist, neither more nor less so than the soil to be used in potting. The pots should be nearly drained, and this does not depend on the quantity of drainage, but on its arrangement. I generally first put a crack over the hole, convex side upwards. I quite agree that it is a good plan to place it convex side downwards in order to keep worms out of the pot, but I never like placing Heaths where worms have a chance of getting in. When I do I place pieces rather smaller, and cover with the broken smaller still, but not fine, over this a thin layer of peat fibre, then a little soil. It is then ready for the plant, which should be placed at the proper

height, simply taking care not to bury the collar and to leave room for water. I generally use a blunted stick to press the soil together, but take care that it is merely rendered solid and not hard.—F. CHITTY.

(To be continued.)

TREATMENT OF CYANOPHYLLUM MAGNIFICUM.

If I cut down a *Cyanophyllum magnificum* would it shoot again? or if I partially cut it down would it shoot out from the side, and become again a good plant? At present it is a magnificent plant, but too large for my stove. Although only bought about a year ago, and then about 1 foot high, it is now 3 feet 7 inches high; the large leaves are 13 inches wide and 29½ long. I should be glad also to be told how to propagate it, and at the same time to have a list of six new stove plants, and six ornamental-foliaged stove plants.—M. G.

[You have grown that *Cyanophyllum magnificum* with leaves 29½ inches long and 13 wide very well indeed. We should be loath to cut down so fine a plant, but as it is a necessity, could not you exchange for a young plant with some neighbour? It is a pity to cut it down, for this plant, although it stands cutting down, seldom makes a fine specimen afterwards. You can cut it down at your convenience, it will shoot again from the dormant eyes on the stem. It may be cut down to the lowest pair of eyes, or, to make sure, to the second pair or joint. It strikes pretty freely from cuttings. The tops of the shoots are best for striking—say with three joints. Take off the lowest pair of leaves, and cut the bottom transversely immediately below the lowest joint. Insert the cuttings singly in a No. 48-pot in sandy peat, leaf mould, and loam, with an equal quantity of silver sand intermixed. Plunge the pot, after gently watering, in a bottom heat of 85°, and cover with a bell-glass if the atmosphere be in the least dry. Keep the soil and the atmosphere moist for about six weeks, when the cuttings will be well rooted. This plant may also be propagated from eyes of the young and old wood like a Vine, inserting them half an inch below the surface, and placing in bottom heat and covering with a bell-glass as for cuttings.]

Of new plants let out, choose *Ixora crocata* superba, *Stenogaster concinna*, *Calliandra hamatocephala*, *Gesnera pyramidalis*, *G. refulgens*, and *Hebeclinium atro-rubens*; of fine foliage, *Alocasia zebrina* and *Lowii*, *Pandanus elegantissimus*, *Hibiscus Cooperi*, *Theophrasta imperialis*, and *Campylobotrys refulgens*. If you wish for newer consult the reports of the various shows published in our pages, or visit some large nursery where you can choose for yourself.]

MELONS NOT COMING TO PERFECTION.

I HAVE for the last two years been very much troubled at my Melons not coming to perfection. I attribute this to the strong growth they make. I attempt to grow them in close brick pits, without the aid of hot-water pipes, by filling the pits with hot dung and leaves mixed together. I shake these materials well to pieces in order that the mass may heat regularly. After it has sunk I place some old turf, with the sword downwards, about 2 inches thick, all over the dung. On this I place about two bushels of a compost of fibry loam and old turf, &c., for the reception of the plants, which I plant out three in each hill. There is a hill to each light, each of which measures 24 square feet. After planting I water them with a little water with the chill off, and syringe them every afternoon with water of the same temperature as the air of the pits. I give as much air as is consistent with the culture of the Melon. They grow very fast, and a great deal too strong to do much good. They set their fruit very freely and swell until they attain the size of a cricket-ball or a trifle larger. By this time the vine or the stem just above the surface begins to show symptoms of decay. The plants then begin to die away by degrees, and ultimately the whole of the vine is withered up, leaving the fruit destitute of nourishment. I have grown the Melon with great success in some of the largest places in England and Scotland in pits heated by hot water,

and likewise on dung-beds; but what I want to know is if any one has been visited by the same evil? If so, I should like to know if he can suggest any preventive?—J. E. C. P.

[Your case is by no means a singular one, and from what you say it is evident that your Melons have been destroyed by canker at the root, or rather at the main stem of the plants just at the surface of the soil. This disease is easily detected by the enlarged corky-like appearance at the neck of the plants, and is most frequently attendant on a strong plethoric growth such as you describe your plants to have made. When the disease appears the best means of counteracting it is to thickly dust the affected part with quicklime; but this does not always prevent it. From what you say it strikes us that you grow your Melons in rather too light and turfy a soil, and that you water too frequently; and if you were to use a heavy rather clayey loam with no manure mixed with it, putting a good depth of soil in your frame, and treading it firmly together, and to apply water seldomer but in greater quantity at a time, you would find that your Melons would not grow so rankly, and be less subject to go off as you describe. We have always found two or three good waterings sufficient to bring a crop of Melons to maturity when a good depth of heavy soil has been used, and under such circumstances they are less liable to canker.]

WELL HEAD.

(Concluded from page 213.)

In stepping out of the Orchard-house a fine plant of the Australian Pitcher-plant, *Cephalotus follicularis*, in the show-house again attracted my attention; and as Mr. Baynes is very fortunate in his treatment of this and many more rare and curious plants, and very liberal in imparting his knowledge, I will give the treatment he pursues so advantageously. *Cephalotus follicularis* delights in a humid atmosphere, and what may be termed a warm greenhouse temperature suits it exactly. It does best when in a small pot enclosed in a larger one, the interval filled up with sphagnum. The compost in which it is potted consists of sphagnum and fibry peat in equal parts, the main point being to provide good and perfect drainage. It is necessary to place the pot in a feeder of water, and to cover the plant with a glass fitting the inside of the outer pot if the house in which it is placed is at all dry, but not where the atmosphere is humid or very moist. The glass should be taken off and wiped occasionally, which prevents the plant being surrounded by stagnant air.

Without much time after leaving the Orchard-house to enjoy the pure air, we enter a vinery 30 feet by 18, with a half-span roof. The border is inside entirely, about 20 inches deep, and composed of the top spit of a pasture incorporated with about one-tenth charcoal and uncrushed bones. The house is well heated by four pipes along the front and two at the back, which permit of keeping up the temperature to the proper pitch without making the pipes very hot, and, what is better, air is admitted below them in front, whilst at the back the pipes are enclosed in a drain. In both cases no cold air can under any circumstances pass into the house without becoming heated. Ample provision is also made to let out the heated air at the top of the house.

The Vines are carrying half a dozen bunches each, this being the second season from planting. The sorts are Bowood Muscat, a very fine Grape, in my opinion the best of all Muscats; Black Hamburg, like sloes in colour; White and Charlesworth Tokay; Royal Muscadine; Champion Hamburg, a very fine even-berried buncher; and Muscat Hamburg, a very fine flavoured Grape, rich and vinous, with the peculiar flavour of the Muscat, but shanked; but I do not think outside planting has anything to do with that. The Frontignans shank quite as much planted inside as when planted outside, and so do many others. I am persuaded Frontignans shank through a deficiency in the component parts of the compost. Grizzly Frontignans were here the colour of badly-ripened Hamburgs, and were very fine indeed. In some pots were layers fed from the parent as well as the pot, carrying large bunches in proportion to the size of the pots, and although inadmissible for

exhibiting, they nevertheless form useful subjects for the dinner-table, where large fruit is preferable to that generally yielded from pots: the size and weight of the pot being a matter of some import also in matters of this kind.

In this house, too, were several *Amaryllides* and a great quantity of *Vallota purpurea*. Adjoining is a late vinery, rather in front of the other, which is identical with the other in every respect except the varieties, among which was *Lady Downes*, not only the best of all long-keeping Grapes, but as good as a Hamburg when ripe, and not like the *Barbarossa* and some others, which require to be turned into raisins before they are fit to eat. Golden Hamburg is not worth growing in my estimation, though Mr. Baynes has some very fine fruit upon his Vines. There were also Mill Hill Hamburg, Muscat Hamburg, and Trentham Black, well worthy of the name, as it is a very fine Grape though small in berry. The crops on these Vines are excellent and do great credit to the manager. In pots were some strong canes ripening their wood well.

The next house is approached by descending some steps, and is a Cucumber-house 27 feet by 15, which is heated by hot water for both top and bottom heat. In it I noticed some good fruit of Kirklee's Defiance, a free winter-fruited variety; Champion; and a sort of local repute, Robin Hood, which judging from appearance is a desirable variety. Here, too, were several seedling *Stephanotis* from *floribunda* with the midrib of the leaves red. I only remember having once seen the *Stephanotis* in fruit, but I never saw seedlings raised from it before. The seedlings are very promising. Let us hope they may give scarlet and blue flowers with the perfume of the parent.

Close to the last house is the Azalea-house, 27 feet by 15, in which are good plants of all the leading kinds and studded with bloom-buds. The plants are not large, but neatly trained in the shape of pyramids and bushes. For my part I prefer a moderate-sized specimen to one that takes up the space occupied by a dozen smaller plants. I can see more beauty in variety than sameness, and, consequently derive more pleasure from examining a dozen representatives of a genus than a huge plant whose beauties are seen at first sight. In this house were three new *Rhododendrons*—*Princess Royal*, *Veitchi*, and *Præcox superbum*; also *Centaurea ragusina*, more shining in colour than *C. argentea*.

A little further on are some of those useful appendages to every garden—cold pits; and in them were some things from which Mr. Beaton would have drawn some instructive conclusions, but I must be content to note them—viz., boxes containing seedling *Rhododendrons*, *Dalhousie* crossed with *Broughtoni*, *Broughtoni* crossed with *Dalhousie*, *Edgworthi* crossed with *Broughtoni*, and *vice versa*; *Dalhousie* with *Princess Victoria*, and *Dalhousie* with *Edgworthi*. The pits also contained some softwooded stuff—as *Cinerarias*, *Primulas*, &c.

Mr. Baynes showed me his boiler, which is Ormson's No. 5, heating ten compartments satisfactorily. It consumes about two tons of coke per week, does the work of ten saddle boilers, or twenty flues, presuming that mode of heating were adopted, and gives every satisfaction. Mr. Baynes is opposed to flues, and reckons them amongst the things of the past.

In journeying towards the other houses we meet with a large Tulip Tree, which is very fine, and appears to stand smoke well. The Yews, alas! are fast succumbing to the smoky atmosphere, which cuts off *Conifers* as frost does early blossoms. A bed of hardy *Statice* on the lawn is very pretty, and one often wonders that such plants are not more generally cultivated; and why everybody should pass over that fine old herbaceous plant, *Onosma tauricum*, the flowers of which rival any yellow *Calceolaria*, is, indeed, marvellous. Its propagation was said by a contemporary to be difficult, but Mr. Baynes strikes it by layers as freely as a *Carnation*.

But of the very many charms to be seen at this interesting place, none are more worth seeing than a plant of *Lapageria rosea*, which had fifty flowers expanded when I saw it (August 18th), and several green ones coming on. It occupies the northern half of the Heath-house, a small span-roofed structure 22 feet by 18, and is trained near to the glass. It is planted in what I will term a bed 4 feet long,

and 18 inches wide by 20 inches deep, with 20 inches of drainage below that. The soil is rough peat, with a liberal admixture of pieces of charcoal. It receives about four gallons of water daily, and is never subjected to any heat beyond that given to the Heaths and Epacris in winter, or about 45° on an average.

The Heaths and Epacris are now outside, but the house contained a good collection of Geraniums of the best sorts in flower, and amongst them I noticed a seedling of Mr. Baynes's much in the way of Wonderful, with large trusses and bold flowers, some trusses consisting of a dozen blooms. Although, perhaps, of no merit when under the eye of a florist, yet it is a very useful variety for conservatory decoration.
